DAYTON, O.—Editor THE AUTOMOBILE—We believe it will be of interest to you to know that we have overcome the complaint of dazzling headlights for automobiles, and the large business which we have secured is sufficient proof that we have solved this problem.

Instead of using a special dimming device for reducing the glare, a special reflector is used in the construction of our automobile headlights. This reflector is a parabolic lens mirror of a golden tint made from the highest grade of optical glass. The glass parabola is coated with a pure silver backing, and this is covered with a protecting layer of metallic copper. An aluminum finish is given to the copper to prevent tarnishing.

Glaring White Element Eliminated

This yellow tinted mirror overcomes the blinding glare so apparent where a silver reflector is used. The glaring white element is entirely absent, as the golden tint absorbs the ultra-violet rays to a great extent. This reduces the glare, at the same time furnishing a light which will penetrate fog and dust to a greater extent than the rays of light from a silver reflector.

The rays of light are just as powerful as from any other lamp. The light so nearly duplicates daylight that objects along the road are not distorted, neither are holes or rough places in the road magnified.—THE APPLE ELECTRIC CO.

Favors Extreme Simplicity in Design for Service and Economy

ROCHESTER, N. Y.—Editor THE AUTOMOBILE:—The Society of Automobile Engineers, at their recent convention at Cape May, N. J., considered the subject of the Ideal Car of sufficient interest and importance to have papers prepared and read regarding it. Since then we have heard very little about it, though the fact that this eminent body had discussed the pros and cons of the car of the future would seem to indicate that at least a few of our many enthusiastic automobilists would have some opinions on the subject to offer.

When THE AUTOMOBILE conducted a department entitled The Ideal Car, a year or two ago, I was one of its readers who ventured to contribute my conception of the subject. And since that time the developments of engineering practice, design and construction have only served to strengthen my belief that the ideal car is one which will give a maximum of service with a minimum of trouble, care and expense.

Building the Car Simple

For the past 7 years I have been an automobile owner and my experience has been that the more parts and attachments a car has the more things there are to get out of order, and, consequently, the higher is the proportion of probability that when you take the car out something will go wrong, either on the road or soon after the return from the trip.

In view of this, as our modern cars became more complicated and I found that most of my spare time was being consumed in taking care of any number of more or less superfluous devices, which were described in the catalogues as luxuries, I determined to emancipate myself from these cares of complication and, accordingly, purchased a stripped chassis of well-known make with none of the fashionable excrescences which I wished to avoid. I fitted up this chassis with the simple necessities and discarded everything possible without impairing comfort and serviceability and the result is that I have a car with which I can travel for weeks at a time without any other care than keeping up lubrication, cooling water and fuel supplies.—A. L. BOOTH, M. E.

Recent Court Decisions—Wagon on Highway

By George F. Kaiser

NEW YORK COURT says that when a teamster stops his wagon diagonally across the highway, leaving insufficient space for an automobile to pass in the rear of the wagon, when the car is in plain sight, he is guilty of negligence, and the employer must stand for any damages which result to the automobile by reason of the same.

An automobile was coasting on a down grade at a speed of about 20 miles an hour. About 330 feet from a depression at the side of the road, a teamster came along the lane toward the highway. As the team reached the highway, the motorist blew his horn, and the teamster looked up and then stopped his wagon diagonally across the road, leaving insufficient room for the motorist to pass. The motorist attempted to throw his gear into the reverse, but was unable to do so because the gear caught. He then attempted to pass in front of the horses, but the automobile fell into the depression, and the car finally struck a telephone pole.

The car was damaged, and the motorist sued the wagon owner, and recovered a judgment to the sum of $200.15. The owner of the wagon appealed the case, but the higher court said that the judgment in favor of the motorist was proper, as the negligence was all on the part of the driver of the wagon, and because of this negligence the accident occurred.—*Manion vs. Loomis Sanatorium*, 162 N. Y. Appel. Div. N. Y. 421.

Motorist vs. Motorist for Collision

In an action in the Rhode Island Court, where one motorist sued another motorist for damage caused by a collision when they were both going in the same direction on a broad highway, the Court said that the questions which determined the liability of the respective motorists were: "Did the plaintiff (the injured motorist) at the time and place of the collision leave room enough at his left for the defendant to pass him in safety and without striking his machine?" and "Did he block the road ahead of the other car before the other party attempted to pass him?"

In this case one motorist sued another for damage caused by a collision. Both cars were going at a moderate speed in the same direction along a highway which was 25 feet wide and on which no other vehicles were at the time. It seems that some time previous to the accident words had passed between the respective drivers of the cars because of the fact that the car ahead slowed up suddenly at a railroad crossing without giving any warning and the rear car nearly crashed into it.

The Court found that the party against whom the suit was brought was not liable as the one bringing the suit failed to prove the law of Massachusetts, which provides that one car shall pass another on the left and shall not turn until there is ample room to clear the car which has been passed. On the failure to prove this law the common law was held to be in force, under which one vehicle was not obliged to turn off for another coming from behind if there was sufficient room for the other car to pass on either side with safety.—*O'Donnell vs. Johnson*, 90 *Atlantic* (*R. I.*), 165.

Policeman Loses Case

New York Court says that when a police officer is riding in an automobile in the course of his duty, and is injured by reason of one of the wheels collapsing, he must nevertheless prove negligence on the part of the city or chauffeur before he can recover damages.

In this case, while a policeman who had been assigned to the Department of Finance, was accompanying a paymaster in the Croton Aqueduct, he was injured by reason of one of the wheels collapsing on striking a large stone. The car turned over, and the policeman and another man were killed.

His administratrix brought an action to recover for his death, and although the trial court gave judgment in her favor in the sum of $7,000, the higher court decided when the city appealed, the court made a mistake in not putting the burden of proof of negligence on the administratrix, and further before her recovery could be had against the City it was necessary to show that the chauffeur was in an intoxicated condition, or was driving the car recklessly or in an improper manner.—*McCormack vs. City of New York*, 162 Appel. Div. N. Y. 539.

The Rostrum

Two-Cycle Motors Favored In Large Installations

EDITOR THE AUTOMOBILE:—I notice in the Rostrum this week E. R. Crilley, "Thinks Two-Cycle Motors are Passé." I would suggest that the correspondent get in touch with a well-equipped public library and take a few notes before he condemns a principle he evidently does not understand. I would suggest that he study *Engineering* and *The Engineer* of London, *The Gas Engine*, Cincinnati, Ohio, and note where the two-cycle engine is being used in preference to the 1876 principle.

Following are extracts to prove my claim:

Engineering, London, April 24, 1914, The development of High Power Marine Engines. In considering the future possibilities, *only* the two-stroke cycle will be dealt with, as the power of the four-cycle engine is limited by the difficulties of dealing with the exhaust. The weight and space occupied by the two-cycle engine is not great. To obtain the maximum actual mean effective pressure per revolution, the two-cycle engine will be adopted.

The Gas Engine, Cincinnati, January, 1914, page 47, Krupp builds six-cylinder, two-cycle engines for submarines, 900 horsepower. *The Gas Engine*, February, 1914, page 74, Development of the submarine, with the French and German submarines in which the two-stroke engines have been most common, compressors are of course used.

The Gas Engine, August, 1914, page 505: A larger two-stroke cycle engine than this has been built however. This is a six-cylinder engine of 4,000 horsepower built by Sulzer Brothers, a single acting two-stroke cylinder has been built for experimental purposes for which 1,500 to 1,800 horsepower was obtained without serious difficulty.

Finally, Mr. Knight had to take his American design to England to be appreciated. Europe won the first four prizes at the International races at Indianapolis. They have some new valve gears that are positive in action. I will venture to predict the fashion may get a jar due to progressive work along two-cycle lines where some of the leading concerns are busy trying to eliminate inherent defect in the 1876 principle.

Cleveland, O. LABOR OMNIA VINCIT.

How to Install a Unisparker

Editor THE AUTOMOBILE:—1—Kindly explain and show by diagram the manner of installing an Atwater-Kent Unisparker on a Model F Buick Car.

2—The non-distribution type igniter produces a spark in both cylinders at the same time and, as I understand it, the current flows from one coil to both cylinders, dividing, as it were, into two streams. Is this so, and is not the spark weakened?

3—Would better ignition on my car be secured if I used a spark plug with a long lower end? The wall of cylinder at spark plug hole is 1 3-8 inches deep and with an ordinary plug the electrodes reach down only about 5-8 inch. It seems to me that if the electrodes reached through the hole the lower end of plug would be kept more free from soot.

4—In assembling my car I found two marks on the camshaft gearing and it was impossible for me to know which one to go by. The difference amounts to one tooth or, if a mark on the angle of the crankshaft is taken into account, two teeth. Explain how the gears must be set.

5—I have battery ignition on my car. Would it be good practice to connect an electric horn to the set of batteries used for ignition?

Iowa Park, Texas. HORSELESS.

—1—The Atwater-Kent Unisparker is attached to the timer shaft after removing the commutator. The loose gear is then placed in the bracket, Fig. 3. The bracket is put on the bronze bushing which forms the bearing for the timer shaft, making the inside of the bracket even with the face of the bushing and the loose gear on the timer shaft. Then clamp the bracket by securely tightening the two set screws. Finally adjust the loose gear to run smoothly with the other one. Drill and pin the loose gear to the timer shaft.

The timing of the Unisparker is accomplished by bringing the piston in one of the cylinders to top dead center on the compression stroke. Turn the motor over until the mark on the flywheel indicates that the pistons are on dead center and then determine which cylinder is on its firing stroke by noting which cylinder has both valves closed.

Then, with the spark lever retarded, set the breaker mechanism so that the contacts breaking the circuit to the spark plug in this cylinder are just ready to separate. The timing adjustment is obtained by loosening the screw on the collar of the Unisparker.

The only other adjustment is the width of gap at the contact points. The space should be between 1-32 and 1-64 inch, depending upon the strength of the batteries, spark heat required, etc. The spark can be made hotter by decreasing this distance and current economized by increasing the distance. Once or twice a season these contacts should be examined and if rough should be smoothed off by means of a fine file or a piece of

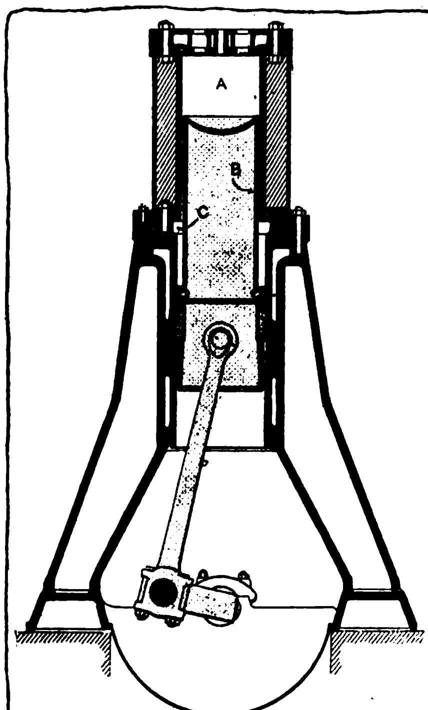

Fig. 2—Motor with uncooled cylinder. The upper part of the piston does not touch the hot cylinder. Note packing at C

emery cloth on a flat stick. The proper adjustment when starting with new dry cells is about 1-32 inch and if a storage battery is used this may be reduced a trifle. At intervals of 600 or 800 miles these contacts should be closed from a quarter to a half a turn, or until regular firing is again obtained. Do not atempt under any circumstances to adjust the tension of the springs.

2—Where the current is not distributed but is allowed to flow to both spark plugs each time that a spark is needed in one, naturally, twice as much current must be used as in a system using a distributer.

3—Some improvement in the operation of the motor will be noted if longer spark plugs are used. You should be able to obtain these spark plugs from any supply dealer.

4—You had better check up the timing by means of the marks on the flywheel. There are two marks quite close together on the flywheel rim. The first one, considering the direction of rotation of the motor, is for exhaust closing, and the second, for intake opening.

5—You do not state whether your battery ignition is of the storage or dry-cell type. If it is the latter, it would be safer to have an extra set of cells for the horn so that there will be no danger of weakening the cells that you are depending on for your ignition.

Reader Designs Novel Limousine

Editor THE AUTOMOBILE:—It seems to me that there is not enough originality to our body design. Nearly every touring car is like every other one and the same applies to closed machines. Furthermore, a body should be practical as well as good looking yet there are many that do not satisfy more than one of these requirements.

A closed body design that departs from standard practice to a large extent is shown in Fig. 1 yet it has many good points and it carries out the streamline idea with more unity than any other design I have seen.

A high V-pointed radiator is used in connection with a sloping hood. The front of the roof slants over to meet the end of the hood, the width of the glass panel only being about 18 inches. Thus the hood makes an almost unbroken line with the roof.

The ideal chassis for such a body should have a four-cylinder motor, with cylinders 4.5 by 6 inches, of medium speed. A cone clutch and three-speed gearset should also be used.

Nor is the roof of the body so low that the passengers are likely to strike their heads, because the floor of the car is underslung from the frame so that it is only 10 inches from the ground—the same as the clearance under the axles and the flywheel. In the ordinary limousine the floor is 20 inches above the ground, so 10 inches is gained in this manner, in other words the car can be made 10 inches lower.

The streamline effect is further accentuated by carrying the sides of the body down to hide the frame members and by fitting bicycle-type fenders that hug the wheels as closely as possible. The doors have invisible edges.

A small objection to this type of body, of course, is the fact that the flooring must be arched over the gearbox and driveshaft but this is of small moment.

Utica, N. Y. F. L. ADAMS.

A Motor Without Cooling

Editor THE AUTOMOBILE:—Do you know whether anyone has ever tried to design a motor without provision for cooling the cylinders. It seems to me that it would be possible to construct a long piston, the lower part of which would be used as a guide, and would not come into direct contact with the hot gases and the upper part would be of slightly smaller diameter so that it would not come into contact with the uncooled walls of the cylinder yet the space between this part and the piston would be so small that no hot gases would pass down to the lower part of the piston, which would be a running fit.

Brockton, Mass. H. E. B.

—This was suggested several years ago by a Frenchman, by the name of Gardee, and while it is not adapted to automobile work it might prove satisfactory for stationary engine service.

As will be seen by the section of the motor shown in Fig. 2, the lower part of the piston works at low temperatures because between the hot part of the motor A and the lubricated piston there is an annular body of gas B which prevents the heat from being transmitted.

It will be noted that such a motor would be too high for automobile work and that the reciprocating parts would be too heavy for the speed required by present-day practice.

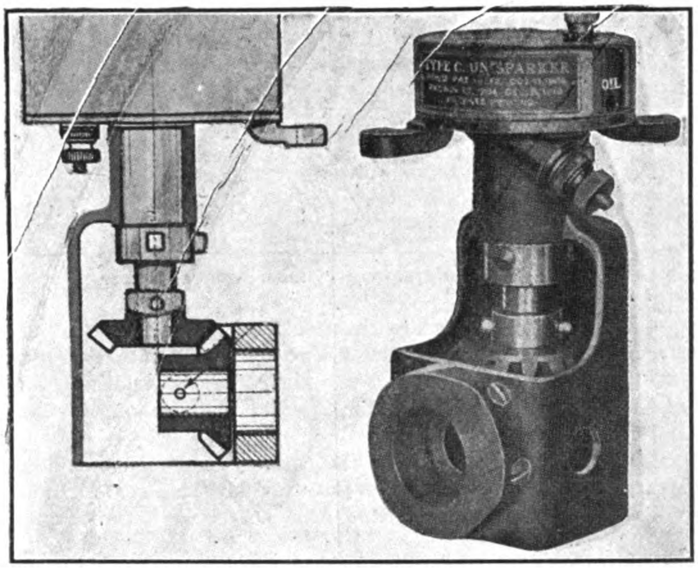

Fig. 3—Atwater-Kent Unisparker for model F Buick

Information Concerning Buick C 37

Editor THE AUTOMOBILE:—Kindly give me the following information concerning the Buick 1915, model C 37:

1—Maximum number of revolutions per minute.

2—Gear ratio on high gear.

3—Maximum speed.

4—Weight fully equipped.

5—Also how can demountable rims be kept from rusting?

Christiansburg, Va. T. H. WADE.

—1—The maximum revolutions per minute of the motor is 1,900.

2—The gear ratio on direct drive is 4 to 1.

3—The maximum speed is 50 miles per hour.

4—The weight is 2,950.

5—Demountable rims may be kept from rusting by painting with a good flexible enamel. Clean the rims thoroughly first, and then paint them. Rusting of the rim where it comes into contact with the bead of the tire can be prevented by painting the rim before the tire is put on, with flake graphite mixed up with enough gasoline to make it fluid.

No Companies Selling on Installments

Editor THE AUTOMOBILE:—What automobile company is it that sells its cars on the installment plan, to both the agent and final purchaser? I did not know until a few days ago, that any company was offering such a proposition, but an agent here showed me part of a letter from some company—he would not show me the name—offering to do this.

Windsor, Mo. GEO. P. JAMES.

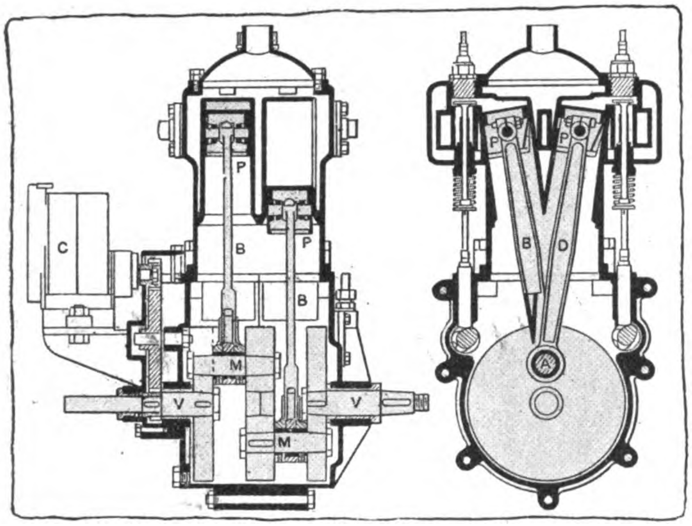

Fig. 4—Two views of four-cylinder V-block motor

—We know of no concern that makes a specialty of selling cars on the installment plan. Undoubtedly some concerns have allowed dealers to pay for their cars in installments where it was desired to offer special inducements to the dealers to take the cars.

Here and there throughout the country dealers are selling cars on the installment plan but this is a matter for the individual dealer to decide and does not concern the manufacturer.

The fact that the dealer you speak of would not let you see the letter would seem to indicate that the understanding was confidential and that the manufacturer was not making similar terms to other dealers.

Explanation of Four-Cylinder V Block

Editor THE AUTOMOBILE:—The other day I was examining a motor which seemed to be of the two-cylinder type with the cylinders cast in a block. I was under the impression that it was an extraordinarily large diametered motor and on inquiring found that it was a four-cylinder motor with the cylinders alongside of each other. Will you kindly show me by means of a diagram how these cylinders are placed?

Hoboken, N. J. CHAS. STEARNS.

—The motor described by you is shown in section in Fig. 4. It is seen that the cylinders are inclined to form a V-shape with each pair of connecting-rods working on the same crank. There are three flywheels within the motor which are connected to the cranks and crankshaft in the manner shown in the longitudinal section through the motor.

Description of Oakland Ignition

Editor THE AUTOMOBILE:—Will you please give me a description of the ignition system used on the Oakland six 48? In the instruction book furnished by the Delco company, I did not quite understand how the current passes to the distributer, from the dry cells, and from the generator.

Buffalo, New York. HENRY J. SLEZAK.

—The Delco ignition system, Fig. 6, used on the Oakland 48, consists of a dual automatic distributer and timer which is carried on the left side of the motor near the front, and a coil for transforming the low-tension current into high-tension.

When ignition current is supplied from the lighting circuit the current passes from the storage battery or the generator, depending on which is furnishing the current, through the switch, and on out through wire A to the low-tension winding of the coil, from whence it passes to the timer and from there to the frame where it is grounded.

The high-tension current generated in the coil runs to the distributer where it is switched to the spark plugs in different cylinders in turn. This current is produced by the magnetic reaction due to the sudden subsidence of current in the primary.

It will be noted that there is a resistance unit just above the timer on the diagram. This is for the purpose of protecting the circuit. Under ordinary conditions the wire remains cool and offers little resistance to the passage of current, but if for any reason the primary circuit should remain closed for any length of time this wire will become heated, its resistance will increase and in this way will reduce the amount of current flowing. In other words this resistance coil becomes heated and reduces the flow of current before the current can injure any other part of the circuit.

Directly above the resistance unit is a condenser.

When the dry cells are used for ignition the operation is the same except that a device called an ignition relay, Fig. 6, is added to the circuit. This device economizes current by breaking the circuit immediately after it has been completed by the time contacts. Thus the circuit is closed a much shorter time than is the case when the circuit is broken by the timer contacts themselves.

How to Install an Ammeter

Editor THE AUTOMOBILE:—Will you please describe a method of attaching an ammeter on a 1914 Buick, Model 25, equipped with the Delco starting and lighting system?

How many miles per hour does this car have to travel to begin charging the storage battery?

Keokuk, Ia. EDWARD MOORE.

—Although you have not stated it, you probably desire to measure the rate of charge and discharge of the battery, and not the consumption of the lights when the generator is supplying the current, etc. The connections are very simple as it is only necessary to place the ammeter in series with either one of the cables running to the storage battery. Cut the cable in two at whichever side is more convenient and attach the ends of the wire to the terminals on the ammeter.

Relative Positions of Armature to Pistons

Editor THE AUTOMOBILE:—As a subscriber to your magazine I take the liberty of asking some information on the correct relative armature positions when compared to the positions of the connecting-rod and timer for different positions of the spark. That is, for a retarded or advanced spark. Can you enlighten me?

Macon, Ga. H. E. LORD.

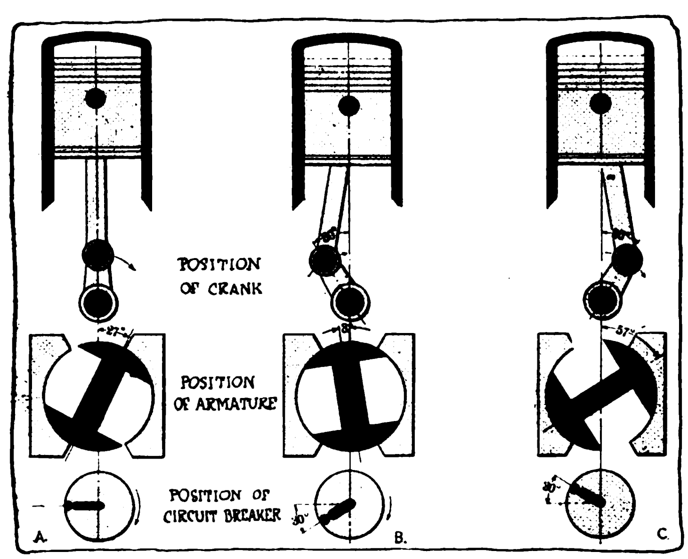

Fig. 5—Diagram showing position of armature for different crank pistons

—The relative positions of the piston and connecting-rod to the armature and the contact-breaker can best be shown by means of a diagram. Such a diagram is given in Fig. 5. The direction of rotation is clockwise, and the maximum spark advance and retardation have been taken as 30 degrees. The position of the armature is so designed that the maximum current will be obtained under the greatest number of conditions of spark advance or retardation.

Differential Gears Hum on Turns

Editor THE AUTOMOBILE:—I have a 1910 car that is in good repair with the exception that the rear axle makes a noise. The noise is not so bad except when I turn a corner. About one year ago I returned the drive shafts and differential to the maker and had a new housing and gears put in. Since then I have put in a new bevel gear driving pinion. If I screw the pinion up as tight as I think it ought to go, it binds.

2—Does it make any difference how many teeth are in a bevel gear in relation to the gear it works in?

Pittsburgh, Pa. R. A. JENKS.

—1—This condition is due to the shifting of the large differential gear so that it moves away from and toward the driving pinion. The cause of this is usually a loose truss rod which permits the housing halves to separate. The left half of the housing should be removed and the bolts reset and tightened and then the truss rod taken up as far as possible to form a rigid construction. If you are not familiar with the work do not attempt it, and under no circumstances should you try to readjust the gears to compensate for the loose rod.

2—The relation of the number of teeth on the driving pinion to the number on the large gear gives the ratio between the number of revolutions the motor makes as compared with the number the wheels make when the car is traveling on high gear. Any change in either the pinion or bevel gear, alters the ratio.

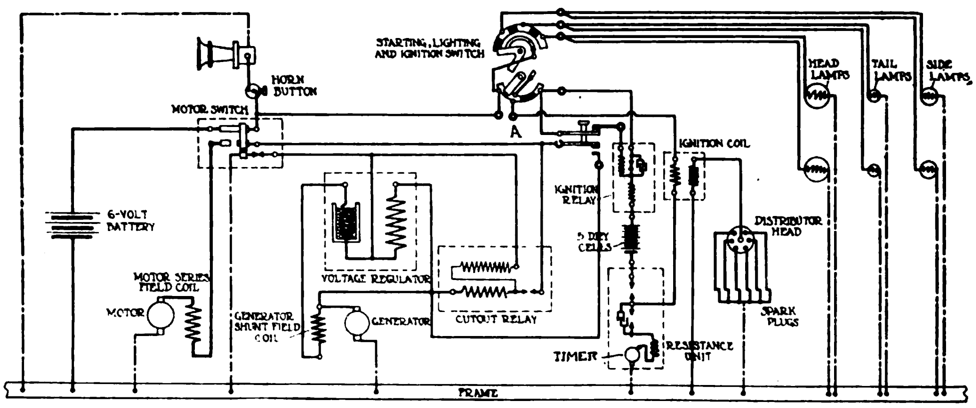

Fig. 6—Delco system used on Oakland six showing method of distributing current to spark plugs

Speed Changes on Electric Cars

Editor THE AUTOMOBILE:—1—Do not the Stearns, Columbia, Palmer-Singer and Moline cars use rotary valve motors?

2—Has a three-point suspension motor any advantages over any other?

3—Has the automobile made the fastest speed made by any vehicle? What is the fastest mile ever traveled, and by whom?

4—Has an electric car any gears or only one speed?

5—How many revolutions per minute will a 36-inch rear wheel make when the car is going 45 miles per hour?

6—What is the S. A. E. rating of a 6-inch, four-cylinder motor?

7—Is the facing used on the clutch of the 1912 Overland made of leather?

8—Could the 1912 Overland, which has a Kenwood oiler, be changed to have a splash system of lubrication without excessive cost?

Conneaut, O. F. A. WAHL.

—1—None of the cars you mention use rotary-valve motors. The Stearns, Columbia and Moline have the Knight sleeve valves. The Palmer-Singer has no rotary valve. The Speedwell is the only car using a rotary valve engine.

2—Adherents of three-point suspension for the motor believe that hanging the engine on three points prevents strains in the engine base and crankshaft due to twists which occur in the frame due to the unevenness of the roads.

3—The fastest mile ever traveled, of which there is an official record, is Bob Burman's mile in the Blitzen Benz, made at Daytona, Fla., April 24, 1911, at a speed of 141.73 miles per hour. Duray, in the 300-horsepower Fiat, traveled a kilometer at the speed of 142.9 miles per hour at Ostend, December 16, 1913, but the official record was not procured for the European regulations called for the distance being covered in both directions. This is the fastest speed ever made in a motor-propelled vehicle.

4—Electric cars in general do not have a speed change similar to that in the gasoline car. They have a number of speed changes, from three to seven, which are obtained by varying the connections between the battery and the motor and inserting resistances in the motor winding, in exactly the same way as it is accomplished in the electric street car.

5—Four hundred and twenty revolutions per minute.

6—The horsepower is 57.7.

7—Yes.

8—It is not believed that the advantages of the change would pay for the cost.

Questions Concerning Cadillac

Editor THE AUTOMOBILE:—To what extent did the Cadillac experiment with the six-cylinder motor?

2—What was the first car to use the two-speed rear axle, and who uses them today?

3—Who makes the front and rear axles, radiator, body, wheels, rims, and lamps of the Cadillac, and who makes their frame?

4—Does the Cadillac cast its own motors? If not, who does?

5—Does the Cadillac have a magneto?

6—Who was the first company to use a starter?

Washington, N. J. H. R. BROWN.

—1—A recent statement by the Cadillac company shows they have built experimental six motors in various forms and have tested them in every way known to them.

2—The first car in America to equip with a two-speed rear axle is the Austin. This car and the Cadillac are the only cars so equipped at present.

3 and 4—All of the Cadillac parts except the equipment such as rims, lamps and wheels are either made and assembled by the Cadillac company or partly made or assembled elsewhere. The lamps are of Gray & Davis make, the wheels, Schwartz, and the rims, Kelsey-Booth. The motors are made entirely in the Cadillac shops.

5—No. The Delco combined lighting, starting and ignition system is used.

6—The Winton company is given credit for having been the first to regularly equip with a starter, although experimental models were used before this.

Lead Advantageous in Refining Steel

Uniformity of Heat Permits of Same Degree of Hardening at All Spots, Preventing Internal Strains

"Lead, free from sulphur and other chemical impurities, is of great advantage in hardening steel on account of the uniformity of its heat"—A. L. Riker, Chief Engineer of the Locomobile Co. of America

LEAD as used for hardening and heat treating baths, or what is commercially known as refined lead, is free from sulphur and otherwise chemically pure. This is an absolute requirement for, if the lead contained even a small percentage of sulphur it would result in the pitting of the work on account of the affinity of sulphur for iron.

The use of the lead bath for hardening is, on account of the uniformity of heat, of great advantage in hardening according to those who have employed it, because it enables the work to be hardened all over and not in spots; thereby preventing strains in the metal, and by preventing air from coming in contact with the heated pieces, prevents oxidation, which is a common fault with open fire methods.

The lead bath is of marked advantage for the hardening and tempering of small work, and is of special advantage in hardening the ends of tools, etc., where heating the whole piece would be unnecessary and would even in some instances, spoil the work.

From the standpoint of rapidity the oil method is claimed by its users to be three times as efficient as the open fire, but all pieces except small work should be pre-heated before being placed in the lead bath, otherwise rapid heating would tend to cause the metal to crack.

For Steel Above .7 Per Cent. Carbon

The general range of tool steel contains from .7 per cent. to 1.4 per cent. carbon. The lower figure is used for the easily-weldable steels such as are used in drop forging dies, etc. and the upper figure represents the other extreme such as steels for razors and other hard cutting tools. In referring to the heat treatment it will be understood that the high carbon steels are meant, that is, steels which are sufficiently high in carbon composition not to require the addition of any carbon in hardening them and which are therefore known as self-hardening steels.

When a steel of this class is heated to a high temperature and then plunged into a cooling bath, a change in the internal structure of the metal takes place. The steel as a result becomes hard and brittle. The temperature to which it is necessary to heat the steel to get this hardening effect is what is known as the critical temperature of the metal. At or above this temperature an internal change takes place in that the carbon and iron contents of the steel enter into a new relationship with one another and a hard constitutent known as austenite is formed. Austenite is a solid solution of carbon in iron and in it the carbon may be present up to 2 per cent. The nearer the carbon approaches the 2 per cent. limit, the harder the austenite and the harder the steel. When the steel is cooled rapidly, the austenite for all practical purposes is considered to remain unchanged and thus to give the steel its required hardness.

If the steel is cooled slowly the austenite disappears and in its place there results a mechanical mixture of pure iron and a chemical compound of iron and carbon. The result of this disappearance of austenite is a soft steel.

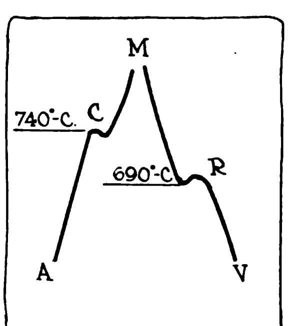
The hardness of steel is thus seen to depend on two factors, first on the amount of carbon there is in it and second upon the rapidity with which it is cooled which determines the amount of austenite actually left unchanged in the steel. If cooling could be instantaneous, then the theoretical result of an unchanged amount of austenite after cooling would be true and the nearer the approach to the instantaneous cooling the less the change in the austenite.

Temperature Rises Regularly

When raw steel is heated uniformly, that is when the amount of heat added is uniform per unit of time the increase in temperature of the steel proceeds regularly up to a certain point in the manner shown in the accompanying illustration. The regular rise in temperature takes place from A to C. At the latter point an absorption of heat takes place which causes a slight fall off in the temperature of the metal. This point which is at about 740 degrees Centigrade with a .9 per cent. carbon steel is known as the calescence point. After this point is passed if the heat is still applied at the same rate the rise in the temperature again becomes steady although not as rapid as at first. The absorption of heat is due to the energy required in forming the austenite. It is therefore necessary in hardening steel to heat it above the point of calescence.

If the steel is allowed to cool regularly, by the abstraction of definite amounts of heat per unit of time the heat will drop uniformly as shown in the curve from M to R and then at a temperature of about 690 degrees Centigrade, a retardation of cooling will be noted, in fact a slight rise in temperature will occur. This point which is known as the recalescence point, is where internal changes which result in the giving out of heat take place. From R to V on the curve the cooling is again uniform.

Should the steel be heated above the calescence point and



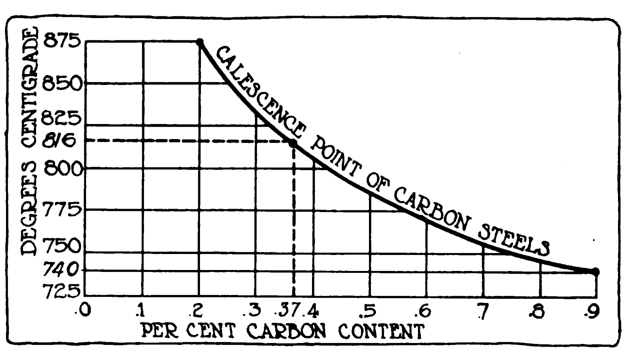


Fig. 1—Left—Rise and fall of temperature of steel heated uniformly. C, calescence point; R, recalescence point. Fig. 2—Right—Approximate curve of calescence points of carbon steels

then the temperature allowed to drop until it had passed below the recalescence point, the characteristics of the steel would not be found to have varied to any extent. The change that takes place at calescence is reversed at the recalescence. If, on the other hand, the steel is cooled suddenly before the temperature has dropped below the point of recalescence, the changes which took place at the point of calescence, notably that of the formation of the austenite, are rendered permanent as far as all practical considerations obtain.

Practical Hardening of Steel

When steel is hardened in a practical way it is necessary to subject it to a temperature somewhat above the calescence point for safety's sake in order that the operator can be sure that the internal changes he desires have taken place. The point of calescence varies with steels of different carbon content and an approximate curve of this carbon variation in steels of from .2 to .9 per cent. carbon is shown in Fig. 2.

After the heating has been completed it must be remembered that the plunge has to be made quickly before the temperature drops below that of recalescence. It must also be remembered that the hardness of the steel will depend on the quickness with which the temperature is brought from above to below the recalescence point. Rapidity is necessary to obtain great hardness and uniformity in cooling rate is necessary to obtain uniformity in hardness.

The rapidity and uniformity of cooling are affected by the following properties of the bath: conductivity, specific heat, density, latent heat of volatization, all of which factors should be high and boiling point, viscosity and initial temperature which should be low. It must be remembered, however that cooling cannot be done too rapidly in many cases on account of the dangers of cracking.

The tempering process which follows the hardening has two primary purposes, the first is to reduce the hardness to the desired point and the second is to remove the internal strains which may have been produced by the sudden chilling of the metal in the hardening work. The tempering process consists of re-heating and then re-cooling but to what temperature the heating is done and at what rate the cooling takes place in securing the desired reduction of austenite depends on the nature of the work and the ideas of the operator.

Lead Best in Hardening

It is in the hardening work that lead meets its best use. It brings the metal above the calescent point quickly, thus saving time. The perfect exclusion of air from the article to be hardened so that no oxidation or burning out of surface carbon can occur is another advantage. The lead bath gives an even heat throughout the article and it is comparatively simple to keep the temperature regulated. The National Lead Co. is making a special lead for this work and guarantees its purity to be 99.9947 per cent. This purity is of the utmost importance or the value of the lead bath is destroyed.

The following is given by the above mentioned company as a typical analysis of refined lead for hardening:

	Per Cent.		Per Cent.
Silver	.0006	Manganese	None
Antimony	.0030	Arsenic	Trace
Tin	None	Sulphur	None
Bismuth	Trace	Phosphorus	None
Copper	.0002		
Cadmium	None	Total impurities	.0053
Iron	.0015	Lead (by difference)	99.9947
Zinc	None		
Nickel and Cobalt	None		100.0000

Good Roads in Egypt Make Demand for Cars

NEW YORK CITY, Aug. 15—The possibilities of Egypt as a motor car market are well set forth in the following extract taken from the *Egyptian Mail* of June 26, 1914:

"Two years ago Egypt was almost as roadless as Albania is today. There were a few roads around Cairo, and you could reach the Pyramids on a first-class macadam road. There were a few other roads to Heliopolis, Zeitoun, and another to Ameadi. Alexandria was worse off.

"It was surprising that motor cars should have any vogue under such conditions, yet there was a good demand for them in Cairo and there always were plenty to be seen in Alexandria.

Last 2 Years' Progress

"The last 2 years have witnessed remarkable changes in Egypt in many respects, but in none more than in the matter of roads. Lord Kitchener saw the need for better roads and was not 6 months in the country before work was being pushed on the road between Cairo and Alexandria. A government department was created exclusively to look after roads, and today there are some hundreds of kilometers of good roads in the Nile delta, along which it is possible to motor in comfort. Every year this road department has been increasing the scope of its activities.

Hard Earth Roads

"The roads are not macadamized, except occasionally in the proximity of big towns, but are made of earth rolled down to form a hard surface. It is not a method calculated to stand heavy traffic, but they are good for speeds from 30 to 40 miles per hour. In one place along the Nile a charming macadamized road has been built, and it is now possible to motor many miles on a macadamized road along the banks of the picturesque Mahmudia Canal.

"This country-wide road activity means an increase in demand for motors, and for a market with widely varying requirements. Cairo and Alexandria will continue to demand cars for town work pure and simple. Most of the best makes of English and French cars are used for this purpose, though it is rare to see anything over 20 horsepower. With native Egyptians the limousine is the most popular type, as it suits the harem better than any other. Open cars preferred range from 12 to 16 horsepower and for this type the demand is greatest. A car of this nature can be used in Cairo and Alexandria as well as anywhere in the provinces. This, too, is the kind of car purchased by the government.

"Then, again, there is a great demand for the small two-seater, the number of bachelors in Egypt being proportionately high amongst the European communities. This class prefer the two-seater.

Want Light Touring Cars

"The motor manufacturer who wishes to push his cars in this country should turn out a strong and light touring car ranging from 12 to 20 horsepower. A car of this kind suitable for the English market with very little alteration, such as the lengthening of springs, a specially large and airy hood and strung rather higher from the ground than an English touring model should do very well."

The Engineering Digest

How to Get a Uniform Light from Lamps with Parabolic Reflectors by Suitable Adjustments

MANUFACTURERS of headlights are expected to provide a combination of light source and reflector which can be adjusted to give a suitable illumination. In some cases a lens forms part of the equipment, but it makes the lamp heavier and costlier and for ordinary traveling purposes the reflector alone will concentrate the light sufficiently without getting undesirable effects in the bargain. The adjustment left to the purchaser of the headlight should be nothing more than moving the light source a little in or out with relation to the focus of the reflector. And in practice nothing more is usually expected of him. But it happens that the best obtainable adjustment, in a case of a poorly designed lamp, is not a satisfactory adjustment, giving rings, streaks or spots of stronger and weaker illumination, trying on the eyes and interfering with sharp discernment of objects. It is the art of the lamp designer to avoid these effects, while getting a maximum of illumination where it is wanted with a minimum of encumbrance and cost.

The principles governing this phase of the headlight subject are explained in a simple manner by Robida and make it clear why, for example, a lamp of moderate power and correctly constructed may give more comfort for night-driving than a more powerful lamp less scientifically designed.

It is the property of a parabolic mirror to reflect all light rays coming from the focus in a direction parallel with its axis, so that all these light rays form a solid cylinder. Thrown upon a screen or wall at right angles with the axis these rays consequently illuminate a circle of the same diameter as the face of the reflector.

When the light source is moved forward, as from the focus F to the point E in Fig. 1, the reflected rays will converge toward a certain point in the axis, and at this point E′ there will thus be produced an image of the light source. If not intercepted on an opaque substance at this point, they cross and continue in space, forming a light cone which appears to come from the location of E′.

In reality it is not strictly accurate that all the rays converge to exactly the same point in the axis, but they do converge to a very short line, forming part of the axis, and this small inaccuracy can be neglected, as it remains true that a lamp with its light source in front of the focus causes the rays to converge almost to a point where an image almost as brilliant as the light source itself is produced, and every grain of dust, every insect and every globule of vapor, in the case of a mist, which passes by this point is illuminated in a violent and disconcerting manner. If the point of convergence is far enough ahead — the light source being close to the focus, yet ahead of it—the image of the light may even be reflected back into the eyes of the driver from any brilliant object, such as some part of an automobile coming in the opposite direction, and the glare may blind him.

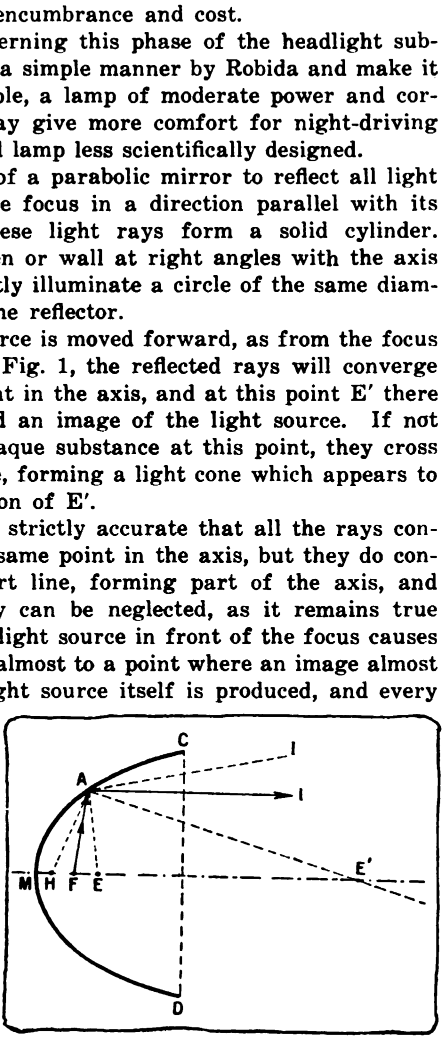

Fig. 1—Showing theory of parabolic reflector

The first principle for the design of a headlight, in which only the action of a reflector is depended upon for the desired light effects, is therefore that the light sources must be placed behind the focus of the parabola, as at H in Fig. 1. The reflected rays will then always diverge from the axis, like the line AI, being the reflection of the ray HA, and no image of the light source will be formed in front of the lamp.

The light sources which can be used in practice are not concentrated at a mathematical point, however, and for this reason some complications arise. In fact the filaments in incandescent lamps, whether they are shaped as coils, spirals or in zig-zag formation, have rather large dimensions, compared with the distance of the parabolic focus from the nearest point of the mirror. Fig. 2 illustrates the irregularities arising from this cause.

KH is the filament which is placed slightly behind the focus F. From each point of the filament rays issue which are reflected in the form of a cone, and the cones formed from points near K are more irregular than those formed from points nearer the axis of the mirror. In combination all the cones formed from individual points of the light source constitute a cone more irregular than any one of them, and the angle of divergence of this light cone issuing from the lamp as a whole depends upon the two factors: (1) the divergence of each elementary cone and (2) the divergence of the elementary cones among themselves. The latter element depends solely upon the size and shape of the light source, and cannot therefore be reduced below a certain practical minimum in each case.

Attempting a Searchlight Effect

If now it is considered desirable to obtain a light cone which does not spread much and, with this end in view, one makes arrangement to have the divergence of the elementary cones smaller than the divergence which can be realized for the light cone in its totality—as may be done by placing the light source very close to the focus, behind it—the elementary cones become separated at a certain distance ahead where the boundary lines of the slightly divergent elementary cones cross the more divergent boundary lines of the cones sent out from those points of the light source which are removed from the axis. If all the light is caught on a white wall there is in fact noticed upon the latter a large distorted image of the light source represented in the variations of light values on different portions of the wall, and in practice this discontinuity of the illumination at a certain distance ahead of the car shortens the actual reach of the headlight by creating confusion.

To avoid this effect it is necessary to place the light source so far back of the focus that the divergence of the light from any one point covers the divergence due to distance from the axis of some portions of the light source. The method of proceeding to obtain a suitable adjustment of a lamp which is designed well enough to admit of such an adjustment being made (that is, in which the dimensions of the light source and those of the reflector, as well as the angle of the parabola are so selected as to admit of the desired results), may be outlined as follows:

It is best to light the headlight in the daytime so as to avoid fatiguing the eyes. The lamp is then moved forward or backward until by looking into the reflector at a distance of several yards the whole face of it seems to be one mass of light. The filament is then very close to the focus, and no image of the light source is visible. If the filament is moved from this position well toward the back of the reflector, an actual image is soon seen to form far back of the mirror, apparently, and the latter no longer seems uniformly lighted.

Method of Adjusting

With the filament close to the focus the light is now projected upon a white wall. A more or less irregular illuminated spot is seen. The science of lamp makers consists largely in making the irregularities in the distribution of light over this area as inconspicuous as possible by the means before mentioned. Still they will be noticed to some degree with the adjustment as stated.

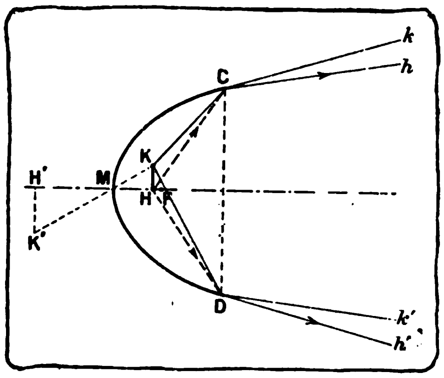

Fig. 2—Showing conflict of light rays from filament HK of relatively large dimensions. H' K' its magnified image.

But if the filament is moved backward a little—not as far back as to cause an image of the filament to be seen apparently at a distance behind the mirror, as before referred to—the irregularities on the wall disappear gradually and the light becomes more and more uniformly distributed. At first the illuminated area barely increases in size by this adjustment, because the elementary light cones are less divergent individually than in their relations to one another, but when the filament reaches a certain point in this backward movement of it, the divergence of the rays from each point in the light source finally becomes as great as the divergence due to the size of the filament, and from that moment, if the backward movement were continued the illuminated spot on the wall would grow rapidly in area while the light value at any one point of it would diminish. At this position the adjustment should therefore be stopped.

This is not the mode of adjustment giving the greatest penetration along the axis of the reflector, as the light cone is made divergent on purpose, but it gives the greatest regularity of the light throughout the area which receives light at all. And this is the preferable system, because it permits one to see objects at both sides of the road, puts less strain upon the automatic adjustment of the eyes to different degrees of illumination, enables one to discover more readily a vehicle coming out from a side road and makes it easier to pass by vehicles coming from the opposite direction.

If an adjustment such as described leads to a spread of the light which is really too great it is usually better to choose a smaller incandescent filament than to concentrate the light by a different adjustment. Both methods will give a less divergent cone of light, but the weaker lamp will give more acceptable results if the light from it is more uniform by reason of being more suitable for the shape and dimensions of the reflector.—From *Omnia*, July 23. (Author neglects the effect of using two headlights.—ED.)

New Type of Automatic Carbureter Easily Adjusted

IT MAY be doubtful if the carbureter represented in three sectional views in Fig. 3 is fully equal in its present form—especially with regard to its responsiveness to acceleration and retardation and in fuel economy—to the many excellent carbureters produced lately in all of the four principal countries of the automobile industry, Germany, France, England and the United States, but it is different from any other and may suggest new ideas along the line of progress.

The sections are taken along the planes AA, BB and CC. Owing to the peculiar, spiral shape of the air channel, the device has been called the *Turbinen-Vergaser*, or turbine carbureter. This shape and the lateral entrance for the additional air are supposed to contribute to the formation of a uniform gas mixture. The level of the fuel, which is indicated by a dotted line, is only very slightly below the mouth of the two jets *b* and *f*, and these are at the same level as the lower edge of the throttle valve. The small jet *f* is closed by means of a ball *a* unless the throttle is almost closed, when a small pin *c* upon the edge of the valve pushes the ball to one side and releases the flow of fuel through *f*. The air needed for starting and still-running is adduced through the opening *m*. When the throttle is opened more, *f* is obstructed by the ball going back into the position in which it is held more and more accurately over the mouth of *f*, until the pin upon the valve finally is withdrawn completely and allows the ball to shut *f* entirely. "With increasing motor speed the main jet *b* now begins at once to work," says the German describer at this point, falling into the common error of neglecting to state how the motor reaches the increased speed by the action of the throttle valve upon the carbureter. It is not plain that the acceleration is in fact accomplished by any other means than ceasing to obstruct the air passage and relying upon the motor speed to be kept up by the momentum of the flywheel and of the vehicle until the larger flow of air has taken effect upon the main jet—which is the method now largely discarded as precarious in other modern carbureters, giving fitful and unreliable accelerations. The describer says however that there is created at once "by the increasing motor speed" a correspondingly increased suction by which the hinged cover *h*, which is held down over the air port by means of a weight which can be secured at different points upon a lever arm, is raised and admits a current of air to enter transversely of the fuel current from jet *b*. The system of an adjustable weight to hold the airhole cover down lends itself to a facile regulation of the gas mixture

The sectional view along the plane BB, to the right in Fig. 3, shows the adjustment screws by which the amount of fuel passing through the two jets may be regulated. The channels through the jets are large, so as to be adaptable to different motor sizes by this adjustment only. Jet *b* has a lateral bore to the air current.—*Der Motorwagen*, July 20.

New Rotary Motor Has Axial Cylinders

Macomber Air-Cooled Rotary Motor Simple and Free from Vibration—Manifold Used as Muffler—Built for Cyclecars and Large Cars

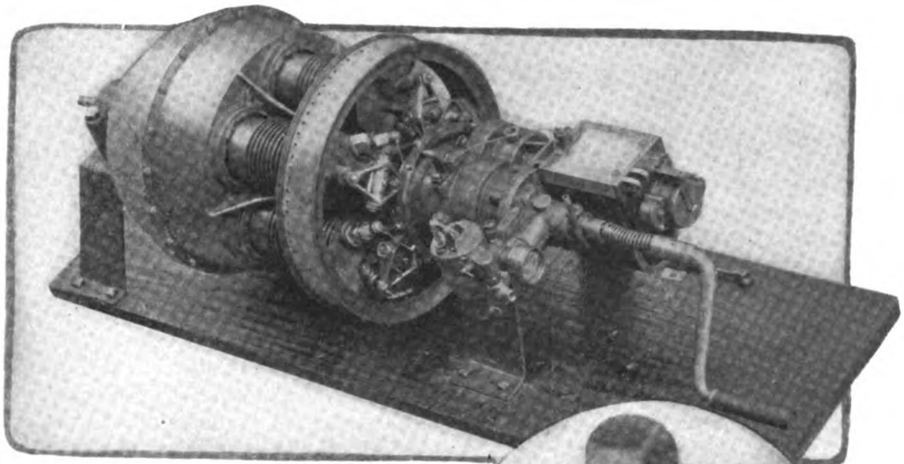

Fig. 2—Macomber motor, showing arrangement of cylinders and valve mechanism. Note ring type, exhaust manifold with holes to expel the burnt gases

Fig. 3—The cyclecar motor

CONOMY, simplicity and freedom from vibration are the salient features of a new air-cooled, rotary motor, Figs. 1, 2 and 3, manufactured by the Macomber Motors Co., Los Angeles, Cal. This motor differs from the ordinary construction in that it has its cylinders arranged parallel to the axis of rotation instead of radially. It is built in five and six-cylinder sizes, the former being an 11-horsepower design for cyclecars and the latter a 50-horsepower machine for larger cars. The two designs are practically identical except in size and, therefore, only the smaller one will be described in detail.

Referring to Fig. 1, it will be noted that the part of the mechanism that remains stationary is blacked in. No crankshaft is employed, but the connecting-rods are attached to a plate that is set at an angle of about 25 degrees to the axis of the crankshaft. The connecting-rods are fastened to this plate by means of ball and socket joints and similar joints connect them to the pistons.

Reciprocation of the pistons is accomplished by the rotation of this plate. When the motor is running this plate is carried around with the cylinders and any given point on it moves the length of the stroke in one-half a revolution.

Overhead Valves Employed

Overhead valves are used, the intake valves being on the inside and taking the charge from a centrally located manifold. The exhaust gases pass directly from the valves to a circular exhaust header, Fig. 2, the outer circumference of which has a series of small holes from which the gas makes its way to the atmosphere.

A single rocker serves to operate the intake and exhaust valves to each cylinder; this is distinctly shown in Fig. 2. It will also be noted that the rocker arms are a heavy yoked construction.

A camshaft is not used, the valves being opened and closed by the movement of the inner ends of the rocker arms in a cam-like groove. The rocker ends are provided with rollers to reduce wear. Rocking one of the arms in one direction opens the intake valve and in the other the exhaust valve.

The starting crank is attached to the valve end of the motor. The carbureter is situated at one side and the magneto at the other.

The oiling is by a combination splash and circulating system. Gravity carries the oil from an automatic oiler on

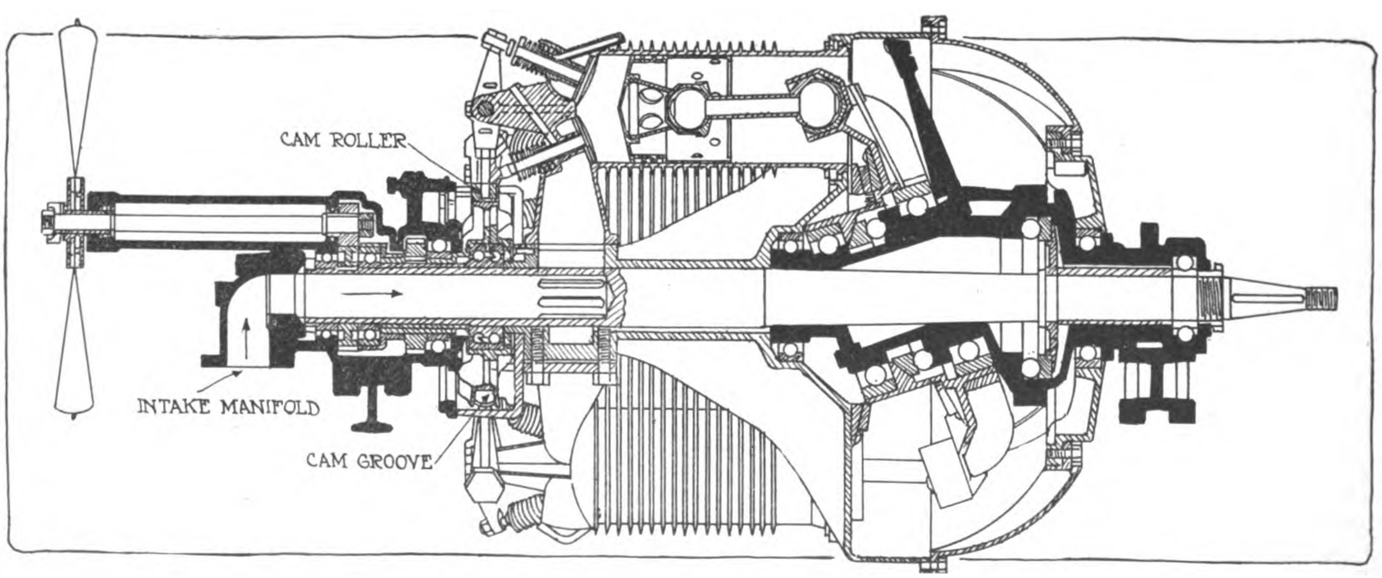

Fig. 1—The black portion indicates the stationary part of the mechanism. The intake is in the center

the outside of the motor to the center and centrifugal force throws it around the interior.

The large motor has six cylinders, 4.25 by 5.5 inches, and has a maximum speed of 1,500 revolutions per minute. The valves have a diameter of 2 1-16 inch and a lift of 5-16, and are made of nickel steel. The valve timing is as follows: Intake opens 10 degrees after upper dead center and closes 20 degrees after the end of the stroke; exhaust valve opens 45 degrees before lower dead center and closes 5 degrees after upper dead center.

On the 11-horsepower motor the bore is 2.375 inches and the stroke 3 inches. The diameter over all is 12 inches, and the length 24 inches.

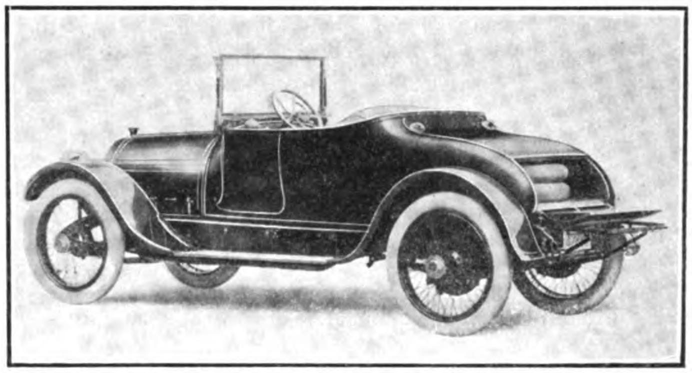
It is stated that these motors are remarkably free from vibration and that the economy is high, the smaller motor being capable of driving a machine over 60 miles on a gallon of gasoline, while the larger one will do 30.

Worthy of special note is the fact that while the ordinary motor with radial cylinders suffers from over-lubrication due to the oil being forced up into the combustion chamber by centrifugal force, this motor by the parallel arrangement of its cylinders has no such difficulty.

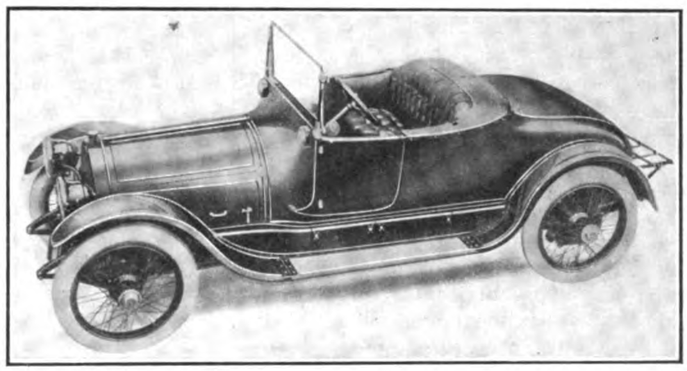
1915 Stevens Runabout Has Disappearing Top

New Cars Appear in One Model—Slight Power Increase—Cars Characterized by Graceful Bodies—Spare Tires Concealed on Runabout

STEVENS-DURYEA cars for 1915 follow very closely the general lines of the present product, although designated by only one model number, there are really two chassis, and in both of these there has been an increase of 1-16 inch in bore of the engine, so that the engine on the roadster chassis is now 4 3-8 by 5 1-2, and that on the touring chassis is 4 7-16 by 5 1-2. The roadster wheelbase is 131 inches and the touring wheelbase 138 inches, which is the same as that of the 1914 product. In other respects the chassis are the same as that of the earlier models, except that left drive is employed instead of the right drive, and that electric starting is fitted as stock equipment. The feature of the new line is a new roadster, which is arranged so that the top disappears completely inside of the body. The neat, attractive appearance resulting may be seen in the lower illustration at the right of the page.



Three-quarter rear view of new Stevens-Duryea runabout with disappearing top and compartment at the rear for spare tires



View of new Stevens runabout showing the method of covering the opening into which the top disappears

Disappearing Top

Continuous streamlines, characteristic of Stevens-Duryea bodies, have been carried out in this new type, the deck sloping gracefully from the back of the seat and rounded at the rear. The gasoline tank is entirely inclosed, and provision also is made for carrying two tires mounted on rims, or one wire wheel mounted and extra tire, under the deck, completely inclosed and out of view. The top is supported by mechanical means by neat but rigid joints, which cause it always to follow a certain path in folding into and being withdrawn from the body; it is self-supporting and when up requires no braces of any kind, being rigidly fastened to the windshield supports in the same manner as in the Stevens-Duryea touring cars. When the top is folded the concealing compartment is completely covered by the upholstery. The opening is also covered by the upholstery when the top is in use, thus making a neat, finished appearance, in either position, as well as affording full protection to the top from dust and dirt when concealed.

New Auxiliary Seat

A new type of auxiliary seat is employed in the seven-passenger touring cars. Each seat has one upholstered arm on the inner side, the upholstered arm rail providing a rest on the outer side. The construction allows for folding backwards and sidewise against the side of the tonneau, or when in this position can be tipped forward in front of the entrance, thus removing these extra seats entirely out of the way of passengers occupying the rear seat and obscuring them from view of those outside of the car.

In addition to the complete line of open and inclosed cars as marketed by the Stevens-Duryea company during the season of 1914, the company is offering a seven-passenger landaulet, built on 139-inch wheelbase chassis.

In the electric ignition system the Stevens-Duryea company has retained the two independent Bosch high-tension magneto and battery systems of ignition with synchronous coil, high-tension timer distributer and instrument-board switch. Two sets of spark plugs are furnished which, with the independent systems of ignition, eliminate chances of trouble in this connection.

Unit Power Plant Continued

Stevens-Duryea unit power plant, suspended at three points, continues to be a feature of these cars as it has been for many years. The disk clutch, progressive three-speed gearset, floating axle and 37 by 4 1-2-inch tires are continued.

M. A. M. Has Efficient Traffic Dept.

Audits and Corrects Freight Bills of Members, Saving Material Sums—Consults with Shippers and Railroad Representatives

By Alfred P. Sloan, Jr.,

Secretary and Assistant Manager

A FEW years ago, realizing the large amount of unnecessary drain upon manufacturers—a drain that was going into the coffers of railroads, not because of dishonest intent, but rather due to existing conditions—a traffic service was inaugurated by the Motor and Accessory Manufacturers Assn., which numbers in its membership 262 of the leading American makers of automobile parts and accessories and represents a combined capital of $440,000,000. Since that time this department has been developed to a really remarkable degree of efficiency, and through its co-operative workings thousands of dollars have been saved for members of the association who have made use of this department. Indeed, many of the members have found that the amount of refunds from railroads on incorrect freight bills, after having been audited and claims registered by the Traffic Department, have more than paid for the annual fee for membership in the association. When one stops to consider that one member recovered the sum of $870.72 on his claims of a few months, it will be seen at once that the above statement is not exaggeration.

Auditing Freight Bills

The matter of auditing freight bills, while an essential one, is only one of the important branches of the work of the Traffic Department. Any member of the association may send all of his freight bills to the department regardless of the number of bills or the amounts involved, and each separate shipment will be carefully checked by the experts employed by the department to ascertain if the road or steamboat line has made an overcharge. The law requires that the correct published rate be applied on all shipments even though railroads have by error quoted other figures. Naturally in the course of the really intricate matter of routing shipments from point to point over several different roads, the human equation enters into the case. No matter how experienced the one in charge of the shipping department may be, his knowledge of freight rates is bound to be limited and certainly the knowledge obtained in a cooperative way by the Traffic Department through having handled to date more than 100,000 freight bills, dealing with every section of the country, is superior to any one man's knowledge.

Some idea of the scope of the work of this department and how it is appreciated by members is made evident by a few comparative statistics. The first year it was in operation, 1911-1912, there were forty-three members who made use of the department. During the fiscal year July 1st, 1913, to June 30, 1914, the department was used by 136 members a total of 803 times. During that period 51,690 freight bills were audited. Out of the number of freight bills audited a very material percentage were found in error and warranting traffic claims being entered. Incidentally, it may be mentioned that the Traffic Department enters these claims with the railroads and upon collection turns the amount over to the members. Recognition of the value of Traffic Department is shown by the fact that in the year 1913 there was an increase of more than 60 per cent. over 1912 in the number of times the department was used by members, and the number of claims was exactly doubled.

Checking results from a dollars-and-cents standpoint, the total amount of claims entered the past year was $2,973.13, and with thirty-three members involved meant an average refund of $90, just $40 more than the annual membership fee. Of the above-mentioned sum of $2,973.13 for claims entered up to the close of the fiscal year, $2,230.82 of this amount had been paid, which figures demonstrate the fact that claims entered by the Traffic Department are not mere idle claims, but result in material return.

The Traffic Department of the Motor and Accessory Manufacturers is under the direct supervision of J. S. Marvin, who is general Traffic Manager of the National Automobile Chamber of Commerce and is unquestionably one of the best informed men in his line in the country.

Consulting on Shippers' Rights

But aside from the auditing of freight bills the most important feature of the department of far-reaching benefit, one which is not explainable in dollars and cents, is the matter of consultation on shippers' rights in traffic matters of any character. If a member wishes to be advised how his particular article or commodity should be packed, described or billed to secure the benefit of the lowest transportation charge, he can secure information resulting in great saving and this saving is impossible to estimate. Such entries may result in the department securing a reclassification of the article in event that there appears to be an opportunity, and here again an immense saving for the manufacturer results. The extent of this branch of the work is indicated by the fact that during the past year 3,500 bulletins dealing with fifty-two subjects relating to the Traffic Department have been issued to members, while the previous year nearly 6,000 bulletins dealt with sixty-eight subjects. These related to specific subjects or points involved in shipping, and although it has been shown in a general way from the start how members may use the department, it has taken time for members to realize the cooperative service that can be rendered. Bulletins show the actual occurrences, rulings and points decided.

In Touch with Railroads

At all the meetings of the various railroad rate-making committees the Traffic Department is represented and is advised in advance of the subjects to be considered at these meetings. To illustrate: among the items recently considered by railroads regarding which the department has been able to render assistance, are automobile engine and gear parts, radiators, speed indicators and attachments, bodies, ball bearings, horns, tires, lubricators, grease cups, mufflers, camshafts, etc. If ratings or shipping requirements are to be taken up, the manufacturers of the machines or parts involved can be informed and their interests represented. Changes made in the published rate tariffs and classifications which affect transportation charges are kept before the membership so that the shipping departments of the factories may take advantage of the most favorable rates.

Ruetschi Gearset Keeps Perpetual Mesh

Employs Combination of Planetary and Sliding Principles—Impossible To Clash Gears

A THREE-SPEED gearbox designed to furnish non-clashing changes to any speed has been brought out by the Motor Engineering Co., Cleveland, O. It secures the direct driving features through a combination of the planetary and sliding gearset principles. The advantages claimed for this system of gearing, which is the invention of Arnold Ruetschi, of Cleveland, is that it is impossible to clash the gears when changing from one speed to another and no gear changing is necessary on a hill because the gear can be selected before it is needed and when it is required a movement of the foot in depressing or releasing the clutch pedal throws the desired gear into operation.

Has Two Principal Elements

A sectional view of the gearbox is given in the accompanying illustration. As the gearbox stands it is in neutral position, and as will be seen is composed of two principal elements; namely, the gearbox proper which is bolted to the engine crankcase as in any unit system, and the rotating housing which carries two countershafts one of which is shown in the sectional illustration. In the drawing the exterior housing is denoted by A, the rotating housing by D and the countershaft C.

When in high speed the rotating housing B rotates solidly with the entire drive giving the direct high speed, but in first and second speeds and reverse this movable housing is stationary. The method of locking the housing against revolving is by means of the clutch D. When this engages with the solid anchored frame A, it is incapable of revolving. On the other hand, when the clutch is engaged with the motor member it is rotated by the motor and revolves as a unit.

Casing Revolves as Unit

In high, low and reverse speeds the gear clutch E is in mesh with the internal gear F, and in intermediate speed the gear clutch E is in mesh with the internal gear G. High speed may be also attained with the gear clutch E in mesh with G because the entire revolving casing is moving as a unit and the position of E is immaterial.

Tracing the drive through the gearbox, it will be seen that on high speed it is transmitted to the clutch member D, which is free of the anchored member A, passing through the solid casing B and thence to the rear axle. That is, the entire gearbox moves as a solid part of the shaft and there is no motion in the gears and countershafts.

When in intermediate speed the drive passes through the main shaft H and thence by means of the shaft clutch E to the gear G. This in turn meshes with the gear J on the countershaft C, giving a planetary motion to the gear on the countershaft which follows around carrying with it the rotating housing which transmits the drive.

During this time the clutch D has been moved backward into engagement with the stationary clutch on the housing A which brings the rotating gear case to rest. The low speed is then secured through the two countershafts, C. After bringing the gearcase to rest the drive is no longer planetary but becomes the same as in the sliding gear transmission. This gives only a straight torsion on the driven shaft.

To change from intermediate to high speed the clutch pedal which controls the clutch D is released and the clutch is brought into engagement with the flywheel member, thus locking the whole unit together, giving high speed.

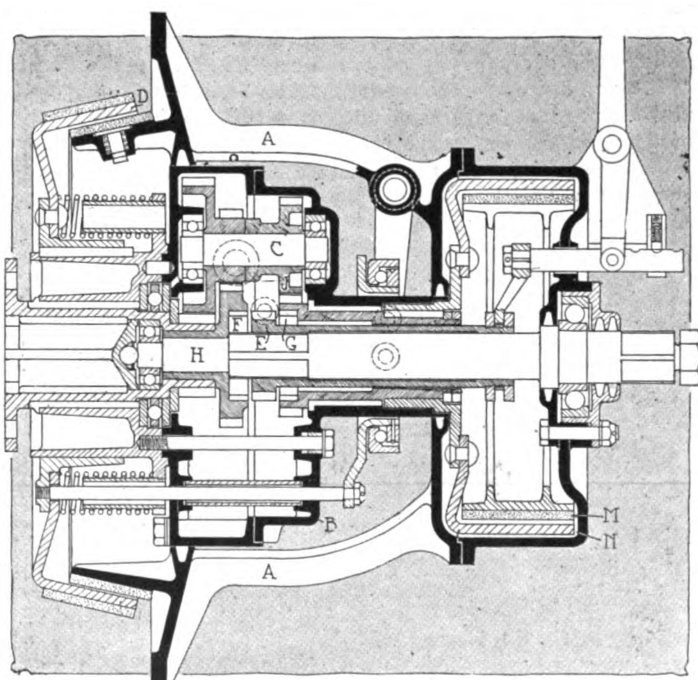
Reverse is obtained by having clutch D in neutral position and applying the brake M on the drum N which brings to rest the idler gear G. The countershafts C then revolve backwards with a planetary motion, carrying the idler gear F along with them at a reduction given by the gear ratio.

When traveling along on high speed if it is desired to be ready to shift into second it is only necessary to mesh the gear E with G and leave it in that position until ready to make the change. Then, no matter at what speed the car is traveling, the change can be made by simply depressing the clutch pedal which will lock the rotative housing, bringing it gradually to rest with a smooth cone clutch action. As soon as the housing has become secured owing to the pressure on the clutch the second speed comes into the action. In this manner there is no meshing of revolving gears as the gears are set before the change is made. The same principle is involved in using the low speed except that the gear E is meshed with F instead of G.

Ball Bearings Used

Entire gearbox is carried on ball bearings and weighs for a 12-18 horsepower unit complete with pedals, clutches, levers and brake, 50 pounds. The gear ratio supplied on low speed to the gearbox alone is 4 to 1. On the second speed 2.25 to 1, and on direct drive with all gears locked it is 1 to 1. The reverse ratio is 3.8 to 1. The gearbox is applicable to any size of car and is claimed to be of particular advantage to trucks where a large amount of shifting can be done without clashing the gears.

By the liberal use of aluminum the gearcase can be made of exceptionally light construction. It is exceedingly flexible and if desired reverse could be thrown in while the car is traveling ahead at high speed.



Section through the Ruetschi gearbox. The drive is taken either through the clutch at D, which in turn rotates the casing B and transmits the drive solidly to the rear axle, or the drive is taken through the gears F, E or G with the clutch D held firmly by engagement wtih the solid member A. The advantage claimed for this system of gearing is that it is impossible to clash the gears when changing from one speed to another and that no gear changing is necessary on a hill because the gear can be selected before it is needed and then brought into use by pressure on the clutch pedal

1915 Hupmobile Has Left Drive

Car Is Entirely Re-Designed—Wheelbase 13 Inches Longer—Motor Is Larger—Streamline Body

UNDER the name of Model K the Hupp Motor Car Co., of Detroit, Mich., has brought out an entirely re-designed car for the 1915 season. It is a larger and more powerful car than the Hupmobile of last year and there is hardly a feature throughout its construction that is unaltered.

Left Drive and Center Control

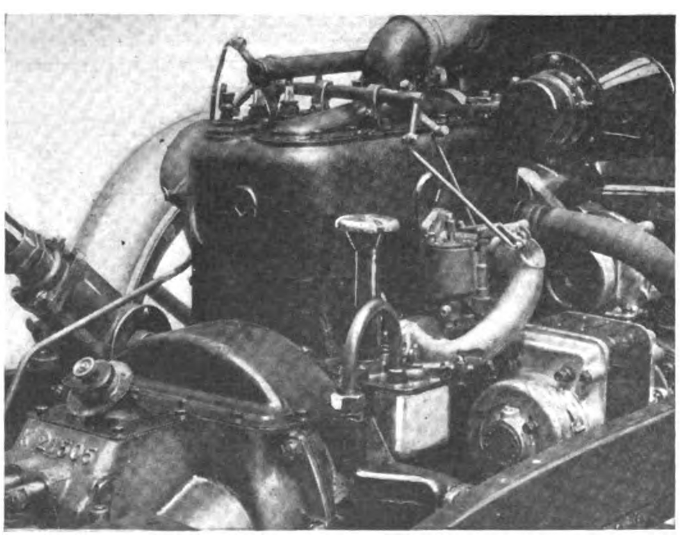
To take care of the larger power plant and bigger body the wheelbase has been changed from 106 inches to 119 inches, and in making this chassis change several features that were formerly peculiar to Hupp practice have been radically reconstructed. Left drive with center control is one of these innovations and another which marks a difference between the car of today and the previous ones of Hupp design is the use of semi-elliptic underslung rear springs in place of the former cross rear springs. In changing the suspension the entire framework of the chassis is new and this in turn has been the cause of alterations in the linkages, brakes and control members.

Some Hupmobile Refinements

Larger Body of Streamline Type	Horizontal Type Carbureter
Wheelbase Increased Thirteen Inches	Hexagonal Cell Radiator
Left Drive with Center Control	Motor Bore Increased 1-8-inch
Semi-Elliptic Springs in Rear	Automatic Spark Advance System
Single Unit Electrical System	Unusually Complete Equipment

Three-quarter front view of 1915 Hupmobile roadster

While many of the fundamental features of the motor design remain the same, the bore has been increased 1-8 inch. The water jackets are larger and the valve diameters have been increased. The connecting-rods are longer, all the bearings larger, with wider ports and an entire change in the manifold design. The carbureting system is also new in that it now preheats the air by means of exhaust heat. While the Zenith carbureter is still employed, it is now the horizontal type instead of the vertical and is now a 1.25-inch size in place of the 1-inch formerly used.



Right rear of Hupmobile motor, showing Westinghouse single unit lighting and starting equipment and also new Zenith carbureter. Note linkage over cylinders for flap air valve on carbureter

Single Unit Electrical System

The electrical equipment of the car has also been entirely re-designed. As in its predecessor, the new car employs the Westinghouse electric lighting and starting system, but instead of using the double unit system the cranking motor and the lighting generator are now combined into a single unit. Instead of using magneto ignition, an Atwater Kent distributer driven from a vertical shaft and supplied with automatic advance has been fitted. With the application of the new distributer many other exterior fittings of the motor have been altered. There is a new fan bracket which maintains a continuous tension on the fan belt by means of a coil spring.

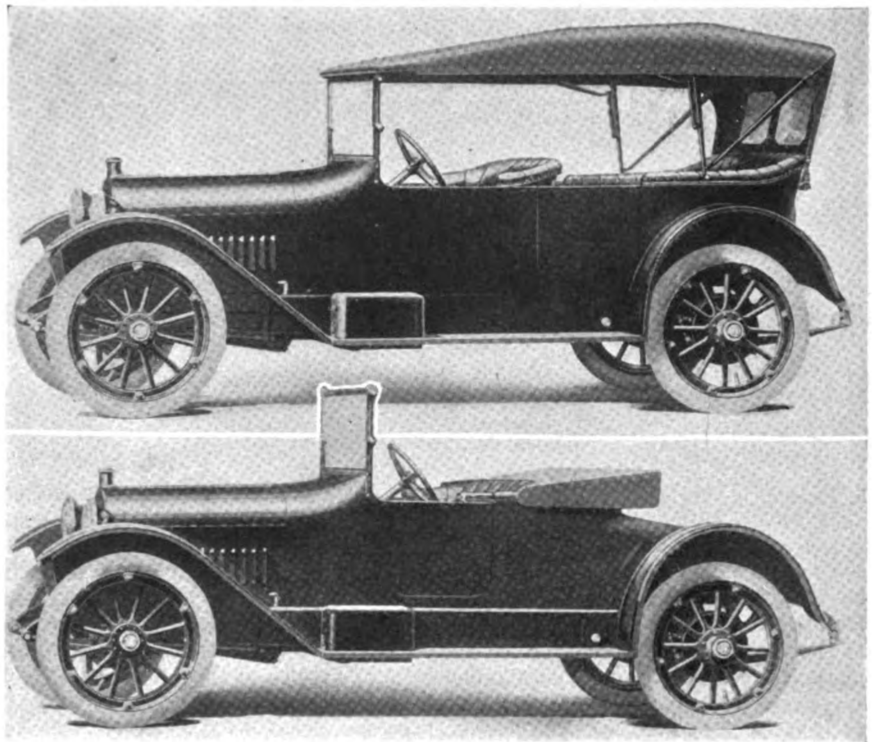
Gearbox Is More Accessible

In rearranging the motor, the drive of the camshaft has been moved from the rear to the forward end. The oil filler has been moved back to accommodate the new position of the carbureter and, while the oiling system itself has not been altered so far as the motor is concerned, it no longer takes care of the gearbox. The object has been to rearrange it so that heavier oil can be employed for a gear lubricant. Instead of the gearbox being a unit with the crankcase it is now bolted on separately, making a more accessible job as far as reaching the gears in the gearbox is concerned. Large cover plates are now placed over the gearbox and clutch housing and the oil filler opening projects through the floorboards of the car so that the driver may refill the gearbox without lifting these boards, but by merely picking up the cover of the floorboards.

The clutch is the same in principle as in the last model, but has been turned completely around, the purpose being to put the thrust drag on the gearbox rather than on the motor when slipping the clutch. The diameter of the clutch remains the same at 13 inches but the number of plates in the clutch has been increased by four. There are now thirteen. Just back of the clutch there is a new chassis frame member extending transversely, which acts as a stiffener and which carries the pedal shaft for the brakes and clutch.

Two Universals Instead of One

While the shaft system of drive is practically the same, there are now two universal joints, one at either end of the shaft, whereas in a former model there was but one. The rear universal which has been added is a cross type. The propeller shaft is now tubular and the lubricant from the forward universal is allowed to run back through the hollow shaft to the rear universal. There are now no radius rods or torque members, both the drive and torque being taken through the new springs.



Above—1915 Hupmobile touring car. Note absence of side lights. Note also one-man top and ventilating windshield. Lower—New Hupmobile roadster showing streamline design. Note underslung semi-elliptic rear springs

The entire rear axle is new. In former Hupp cars when it was desired to reach the differential it was necessary to remove the bolts from the vertically split housing and to take the entire housing apart. There is now an exceptionally large circular cover plate which when removed exposes the entire differential and drive mechanism. The ratio of the final drive has also been altered and is now 4.25 to 1. The front axle is also entirely new and is now the Elliot type with a knuckle which is designed to give a castor effect to the front wheels.

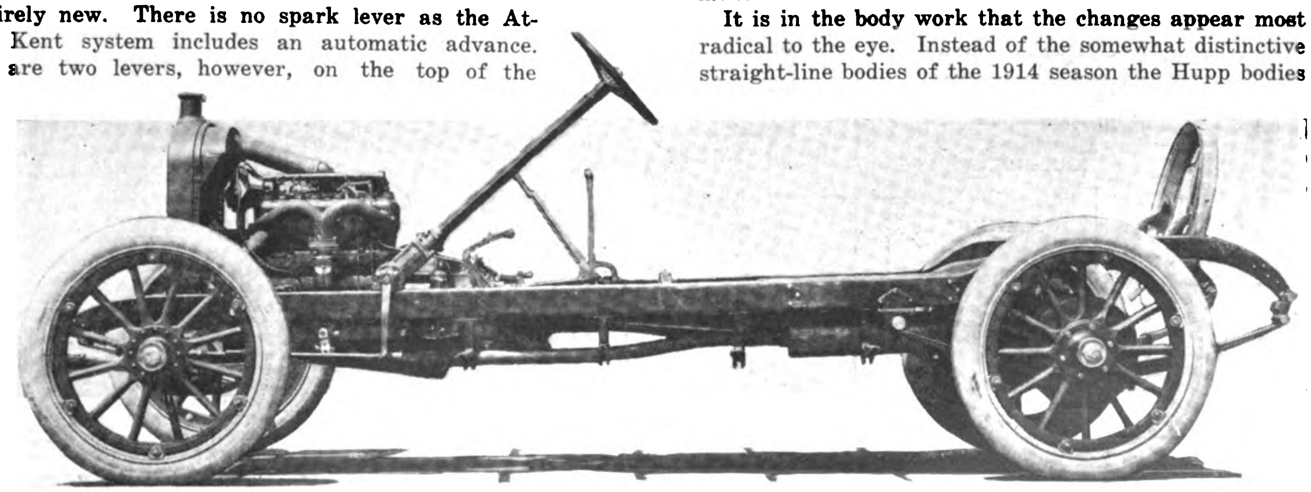
In altering the spring design an exceptional amount of attention has been given to the placing of grease cups on all spring connections. There is also an inter-leaf oiling scheme which is new. In the extremity of each leaf there is a spoon-shaped depression which is packed with graphite. This scheme has been originated by the Detroit Steel Products Co. and by its use the lubricant need be inserted between the spring leaves but once in a season.

The same steering gear is used as in the previous model but the steering wheel is now 18 inches, whereas it was formerly 17 inches. The arrangement of levers on the top of the steering wheel and the linkage in transmitting the motion to the throttle and air control of the carbureter is entirely new. There is no spark lever as the Atwater Kent system includes an automatic advance. There are two levers, however, on the top of the steering post. One of these is the ordinary hand throttle lever and the other operates in conjunction with a flap air valve on the new Zenith carbureter. When moved over in one direction it cuts off the entire air supply of the carbureter, furnishing the rich mixture required for easy starting. When moved to the other extremity it opens to the outside air, permitting of extra air for high-speed work.

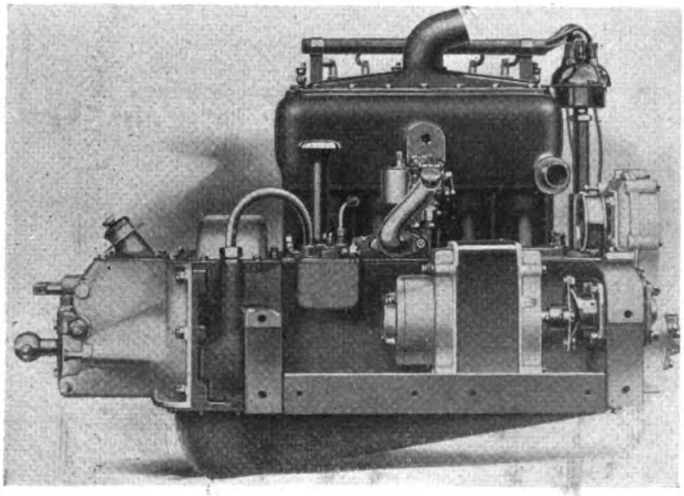
The wheels are larger than they were last year. The tires are now 34 by 4 inches, whereas on the preceding model they were 33 by 4. The tire carriers are the same on the touring car, but on the roadster they are now carried under the rear deck.

Various little details increasing the comfort in the operation of the car have been made a subject of study. An example of this is in the pedals, which are now adjustable and which are provided with exceptionally large foot pads. There is now also a side support for the foot in operating the accelerator pedal. Owing to the reversal of the clutch the pedal operation is fully 50 per cent. easier than it was in the former model.

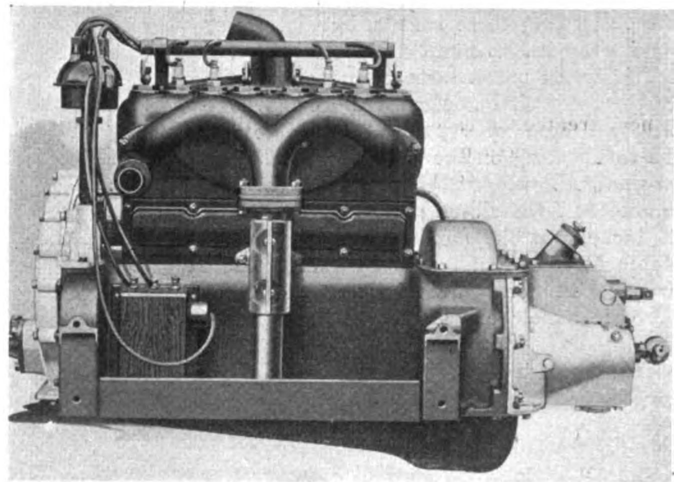
It is in the body work that the changes appear most radical to the eye. Instead of the somewhat distinctive straight-line bodies of the 1914 season the Hupp bodies



Side elevation of 1915 Hupmobile chassis, showing left drive and center control, and also new tire carrier at rear



Intake side of 1915 Hupmobile motor. Note mounting of Westinghouse unit and horizontal type Zenith carbureter



Exhaust side of new Hupmobile motor, showing mounting of Atwater Kent system with automatic advance

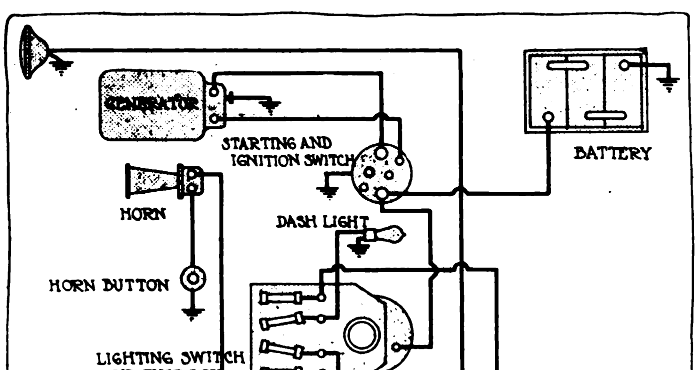
are now a full molded streamline construction. The sloping hood and cowl form a continuous curve which is not terminated at any point on the body but which is swept directly to the rear end of the car. A new radiator which makes a more fitting entrance of the streamline form and which at the same time gives a gain in capacity of 2.5 gallons, by the use of hexagonal in place of square cells, has been fitted.

Two standard types of body will be furnished, the roadster and touring car. The price of each is $1,200, fully equipped. The standard colors are blue-black bodies with maroon running gear and nickel trimmed. The cars come fully equipped with a new design of one man top, and a new type of rain vision windshield.

Motor Is More Powerful

The power plant of the Hupmobile is a four-cylinder, 3.375 by 5.5-inch motor, with the cylinders cast in a single block. The increase in piston displacement on this new motor has been from 182.5 cubic inches to 196.8. The cylinders are still offset .625 inch. This motor has a compression of 75 pounds gauge. Pistons are gray iron and carry three diagonally split rings. The piston pins are of steel hardened and ground and clamped in the connecting rods, turning in the bearings formed by the piston bosses. The bearing surface provided here is .875 inch in diameter and .175 inch in length. The piston pins are hollow.

Connecting-rods are drop forged, heat-treated, acid open-hearth steel. The bearing caps are fastened by 4.375-inch nickel-steel bolts, secured by cotter pins. The crankshaft is a 40-50 carbon open-hearth steel. All the bearing surfaces are ground and the three bearings are of generous length.



Wiring diagram of the electrical system on the 1915 Hupmobile

The front bearing is 2.5 inches long and 1 9-16-inch diameter, the center bearing 2 inches long by 1.625 inches diameter and the rear 3 inches long by 1 11-16 inches diameter. All the crankshaft bearings carry phosphor bronze bushings lined with babbitt, machined and reamed in place with a final hand fitting. The bearing bushings are split and can be adjusted by removing the pan on the bottom of the crankcase. The crankcase is a modified barrel type.

Adjustable Silent Chain

The camshaft is driven by Coventry silent chain at the front end of the motor. It can be adjusted for tension without removing the chain cover. The camshaft is also carried on three phosphor bronze bearings, the front bearing being 2 1-16 inches in length and diameter, the center bearing 1.375 inches long and 2 inches diameter and the rear bearing 1.375 inches long and 1 15-16 inches in diameter. The valves have a clear diameter of 1.15 inches. They have 45-degree seats and are forged in one piece from tool steel that will remain hard at red heat. The Hupp engineers claim that this type of valve will seldom if ever require regrinding. In place of the cover plates which were formerly used over the valves there are now screw plugs. The followers which are actuated by the cam are mushrooms. The chamber which contains the valve springs is inclosed within an oil-tight cover so that the contact between the valves and the tappets takes place within an oil bath.

The oil is circulated by the flywheel. The flywheel rim is close to the bottom of the oil pan at its deeper part and the oil that adheres to the flywheel is carried around with it and thrown with considerable pressure, due to the centrifugal force of the flywheel, into a tube from which it is carried to the different working parts of the motor. The face of the flywheel in the new motor is very much wider than that of the previous model and hence a larger volume of oil is forced through a pipe of the same diameter, increasing the pressure and giving much better lubrication at high motor speed. This year the oil leads to the cylinders have been done away with, as experiments have shown that sufficient oil from the cylinders is thrown from the crank-end bearings in the form of mist.

Clutch Action Is Reversed

As mentioned, the clutch acts in the exact opposite direction from that used on the former model. That is, the friction on the clutch thrust is taken by a bearing in the gearbox instead of the motor. The thirteen disks are of hardened saw steel 13 inches outside diameter and 1-16 inch thick.

Outside of separating the gearbox from the engine, it remains the same as in the previous car. It is a selective sliding type furnishing three forward speeds. The gears are 6-8 pitch with .75-inch face. The small gears are electric nickel-steel and the large gears acid open-hearth. The gears are heat-treated or case-hardened, according to the requirements of their carbon content. The bearings of the gearbox are annular balls and the front bearing, which is made of extra large diameter, not only carries the gear load but also is the bearing that takes the thrust of the clutch. This is a new feature in this model. The diameter of the gear shafts is 1.25 inches and they operate on four integral keys. The jackshaft is 1.25 inches in diameter. Shifting is accomplished by shifter forks operating on sliding shafts. This year the Hupp gears are run in heavy grease, whereas in all former cars they were oiled by a cylinder lubricant.

Rear Axle Construction Accessible

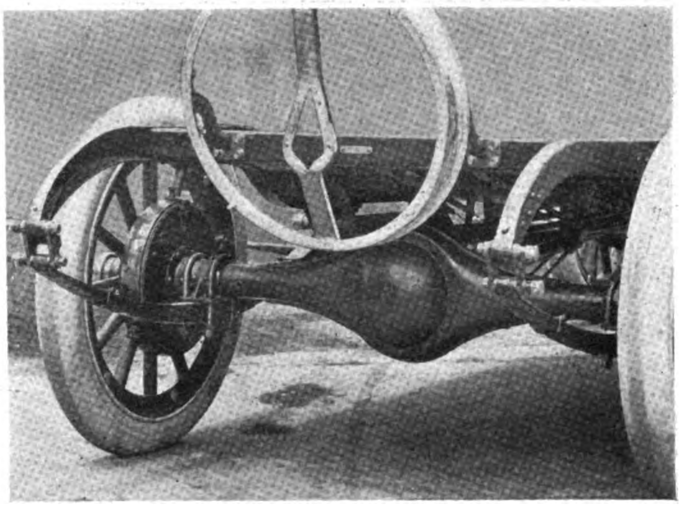
The rear axle is a floating design. Either of the axle shafts may be withdrawn from the housing without jacking up the wheel. The casing is of pressed steel with the gears and differential mounted in a malleable iron carrier. The differential is a bevel type running on annular ball bearings. It has four pinions. The gears are 6 pitch with .75-inch face. In adjusting any of the mechanism of the rear axle an accessible arrangement has been provided by means of which either the entire differential, together with the bevel pinion and gear or the large gear in the differential may be removed as a unit.

In re-designing the axle a new exterior appearance is given by the use of hub caps instead of the flat plate on the previous model, especially in combination with larger wheels and the altered rear spring design. Artillery type wheels are used with twelve 1.5-inch spokes.

The front springs are 37 by 1.75 inches, which is 3 inches longer than in the former Hupmobile and the new semi-elliptic rear springs are 52 by 2 inches in length and are shackled to an up-swept portion of the main frame.

Equipment Is Unusually Complete

The equipment of the car is exceptionally complete this season, and in lighting and starting has been re-designed. It is the Westinghouse 12-volt type, 12 volts being used both for starting and in each of the lamps. Non-glaring headlights, in which the upper part of the front lens is corrugated, are now employed. The tail light has another exclusive feature in that it illuminates the road directly behind the car.



Rear construction of new Hupmobile, showing underslung semi-elliptic rear springs and bracket tire carrier

The electric starter is at the front right end of the motor and is connected directly by silent chain, giving a ratio of 2.64 to 1 to the crankshaft. Turning a switch lever on the dash starts the engine and at the same time closes the ignition circuit. As soon as the speed increases to a point where the car would be traveling 9 miles an hour on high gear, the electrical unit becomes a generator and starts charging the battery. At about 18 miles per hour the maximum charging rate of 8 amperes at 14 volts is reached. The motor can never stall for, should it cease to operate, merely depressing the clutch pedal will cause it to be started again. The timer for the Atwater Kent system is driven by spiral gears from the front end of the camshaft. The current is taken from the storage battery and operates at 12 volts.

The Westinghouse system is now included as stock equipment on all cars. There are also the headlight dimmers, license brackets, rain vision windshield, silk mohair top, speedometer, robe rail, foot rail and cocoa mat included with the car. The rims are demountable and one extra rim and tire carrier is furnished. The weight of the touring car when fully equipped and with the tanks empty is 2,650 pounds.

A Rift in the Stormcloud

ENGLISH manufacturers are finding the supplies from Europe for building automobiles cut off and already they have started conserving stocks of parts for commercial vehicles that may be needed in the war. They find that the great factories of Belgium that have been supplying forgings, castings, axles, gearsets and numerous other parts, are closed because of the war.

This is America's opportunity. England can secure from this country many of these parts that she has hitherto looked to Belgium, France and Germany for. The possibility of this demand is the one rift in the overcast skies that have so suddenly clouded the automobile world. Motor cars are being needed for the war and will continue to be needed. The government has taken over some of the largest German factories. The Belgian government took over one or two of its largest car factories the moment war was declared. The same is true in France. There is little hope for America to sell supplies and completed parts to Germany, Belgium or France, but the opportunity for doing business in England is brighter. It is worth a good honest effort. Business done with England now under the stress of war conditions may well, and honorably, furnish an introduction for the American products which will redound to the permanent advantage of our industry.

Eight Cylinders

IT is more than possible that a new factor has entered into what has become known as The War of the Cylinders in that the eight-cylinder motor, which up to the present has been largely confined to the output of one manufacturer so far as automobiles are concerned, will make its appearance on the American market next year.

For several years one of the leading French builders, De Dion-Bouton, has built eight-cylinder machines, and now this concern builds them in many different models. These machines are not untried creations, but rather designs that have been worked out for many years and have stood up, have proven themselves to be equal to the requirements.

The eight-cylinder motor looks like an enormity when contrasted with the six. The increase of two cylinders seems a big addition, but when the six is placed alongside the eight with its cylinders mounted V fashion in two sets of four, the eight really impresses the motor student. It is shorter than the six and has a crankshaft that rivals the four-cylinder one in simplicity. It is shorter than the six; in fact, due to the V mounting of the cylinders in the eight and to coupling two connecting rods to each throw, the motor is little longer than a four. The short crankshaft eliminates the whipping tendency met with in the long crankshafts in several of the six-cylinder designs.

The eight-cylinder motor with its cylinders cast in two L-head groups of four each makes a simple manufacturing job in that one camshaft mounted in the angle between the cylinder groups in the top of the crankcase serves for both intake and exhaust valves for the eight cylinders. The intake piping is considerably simplified as the carbureter is positioned midway between the two cylinder groups.

Judging from the performances of eight-cylinders now on the market the gasoline consumption is most satisfactory. In fact, eight-cylinder motors with an official rating between 20 and 25 horsepower have averaged from 20 to 22 miles to the gallon in regular country touring.

Whether the struggle for supremacy which has been waged for years between the four and the six will now be transferred to the eight, or if all three types of motors will continue in the arena, is a question that only time will solve. The aggression with which the eight is taken up will prove a potent factor. Today the public will not launch the arguments against the eight that were pressed against the four and the six, namely more cylinders, more valves, more spark plugs and more parts to go wrong. The complications offered by the two additional cylinders cannot be seriously considered. True, there will be some problems of value accessibility to deal with. The construction of the lower end of the connecting rod will call for attention, but if the eight can prove its claim to greater flexibility than the six, if its inherent merits of shorter crankshaft, more compact design, etc., carry that weight which they apparently should, then it will not be surprising if 3 or 4 years hence we find ourselves approaching a period of eight-cylinder popularity.

Motor Industry Supports 22 Per Cent. of Michigan's Population

90,673 Workers Employed in State's Automobile Factories and Stores, 71,104 Being the Number Detroit Keeps Busy

DETROIT, MICH., Aug. 13—The automobile industry ranks first as far as the total number of employes is concerned in the state of Michigan from statistics gathered from the annual report of the Department of Labor of Michigan for the year 1913. These records were obtained at different seasons of the year, some in May, some in August and some in November; for example, Chalmers, taken July 29, 1913; Packard, October 22, and Timken-Detroit, May 8.

Out of a total of 407,552 employes working in 11,823 factories, plants, shops, stores or other places of business employing wage-earners, 90,673, or 22.2 per cent. are employed in 582 concerns, manufacturers or retail stores, having some relation to the general automobile business. This total of 582 represents only 5.7 per cent. of all the business concerns visited by the labor officials.

From among the 90,673 men and women, boys and girls, earning their living in the automobile industry, 71,104 were employed in the city of Detroit, or 78.4 per cent.; and among them 37,662 or 41.6 per cent. were working in twenty-seven automobile manufacturing plants in Detroit.

Forty-two Car Makers in State

The number of automobile makers in the state, according to the annual report was only forty-two in 1913, or twenty-four less than in 1912. This does not mean that twenty-four concerns went out of business, but while some of them did, the majority were either absorbed by other companies or ceased making cars and continued in some other line.

While the general average of daily wages paid in 1911 was $2.23 for each of the 359,752 employes concerned in the record, it increased to $2.31 in 1912 and concerned 404,480 workers, and was $2.41 in 1913 for each of 407,552 employes, which means a net gain of 18 cents.

The average daily wages of the factory men increased 10 cents over the average of 1912 and 15 cents over that of 1911.

Factory women's increase was only 1 cent over 1912 and 9 cents over 1911. The average daily wages of girls shows an increase of 3 cents over 1912 and 1911, whereas, the wages of boys decreased 1 cent over 1912, but were still 17 cents higher than in 1911.

The superintendents' wages decreased 1 cent as compared with 1912, but were still 7 cents higher than in 1911. Foremen's wages increased 2 cents over 1912 and 21 cents over 1911.

	1913	1912	1911

Record Exports in Last Fiscal Year

30,136 Cars Worth $27,797,642 and $4,159,454 Worth of Tires Show 13-Fold Growth in 10 Years

WASHINGTON, D. C., Aug. 15—The secretary of commerce today announced that exports of motor cars from the United States in the fiscal year ended June 30, 1914, were the largest on record. Their total, including shipments to Alaska, Hawaii, and Porto Rico amounted to $40,136,565, as against $39,325,000 in 1913, the former high record year. The year's total included 30,136 complete cars, valued at $27,797,642; tires, $4,159,454; motor car engines, $1,391,893 and miscellaneous parts, not specified, $6,787,575.

With the sole exception of 1908, every year during the past decade has shown an advance in the value of American motor cars sold to foreign countries. In the fiscal year 1904, according to the bureau of statistics, the value of motor cars exported was $1,895,605; in 1909, $5,387,021, and in 1914, exclusive of parts and shipments to our own non-contiguous territories, $26,574,574, having quintupled in 5 years and increased thirteen-fold in a decade.

Europe Bought Nearly Half

Europe bought nearly one-half of our entire sales of motor cars to foreign countries last year, although some shipments are for reshipment to other parts of the world. To the United Kingdom the exports amounted to 7,222 cars, valued at $5,853,127; to Germany, 1,435, valued at $1,059,249; to France, 1,429, valued at $1,224,130; and to other countries of Europe, 3,271, valued at $2,580,428. Canada and Australia also are important markets, the former having taken 4,624 cars, valued at $5,919,776 and the latter, including other British Oceania, 4,244, valued at $3,695,595. To South America as a whole we sold last year 1,985 motor cars, valued at $1,939,212, and to Mexico, 167, valued at $256,675.

The growth in exports of motor cars has been accomplished by a corresponding decline in imports of like articles, the total having fallen from 1,624, valued at $2,905,391, in 1909, to 300 cars, valued at $620,493, in 1914, a new low record for the decade. Of the year's imports, 134 were from France, 40 from the United Kingdom, 55 from Italy and 21 from Germany.

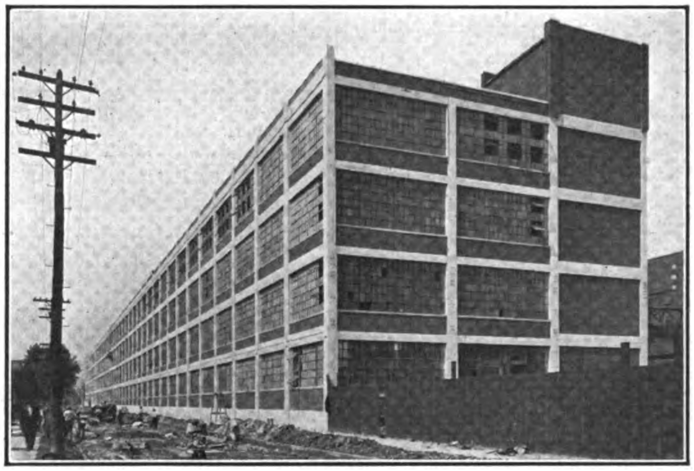
German Motor Exports Shrunk Before War

DETROIT, MICH., Aug. 17—From the official records of the German government it is shown that the German exports of automobiles, motor cycles, parts and accessories during the first 5 months of 1914, ending with May, show a total decrease of $3,016,000 as compared with the corresponding periods of 1913. In other words, while the German manufacturers sold outside of the Fatherland $11,443,750 worth of motor cars, motor cycles, parts and accessories from January 1 to May 30, 1913, this year, during those 5 months, they sold all told only $8,427,750 worth of the same goods.

The detailed reports as to the exports to each foreign country are not at hand, only the totals. Thus it is seen that up to the end of May, 1914, a total of 3,227 pleasure vehicles having a total value of $6,158,250, or an average value of $1,908 each, were exported. In 1913 the exported cars numbered 3,630 having a value of $8,381,500 or $2,309 each. Thus for this year 403 less pleasure cars were exported, which meant a difference of $2,223,250 to the manufacturers while the 1914 car's average value was $401 less than that of 1913.

The number of commercial cars—trucks and delivery vehicles—exported during the first 5 months of 1904 was 294 as compared with 468 in 1913. Their value was $904,500, as compared with $1,564,250 in 1913. The price was $3,076 per truck this year and $3,342 last year. The sales were 174 trucks less in 1914 than 1913 and in dollars it represented a loss of $659,750.

Up to the end of May, 1914, the German manufacturers had exported 1,428 motorcycles valued at $304,000, or an average of $212 each, while in 1913 they had sold 1,972



New assembling plant added to Dodge factory

motorcycles, of a value of $393,500, or $299 each. The decrease this year was thus 544 motorcycles and $89,500.

The export of automobile parts during the first five months of 1914 amounted to $861,500, or $144,500 less than in 1913.

Automobile and motorcycle motors to the value of $199,500 were exported this year up to the end of May, and this represented an increase of $101,000 over the first five months of 1913.

The total value of pleasure vehicles and commercial cars exported during the first 5 months of 1914 was $7,062,750, while in 1913 this item totalled $9,945,750, or nearly $2,900,000 more for the first five months of 1913.

Big Dodge Addition About Finished

DETROIT, MICH., Aug. 17—Dodge Bros. announce the practical completion of the assembling plant which has been added to the factory. This building is 876 feet in length and 70 feet in width and four stories in height and is constructed to withstand a floor strain of 350 pounds to the square foot. With the addition of this building the floor space of the factory which is to be devoted to the manufacture of the Dodge Brothers' car is 18 3-4 acres.

More Cowles Patents for Packard

DETROIT, MICH., Aug. 17—In accordance with its policy of continually strengthening its patent position, the Packard Motor Car Co. has followed up its purchase of several years ago of the Cowles motor vehicle patent applications and is now having issued to it a number of divisional patents based upon the original patent No. 1,050,810, the application for which was filed on September 6, 1901.

The latest of these to issue is that relating to the truss rod construction, taking into consideration torsion tube design and trunnion springs. This is dated August 11, 1914, and its patent number is 1,107,042. There are two others of these divisional patents which have been issued, and more to be granted in the near future. Still others are likely to be held up at the patent office for a few months longer in accordance with usual patent office procedure. The other two issued are: the main patent, No. 1,050,810, dated January 21, 1913, and relating principally to an improved steering wheel hub and means for mounting the same, and 1,103,567, dated July 14, 1914, and relating to the running gear and steering mechanism.

It must be understood that all of these divisional patents are based upon the one main patent applied for on September 6, 1901, and granted under patent No. 1,050,810. The patent office permits of such divisions under main patents, and the Packard company is taking advantage of this ruling for its strengthening.

Edward P. Cowles is the originator of the ideas involved in the Cowles patents, and holds the unique distinction of being the designer of the first automobile invented by J. W. Packard, while he was in the latter's employ at Warren, O., in 1896. Two years later, in 1898, Mr. Cowles began work on the plans for a motor vehicle of his own invention, and shortly afterward the specifications were completed and proceedings instituted for patents. All these rights have since been assigned to the Packard Company.

The Patent Department of the Packard Company, of which Milton Tibbetts, Packard patent counsel is the head, attaches considerable significance to these Cowles patents for obvious reasons. The divisional patents growing out of the broad claims of the main original patent relate to such features as an improvement in rear axle construction, interchangeable wheels, spring construction, frame construction, body design, steering connections, rear signal device, mounting of the motor, shock absorbers, and so on.

Patent No. 1,107,042 has seventeen claims which deal broadly with the construction of the car. The particular points which are brought out in the patent are the flexible connection of the sprung portion of the car to the unsprung portion and the method of transmitting the torque strains flexibly through the torque members.

Patent No. 1,050,810 has eight claims relating to the connection between the axle and the front wheels. It covers particularly the trunnion method of connecting the wheel hub to the axle. The construction particularly mentioned is a combination of a forked trunnion support in which the trunnion has its arms extended so that the jaws are above and below the inner hub member, and arms which connect the wheel bearings to the vertical trunnion.

Patent No. 1,103,567 relates to the connection of the steering gear to the front wheel spindle. The particular point covered is that the tread of the wheel at the point of contact with the ground is vertically in line with the large bearing mounted at the base of the spindle. In other words, this specifically deals wtih the pivot point of the wheel being vertically in line with its axle support, thus providing the easy steering feature generally sought in front axle design.

More Cars Sold for Australian Market

DETROIT, MICH., Aug. 10—F. Z. Eager, an American automobile importer established in Australia, was here recently and placed orders for about 1,000 cars, or 50 per cent. more than last year.

"An American car costing $1,000 here is listed at $2,000 when it finally gets on the show room in Australia," said Mr. Eager. "Duty and other customs charges bring the car up to $1,250, and after the freight to the Australian port is added, with the incidental expenses, the car will stand at $1,500. Then other charges are to be added, and the dealer's percentage or commission, so that the car must be sold at $2,000.

"Even so, the sale of American medium-priced cars is steadily increasing, as they have proven through tests, trials, hill-climbs, etc., that they are best suited for the Australian roads. These are in many parts of Australia about what they are in South America and Africa, that is, they are called roads, but actually nothing like a road exists. The variety of roads is such that it is the best testing ground nature affords. And the very reason why the American cars are now so well liked is because the people now know that the American roads are very bad, and also require cars that will stand the biggest stress than can be found.

"The rich Australians purchase the high-priced cars made in Europe, but not so much because they consider them so much more worthy, but because it is the style. The wealthy man or woman who has not his or her big European car is quite an exception."

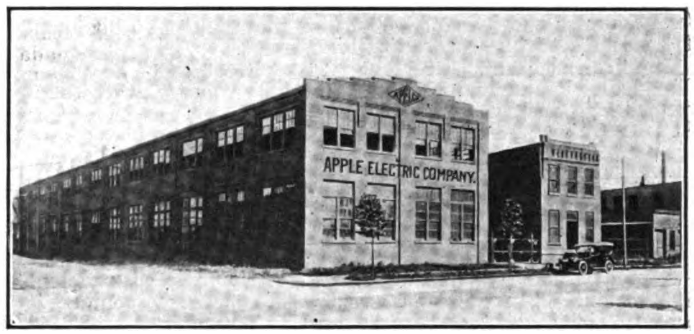
Splitdorf-Apple Plants All in Newark

NEWARK, N. J., Aug. 17—With the purchase of 5 acres of land, buildings giving 70,000 square feet of floor space and an office building all ready for occupancy, the Apple Electric Co. is preparing to move its headquarters for the manufacture of automobile and motor boat starting and lighting outfits and batteries from Dayton, O., to Newark, N. J. The move will not be immediate, however. The Apple company products will continue to be manufactured at Dayton until the new plant has demonstrated its efficiency to turn out the work in volume and up to the Apple standard of quality in every respect. This plan was decided upon to eliminate all chance of the slightest hitch in making deliveries.

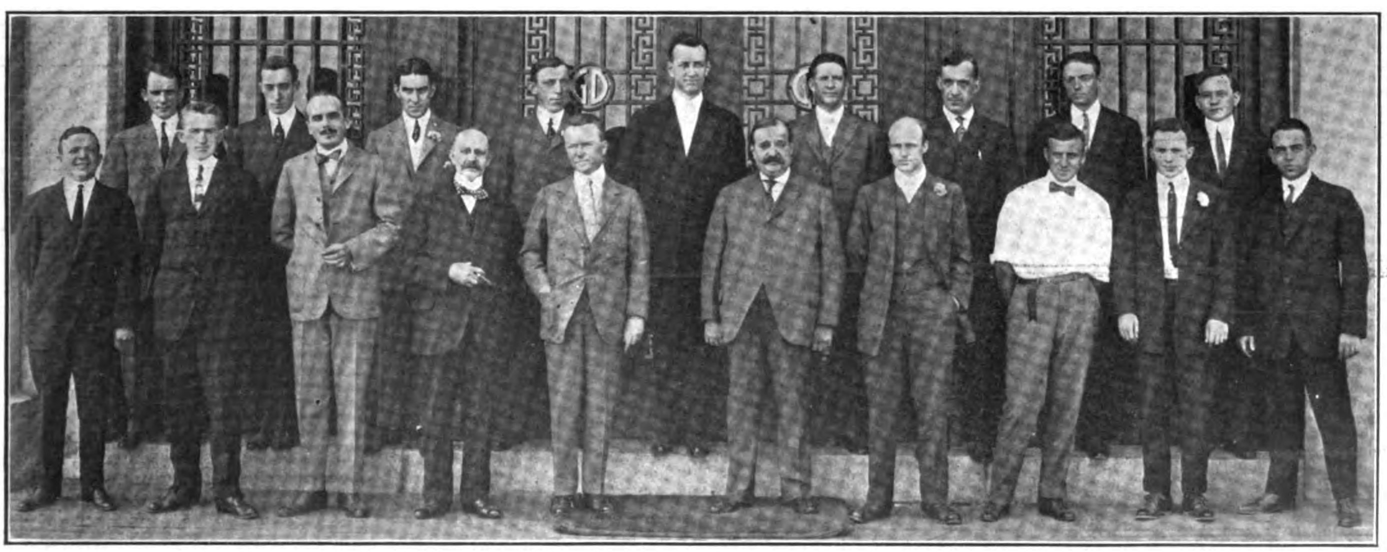
The important move follows the drawing together of the manufacturing and selling policies of the Splitdorf Electrical Company with those of the Apple interests, and the controlling of the Apple output by the dominant Splitdorf sales organization. The Splitdorf executive offices and manufacturing plant have been located in Newark for two years, and, with mutual interests at stake, a greater degree of co-operation from closer association is anticipated.

The new Apple factory will be the buildings formerly occupied by the Lansden Electric Co., and the surrounding ground purchased by the Apple company gives ample room for almost unlimited extension should occasion arise.

MILWAUKEE, WIS., Aug. 18—The Federal Rubber Mfg. Co., Milwaukee, will celebrate "Federal Day" on next Saturday, August 22, by entertaining its 2,500 employees and their families at an all-day picnic at Waukesha beach, Pewaukee lake.



New Apple Electric Co.'s factory in Newark



Group of the Gray & Davis salesmen and officers at the convention held at the factory August 3-8. Top Row—Left to right—G. C. Marr, purchasing agent; E. G. Acker, production manager; J. H. Maxwell, secretary; O. W. Cook, assistant factory supt.; C. M. Tichenor, chief mech. engineer; E. R. Hodges, R. W. Carr, K. Greenleaf, C. Z. Sedgley, sales engineers. Bottom Row—Left to right—A. G. Haskell and G. L. Gaskell, sales engineers; C. O. Sacks, advertising manager; E. E. Schwarzkopf, sales manager; Wm. Gray, president; W. H. Gray, general manager; E. F. Wackwitz, sales engineer; W. B. Moses, electrical engineer; R. Hoyt Moses and A. Driver, sales engineers. Three of the salesmen who attended the convention and also Mr. Picard, manager of the Ford sales department, were not at the factory when the photograph was taken. The next convention will be held early in January

Goodyear Returns to Old List Tire Prices

Is Only Company To Do So—Top Market Prices of Crude Rubber Prevail —Some Increases

NEW YORK CITY, Aug. 19—The Goodyear Tire & Rubber Co., Akron, O., has returned to the list prices in force before the war scare and has instructed all its branches accordingly. None of the other companies has announced a reduction in prices.

Last week the principal tire companies, with a few exceptions, had advanced prices from 12 1-2 to 20 per cent. Some of the smaller companies had not announced changes. This week practically all have reached the higher level, but none have advanced beyond the first increases.

The crude rubber situation, according to F. R. Henderson, of the rubber importing firm of Henderson & Korn, is practically unchanged. The high price of $1.10 for plantation and $1.12 for Para still holds without an advance, and there is no more rubber in America now than there was a week ago. Neither is it likely that there will be any more for some time.

Press cables from Europe during the past week have indicated that shipping might be resumed within a short time. Without being pessimistic Henderson stated that the "short time" might be months. Private cables from London to the Company state that the "resumption of shipping at first opportunity may mean many months." This is regarded as significant, inasmuch as it is the scarcity of ships and not of rubber which has caused the shortage in America.

Ajax-Grieb, Kelly-Springfield and Michelin, which did not raise last week, are still holding to their old prices. As officers of the two former stated, they will not raise until the manufacturing cost actually increases.

Empire, Federal, Firestone, Fisk, Goodrich, Diamond, Goodyear, Pennsylvania, Republic and United States advanced last week 12 1-2 and 20 per cent. Later advances are: Lee, 12 1-2 per cent.; McGraw, 15; Racine, 15; and of the importers, Englebert, 10 per cent. Gaulois is awaiting advices from the factory in France before it alters prices.

A comparison of the new and old prices in a 34 by 4 size of those which have followed the raise is: Lee Regulars—Plain, $19.10, $25.85; non-skid, $33.10, $37.25. Lee Puncture-Proofs—Plain, $38.25, $43.05; non-skid, $47, $52.90. Lee red tubes, $5.75, $6.45.

McGraw—Plain, $24.35, $28; non-skid, $26.05, $29.95; red tubes, $5.45, $6.25; gray tubes, $4.90, $5.65.

Racine—Plain, $26.80, $30.80; non-skid, $33.50, $38.50; red tubes, $6, $7.20; gray tubes, $5.40, $6.50.

The 12 1-2 per cent. advance in Pennsylvania does not include tubes or Vacuum Cup tires which, the company having a good stock, were increased but 5 per cent. The red 34 by 4 tube went from $7 to $7.35 and the gray from $5.30 to $5.95. The vacuum cup in the same size was increased from $41.95 to $44.05. Smooth treads were increased from $28.30 to $31.85.

The Englebert increase was thus: Plain, $32.20, $35.50; rubber non-skid, $36.80, $40.50; steel-studded, $41, $45. Tubes unchanged.

Market Reports for the Week

A further reduction in prices occurred this week in the markets. Tin, this week, was very erratic with violent fluctuations. Starting the week at $64 per 100 pounds, it rose to $65 and gradually dropped to $40 and then closed at $49. At the latter part of the week there were quick sales of small lots. More tin is expected from London but the situation from the Straits Settlements is not so clear. The cargoes afloat for this country at the moment are 920 tons, of which 240 tons are due before the end of the month. There is a small demand from domestic customers in copper. The sales are confined to August and September shipment. Up-River Para has dropped $0.30, closing at $0.90. A syndicate is reported to have bought up the bulk of the supply in London with the intention of shipping it to this country. Also there is a prospect of an increase in the supply of Brazilian rubber.

Swartz Carburetor Co. Organized

COLUMBUS, O., Aug. 17—The Swartz Carburetor Co., which was incorporated recently with an authorized capital of $50,000, has been organized by the election of the following officers: M. A. Corbett, president; Thomas A. Swartz, vice-president; R. J. Corbett, secretary; and F. E. Stevens, treasurer. The company will make a carbureter invented by Thomas A. Swartz which is claimed to give greater mileage and also to be more flexible than existing carbureters. The factory will be located in Columbus.

Saxon Co. Takes Over N. Y. City Branch

NEW YORK CITY, Aug. 18—The Saxon Motor Co., Detroit, Mich., has taken over the business of its New York City agent, L. A. Van Patten, Inc., 251 West Fifty-seventh street, making it a factory branch. The company expects to use the branch in developing the foreign trade as well as that in the New York territory. It has leased an upper floor of the building at Fifty-fourth street and Broadway, where the A. Elliott Ranney was located, for a service department. It is to be known as the Saxon Motor Co., of New York.

The company is contemplating changes in the perfection of the new dealer organization in Boston, California, Dallas and Denver. It has just arranged with the Liniger Implement Co. to replace the Stefart Too-Zer Co., Omaha, Neb., in the selling of Saxon cars. The Bond Motor Co. replaces the Saxon agency in Kansas City, Mo. The Essex Motor Car Co. now has the Newark, N. J. agency.

Philadelphia Oakland Branch Entertains

PHILADELPHIA, PA., Aug. 14—More than fifty dealers from Eastern Pennsylvania, Southern New Jersey, Maryland, Delaware and Virginia assembled here yesterday as the guests of Ted Johnston, manager of the local factory branch of the Oakland Motor Co., 227-229 North Broad street. A thorough inspection of the branch, its equipment and facilities, and of the new model Oaklands was followed by a dinner at the headquarters of the Philadelphia Automobile Trade Association.

Next Tuesday the Maxwell Motor Co., Inc., will give a reception and luncheon to the Maxwell dealers in the Philadelphia territory. During the luncheon, "From Molten Steel to the Automobile" will be shown in motion pictures.

Frisco Trade Unites Against Price Cutting

SAN FRANCISCO, CAL., Aug. 10—After hearing R. H. Daniels, head of the service bureau of the Goodyear Tire & Rubber Co., Akron, O., in a talk on upholding the prices on tires and other rubber goods and accessories made by the tire concerns and directly interesting the automobile supply and accessories dealers, about 120 decided unanimously to form the Motor Car and Accessories Trade Assn., the officers of which will be elected within a short time.

President J. A. Marsh, of the Motor Car Dealers Assn., presided, and spoke in favor of the co-operation, not only of the supply and accessories dealers, but also of the motor car agents, as the whole trade was interested in the matter, and should help in eliminating the price cutting policy. "Trade will be better for all concerned," said Mr. Marsh, "and it will help the legitimate concerns."

Dealers in Stockton, Oakland, and other cities in this territory have already started organizations for the same purpose, and district attorney H. L. Hynes, Alameda county, was quoted as holding that such organizations do not violate the Cartwright anti-trust law. The United States District Attorney was also reported to have given his opinion that such trade organizations do not conflict with the federal law and that they were state issues.

Hays Buys Michigan Buggy for $45,000

KALAMAZOO, MICH., Aug. 17—Judge Sessions, of the Federal Court, Grand Rapids, Mich., has decided that the bid of $45,000 made by former Mayor Charles B. Hays, of this city, for the plant of the bankrupt Michigan Buggy Co., should be confirmed, and thus the sale of that property, which has given way to many bids which had been refused because they had not reached the sum estimated as minimum by the Court becomes history.

Mr. Hays bought the plant purely as an investment, and does not intend to enter the manufacturing field.

DETROIT, MICH., Aug. 11—Shipments of the 1915 Hupmobile models were started today. During the next ten days only thirty-five cars will be the daily output, but after that time the output will be doubled.

Receiver for Savage Co.; Officers in Jail

DETROIT, MICH., Aug. 14—James J. Larmour has been appointed receiver for the creditors of the Savage Motor Car Co., whose officers are held in the county jail, Detroit, having been placed under arrest August 10 by government inspectors for using the United States mails to defraud. After a preliminary hearing, E. E. Taylor, Robert W. Fishback and Delbert H. Cummings, the three officials of the company were about to be set at liberty under $7,500 bail bonds being furnished by each, when new complainants appeared, and after hearing them Acting United States Commissioner Elmer W. Voorheis required a further bail bond of $5,000, so that each of the accused was to provide $12,500 in order to gain temporarily his liberty. Attorney C. E. Wilcox, who appeared for creditors, had prepared an involuntary bankruptcy petition and prevented the accused from drawing money from the Federal State Bank, where the company's funds were deposited.

No further action will be taken by assistant district attorney Benedict Lee until the bankruptcy proceedings in the United States court will have been disposed of. It is not yet known where the accused will be tried, as warrants have been issued against them both in Cincinnati, O., and in Detroit, and it will probably be in the city where a true bill is first returned.

Details concerning the financial standing of the Savage company are not available now. Reports have been published in daily papers, but Receiver Larmour stated that they were all imaginary.

Dodge Bros. Sue to Protect Name

DETROIT, MICH., Aug. 17—Dodge Bros. have filed a suit in the Circuit Court of Michigan against the Dodge Motor Car Co. to restrain the latter from using the name Dodge on its product, in its advertisements, in fact in any matter concerning their business.

It is claimed by Dodge Bros. that the officers and stockholders of the Dodge Motor Car Co.—Alvin M. Dodge, J. Moyer Leman, E. O. Millay, Edwin Herzog and George E. Sheldrich—are trying to profit by the name of Dodge Bros., which has existed for the last twelve years in Detroit, and whose business is so well established and known throughout the country.

Mr. J. Moyer Leman, of the Dodge Motor Car Co., when asked to-day concerning the Dodge Bros. suit, said: "All we know about this suit is what we have read in the daily papers. No papers have been served on us as yet, and if they are we certainly will fight the case to the limit."

Delay for Oldfield Patents Bill

WASHINGTON, D. C., Aug. 15—Of great importance to the motor car and accessory trade of the country is the action of the House committee on patents in reporting favorably the Oldfield bill to codify, revise and amend the laws relating to patents. While the committee has acted favorably on the bill, it is understood no action will be taken at this session. Probably during the short session, which begins in December, the bill will be pushed through by its author. In order that those vitally interested in the changes proposed will know just exactly what the bill provides, the text of the bill, as reported to the House of Representatives, is herewith presented in part:

Section 4884 is to be amended so that every patent shall contain a short description of the invention to indicate its nature. And a copy of the specifications, claims and drawings shall be attached to the application. It shall contain a grant to the patentee, his heirs or assigns of the exclusive right to make, use or vend the invention throughout the United States for a term of 17 years.

Two years will be allowed for the work of obtaining the patent after the application is first filed. It is stated that every patent shall be limited to expire 19 years from the date of filing in this country, but this is exclusive of the time actually consumed by the Patent Office or the courts in considering the application.

Sec. 2—Section 4899 of the Revised Statutes shall be amended so that no person selling a patented article shall have a greater right to prescribe the conditions limiting its subsequent disposition than if the device were not patented.

Every person who purchases, of the inventor or constructs any newly invented machine prior to the application of the inventor for a patent or who sells or uses one so constructed, shall have the right to use and to vend to others to be used, the specific thing so made or purchased without liability.

No purchaser, lessee, or licensee of a patented article shall be liable to an action for infringement of the patent because of any breach of the contract of sale, lease or manufacture.

In Section 3 it is set forth that the district court wherein the owner of the patent may be found shall have the right to compel the granting of a license according to the circumstances stated in the bill.

Steel Orders Are in Bigger Volume

NEW YORK CITY, Aug. 14—The United States Steel Corp. has made its monthly report of unfilled orders, making the best showing in 3 months. Unfilled orders on the books at the end of July were 4,158,000 tons, in round numbers, an increase of 125,700 over the total at the end of June.

Automobile concerns are having difficulty getting supplies of a special nature. Sixty cars of glass bought in Belgium by Detroit automobile makers for windshields are held up.

Detroit Curb Pumping Stations Must Go

DETROIT, MICH., Aug. 16—The Commissioner of Public Works of the city of Detroit, has advised every gasoline stand and station within the city limits that they will have to remove by October 16 their curb or sidewalk pumping outfit.

It is the contention of the commissioner that inasmuch as the Supreme Court of Michigan recently rendered a decision in favor of the city that fruit stands must be removed, and that the city has the right to remove any obstruction on its sidewalks and curbs, that gasoline curb supplying stations are obstructions and must consequently be removed.

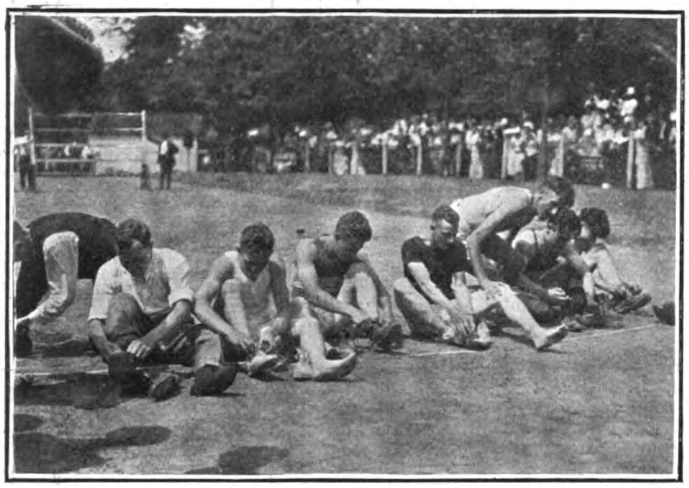
Gasoline Storage Near Residence a Nuisance

DETROIT, MICH., Aug. 17—A decision was rendered some time ago in the Circuit Court of Kent County, Mich., which may have a far-reaching effect inasmuch as the court held that the storage of a large quantity of gasoline within a few feet of a residence is a private nuisance.

The case was the one of Arthur W. Whittemore, who owns and occupies a house and lot adjacent to the Baxter Laundry Co., in Grand Rapids, Mich. The Baxter Company, which does a dry cleaning business, uses about 15,000 gallons of gasoline per year and prior to the filing of the bill in the case, had placed in its yards two large steel tanks of the capacity of 10,000 gallons each and had commenced excavating for the purpose of having these tanks placed in the ground in the northwest corner of its premises, which was the farthest possible point on its premises from its buildings and immediately adjoining Whittemore's property, the nearest tank being about eleven feet from his property. Whittemore filed a complaint for a temporary injunction, claiming that the storage of the gasoline so near to his property would be a private nuisance.

In the lower court it was held that it was a private nuisance. The Baxter company appealed to the higher court, which upheld the lower court's verdict.

NEW YORK CITY, Aug. 18—G. L. Holmes has retired as general manager of the automobile accessory department of the H. W. Johns-Manville Co., this city. E. A. Cassidy will take his place, his former position being sales manager of the department. H. H. Knepper, who has been assisting Stephen Douglas, manager of the Detroit office, has also resigned.



Two pictures of the obstacle race at the annual outing of Packard employees held at Bob-Lo, Mich., August 10, at which a total of about 6,000 of the company's working force took part. Three of the largest Detroit River steamers were used to transport the happy crowd. The features of the day were the various athletic contests, such as inter-department relay races, dashes and obstacle races, fat man races, races for small boys and for women. One of the events which was most successful, and a novelty, was a pie-eating race for small boys. There were also swimming races and other events held in the water. On account of the heavy rain the baseball and soccer games could not be held in the open and were replaced by the followers of Terpsichore in the dancing pavilion

N. Y. Fire Marshal Develops "Gasoline Peril"

NEW YORK CITY, Aug. 17—State Fire Marshal Thomas J. Ahearn, of New York, has unearthed a "gasoline peril"; and in unearthing it he has developed a "garage regulation peril" which is faced with awe and real dread by the garagemen of the state.

After figuring out that gasoline properly mixed with air and compressed "is equal to 83 2-3 pounds of dynamite" he has promulgated a set of garage regulations which, if enforced, will cost the garages of the Empire State thousands of dollars and perhaps put some of them out of business.

The move has attracted the attention of trade organizations, and the Automobile Dealers' Association of New York, has already begun an investigation of this latest official hobby of regulation.

Some of the regulations are particularly drastic. One forbids the maintaining of a repair-shop in a garage. No more pits are to be allowed. Gasoline tanks may not be maintained under sidewalks, but must be buried 3 feet underground elsewhere and proper piping carried to the garage or curb.

Torches, forges, fire, flame or any electrical apparatus capable of emitting a spark are banned. Heating shall be by steam or hot water. No building or part thereof shall be converted into a garage or used as a garage unless it is fireproof.

These are a few of the rules and regulations. There is, of course, provision for the ubiquitous permit and inspection by 1,700 deputies. The regulations go into effect December 1, 1914, and a "reasonable time" will be allowed for the altering of existing structures.

New Westcott for $1,150

RICHMOND, IND., Aug. 17—The price of the series B Westcott has been reduced to $1,150 for 1915. The car is equipped with a Northway motor, the Atwater Kent ignition system and the Jones electric starting and lighting system. The Westcott Motor Car Co. states that an increase in business is expected during the coming season.

Tribute for Charity in Kansas City Fuel War

KANSAS CITY, MO., Aug. 17—Five charities of this city are to benefit by the latest move in the gasoline price-cutting campaign now raging between the Standard Oil Company and the independent refineries. The Rockefeller corporation has announced that it will give one-half cent to charity for each gallon of gasoline sold at its filling station here in August. The money will amount to between $2,000 and $3,000, it is understood, and will be divided among the Associated Charities, The Jewish Educational Institute, Mercy Hospital, the Orphan Boys' Home, and Swope Settlement.

The last reduction here brought gasoline from 10.8 cents to 10.3 cents a gallon. The charity-sharing plan will not be extended to other cities, it was declared here. So far, the independent refiners have made no similar move.

Permanent Motor Pavilion at Indiana Fair?

INDIANAPOLIS, IND., Aug. 17—There is a movement on foot for a permanent building at the Indiana State Fairgrounds to house motor car exhibitions, which would be held annually during the fair. It is regarded as likely that the Indiana legislature, next January, will be asked to allow a substantial appropriation for the purpose.

During the fair beginning September 7, the Indianapolis Automobile Trade Association will give a display of motor cars, parts and accessories. This will be held in a large tent and all of the space was taken several weeks ago.

Safety-First M. C. Co., a New Michigan Concern

SOUTH BEND, IND., Aug. 17—The Safety-First Motor Car Co., Kalamazoo, Mich., capitalized at $10,000, has filed articles of association with the secretary of state and is making plans for the manufacture of motor cars and trucks on a patent secured by Frank Dentler, of Vicksburg, Mich. The offices of the new concern are located at 210 Kalamazoo National Bank building, Kalamazoo. The officers of the company are: F. A. Young, president; W. P. Haines, vice-president; and George J. Haines, secretary and treasurer. It is the plan of the company to manufacture auto trucks, and automobiles and gasoline engines.

L-P-C Designer Attending Army Trucks

RACINE, WIS., Aug. 17—Wm. Mitchell Lewis of the L-P-C Motor Co., maker of the Lewis six has issued the following statement:

"M. Petard, our designer and chief engineer, being a native Son of France and a Captain in the Reserve Engineering Corps, has been ordered to report for duty; the Lewis Six, which M. Petard was testing out in the Alps, has been commandeered as the personal car of the Colonel of his regiment and the French yellow body has been painted a battleship grey.

"Petard was responsible for a large part of the engineering work on the motor trucks and tractors used by the French Army and it can readily be seen that his services to his country will be of tremendous importance. We had expected M. Petard to return to this country in September, but the duration of the war, if France is actively engaged, will represent the period of his absence. While we would like to have him with us, his work as designer and chief engineer has anticipated our requirements up to January 1, 1917, and all refinements to be incorporated in the Lewis Six for that period have already been thoroughly tested out."

"All Out for Elgin Races" with 32 Entries

Twenty-seven Cars Named for C. A. C. Trophy Next Friday—All for Free-for-All Saturday

CHICAGO, Aug. 17—Showing that the interest in racing is keener than ever and that the European war is not having any effect on the sport in this country, the Chicago Automobile Club to-day announced a record-breaking entry list for the fifth annual Elgin road races, which will be run off next Friday and Saturday.

Thirty-two cars for a total of fifty-nine entries are declared for the 2 days. On the first day, when the Chicago Automobile Club trophy will be contested for by cars of 450 cubic inches and under, twenty-seven are nominated, while in the free-for-all for the Elgin National trophy on the second day the full complement of thirty-one cars is billed to start. All cars are nominated for both days except the Lozier, Chadwick, one of the Whites, one of the Duesenbergs, a Rae and Burman special.

It is a most representative field, too, made up for the most part of private entries. The Stutz, Mercer and Maxwell really are the only factories directly represented. Others are backed by private owners, and Chicago is particularly strong in this respect, with nominations from Charles E. Erbstein, E. C. Patterson and Frederick Robinson. Frank Fox, of Indianapolis, is another of those who back racing cars for the love of the sport and not because of trade inclinations.

The thirty-two cars represent sixteen different entrants. Six foreign machines—three Peugeots, two Sunbeams and a Mercedes—are in the lot, while the White is a newcomer so far as Elgin is concerned. The complete entry list is as follows:

CAR	ENTRANT	DRIVER
Peugeot	E. J. Schroeder	Not named
Stutz	Stutz Motor Car Co	B. Oldfield
Stutz	Stutz Motor Car Co	G. Anderson
Sunbeam	W. Ziegler, Jr	H. Grant
Sunbeam	W. Ziegler, Jr	G. Morris
Peugeot	L. C. Erbes	R. Burman
Marmon	C. E. Erbstein	L. Heinemann
Stutz	W. Ziegler, Jr	F. H. Dearborn
Mercedes	E. C. Patterson	R. de Palma
Duesenberg	F. Duesenberg	E. Rickenbacher
Braender Bulldog	W. Chandler	W. Chandler
Duesenberg	Fred Duesenberg	Tom Alley
Pahys	F. Robinson	M. Roberts
Mercer	Mercer Automobile Co	S. Wishart
Mercer	Mercer Automobile Co	E. Pullen
Mercer	Ed Schillo	C. Luttrell
Gray Fox	Frank Fox	H. Wilcox
Peugeot	Peugeot Import Co	R. Mulford
Lozier	R. H. Knowles	L. Fontaine
Marmon	C. E. Erbstein	M. Stringer
Marmon	Moross Amusement Co	W. D'Alene
Maxwell	Moross Amusement Co	T. Tetzlaff
Maxwell	Moross Amusement Co	W. Carlson
Maxwell	Moross Amusement Co	Not named
Rae	Elmer Rae	Fritz Walker
Chadwick	Auto Service Corp	J. C. Hoskins
Duesenberg	F. E. Duesenberg	E. O'Donnell
Great Western	James Forsey	W. Tidmarsh
White	R. A. Bennett	W. J. Shrunk
White	R. A. Bennett	Eli Caillouette
Keeton		Callaghan
Burman Special		

Of these, it is known that the E. J. Schroeder Peugeot will not start. Schroeder was the first to enter and he was counting on de Palma driving for him. Then de Palma signed with Patterson, after which Schroeder abandoned all idea of coming to Elgin. No work has been done on the car since Indianapolis.

The Rae really is an old Mercedes rebuilt. It is of the vintage of 1903 and has been modernized by "Mercedes Fritz" Walker, who will drive the car himself. The Pahys is new, built by Frederick Robinson, a theatrical man who formerly was a locomotive engineer and who has introduced in it some of his own ideas.

The Elgin meet this year will differ from its predecessors in that the Pendleton system of scoring will be used, whereby the position of each car at each mile post will be posted. This has been used at Santa Monica for several years with great success. Then the system of starting two cars at a time, as in the French Grand Prix, will be used, which should add greatly to the interest in the races. The course is the same as before, and in each race the distance will be the same—301.65 miles. The prize fund totals $6,000, with $2,000 for first, $700 for second and $300 for third, with $200 purses for the fastest lap each day given by Harry Vissering, president of the Chicago Automobile Club, and Martin J. Kavanaugh.

On August 18, Spencer Wishart set a lap record while practising for the national road races. He circled the 8 1-2-mile course in 6 minutes 24 3-5 seconds, a rate of 79.8 miles an hour. The previous record was held by Tetzlaff who made it in 6:26.

Official practice started this morning with nearly every entrant at the course. The men will be given 2 hours each day. No practice will be allowed on Thursday. The races start at 11 o'clock each day.

White Dealers and Owners on Big Tour

CLEVELAND, O., Aug. 18—A tour which has all the elements of the old, familiar sociability run is being held this week and next by S. W. Forrester, the White dealer in Manhattan, Kan. The town has only 6000 inhabitants, but Forrester has found a good list of entrants in his tour.

The hundred or more motorists in about 25 cars started from Manhattan August 17 and were to reach Denver, Col., August 19. After four days of touring in the latter state the "motorcade" will return to Manhattan over the Santa Fe trail, arriving home August 27.

Forrester calls it the "Colorado White Tour." He began several weeks ago enlisting interest by a series of form letters, inviting White owners to participate. His letters were strongly and well worded, picturing the delights of Colorado and the joys to be found in the numerous camp-fire stops that will be made.

The pilot of the tour is Dr. Willhoit, of Manhattan, in a White 40 roadster. After touring Colorado 4 days and driving to Pueblo, the return trip will be made via La Junta and Lamar, the night stop being Garden City, Kan., a run of 231 miles. The next day's trip will include Dodge City, Great Bend and Lyons, ending at McPherson. August 27 the party will pass through Herrington and Junction City on the final run of 101 miles home.

Nearly every type of White gasoline car is represented. The first White sold in Kansas was entered by its Manhattan owner and is carrying a load of newspapermen. The vehicle has been running at least six years. To carry baggage and spare tires a White 1,500-pound delivery truck is accompanying the tourists. There is nothing to prevent a tourist's stopping at a hotel if he so desires, but the outdoor life has been made a feature of the run and roadside equipment is provided.

OAKLEY, KAN., Aug. 18—At the end of the first day all of the machines on the Colorado White Tour arrived in Hays, Kan., after a run of 184 miles from Manhattan on schedule and without any engine trouble whatever. There was a little tire trouble owing to the excessive heat in Kansas, but only a little time was taken out for the changes.

Seventeen White cars are in the tour at this time and a number will join before the tour reaches Denver. The roads in Kansas are ideal for touring. After passing Salina in the Golden Belt Route the roads are as hard as macadam, and recent rains have laid the dust.

Tetzlaff's Benz Goes ½ Mile in 12 3/5 Seconds

NEW YORK CITY, Aug. 18—On August 12 Teddy Tetzlaff drove the Blitzen Benz one-half mile straight away on the salt beds west of Salt Lake City in 12 3-5 seconds. The test was made to determine the speed qualities of the course. The salt beds are about 40 miles long and 20 miles wide. The surface is water level and does not vary one-half inch in 10 miles. The beds are much harder than ice and dynamite is used to blow holes in order to sink the telephone and telegraph poles across it. It is possible to survey a circular track of any distance up to 30 miles, either in a perfect circle or an oval shape.

Tetzlaff's record is not official because it was not sanctioned by the A. A. A.

Disbrow Lowers Mile and 2-Mile Track Records

NEW YORK CITY, Aug. 12—Louis Disbrow, in the Simplex Zip, on August 8 made a mile on a circular dirt track in St. Louis, Mo., in 45 1-5 seconds, one-fifth of a second below the world's record made by Oldfield at Bakersfield, Cal., April 27, 1913, in a Christie car. The 2-mile record on a dirt track, also made by Oldfield at Cleveland, O., on September 14, 1912, of 1:35 46-100, was also lowered by Disbrow, who negotiated the distance in 1:32 3-5.

These records have not as yet been accepted by the A. A. A., as the timing apparatus used at the meet has not been passed by the association. It will, however, test the apparatus at the coming Brighton Beach race on September 7. If it is passed by the contest board, these two records will stand as official.

NEW Cyclecar Firm for Wilmington.—The Cycle Car Co., Wilmington, Del., a corporation chartered under the laws of Delaware, is now in active business and expects to have its product ready for delivery to agents soon. The firm manufactures a cyclecar. The firm was incorporated by Marvel, Marvel & Wolcott, and T. C. Bradford, a well-known automobilist of Wilmington, is the salesmanager. The machines are to be manufactured there, which will be a distributing center for several states around. A complete electric equipment will be provided, with electric lights flashing both strong and dim. The gears are three speeds forward and one reverse. The rate of fuel consumption is estimated at between 30 and 40 miles per gallon, and the speed ranges from 3 to 55 miles per hour. The gasoline tank will be located under the cowl dash, with a capacity of eight gallons. Wheels are the Houk wire type. The four-cylinder motor generates from 16 to 20 horsepower. The shops are located at 224 French street. Already many inquiries have been made regarding the machine, and even orders, some from foreign countries, placed. The industry bids fair to be a complete success, and the advantages offered by the city of Wilmington as a distributing center are many.

Breen Co. to Add—The Breen Motor Co., Winnipeg, Man., plans to build an addition to its plant at Broadway and Sherbrooke street.

Portland Co. to Add—The Fiske Rubber Co., Portland, Ore., will begin work shortly on the construction of a three-story factory at Tenth and Burnside streets.

American Co. Buys Land—The American Motor Co. bought a 90 by 240-foot lot at Clearfield and Seventeenth streets, Philadelphia, Pa. It is said that a plant will be erected on the site.

Factory for Mount Vernon—Plans for a factory building on Pearl street, Mount Vernon, N. Y., to cost $20,000, are being completed by the Benford Mfg. Co., maker of spark plugs.

Midgley Installing Machinery — The Midgley Tire & Rubber Co., Lancaster, O., is installing machinery in its plant, and will commence operating at an early date. It is reported that additional power plant equipment will be required later on.

Umpton Co. Expanding — Umpton Automobile Co., Bristol, Ind., automobile springs, is looking over the field in La Porte, Ind., with a view of expanding its business and will try to interest the people in the company's stock; it proposes to also manufacture a light five-passenger car.

Independent Tire Again Busy—The Independent Tire Co., Guelph, Ont., has been taken over by a new board of directors, including President Reiner, of Wellesley; Frank Campbell, of Mitchell, and Mr. Dunn, of Strathroy. They open again with fifty hands and hope to double that number shortly.

Selling Pope Plant's Machinery—Colonel George Pope, receiver of the Pope Manufacturing Co., is selling off the machinery in small lots. The sale of several parcels was authorized recently by the judges of the superior court. The factory is to close down August 20, when all operations will stop.

Southern Co. Purchases Land — The Southern Automobile Co. has bought 10 acres of land in St. Bernard parish, New Orleans, La., from A. P. Perrin and will start the erection of what is to be the first automobile manufacturing plant in the South. The plant is to be completed the latter part of November.

Stearns Will Add Two Plants—The F. B. Stearns Co., manufacturer of automobiles, is having plans prepared for the erection of two factories in East Cleveland, O. One will be four stories, 70 by 157 feet; the other a five-story, 70 by 155 feet reinforced-concrete structure. The estimated cost of the buildings is $20,000.

Pierce Speed Controller Increases—The Pierce Speed Controller Co., Anderson, Ind., recently greatly increased its working force, having received some large orders from several concerns connected with the automobile business. One of the largest orders received was for 6,000 governors from the Continental Motor Mfg. Co., Detroit.

Plans Company Reorganization—Plans are being made at Coshocton, O., for a reorganization of the S. & M. Tire & Rubber Co., of that city. It is expected that the interests in the company held by Canton and Akron men will be taken over by Coshocton capital. A new plant is being equipped for the company and operations are to be started there soon.

New Automobile Industry—Prather Bros., Georgetown, Ky., have bought a large dwelling house there and will convert it into a demountable wheel factory. The Prathers have recently invented and patented an automobile wheel. They have sold 200 of their wheels to an automobile factory in Cincinnati.

Grant Plant Inspected—Recently the Grant Motor Co. invited the business men of Findlay, O., to visit its plant. A large number responded to the invitation, and under the direction of officers of the automobile company a thorough inspection of the premises was made and the various stages in the construction of a motor car explained to the visitors.

Eureka Co. Moves—The Eureka Auto Parts Mfg. Co., St. Louis, Mo., has moved into larger quarters at 1915 Pine street. The company, which manufactures the Eureka Diamond Honeycomb radiators and special coolers for the U. S. government, for use on tractors in the Panama Canal zone, has recently placed on the market a new V-shaped radiator for Ford cars.

Woodward Pump Co. Organized—The Woodward Pump Co., Detroit, Mich., has been organized here. Abishal Woodward is president; Edward L. Ackerman, vice-president; Clarence E. Blaesser, treasurer; Chester T. Fezzy, assistant-treasurer and Cornelius B. Woodward, secretary. Temporarily the offices are at 222 Third street. Pending the erection of a plant, the Joseph N. Smith Co., 22 Porter street, will make the pumps which are known under the trade name of "Impulsive Tire Pump."

The Automobile Calendar

Aug. 21-22	Chicago, Ill., Elgin Road Races, Chicago Automobile Club.
Aug.	Denver, Col., 650-mile Run, Colorado Springs to Salt Lake City.
Sept. 6-7-8	Newark, N. J., Cyclecar Reliability Tour to Atlantic City.
Sept. 7	Brighton Beach, N. Y., Track Meet, New York Motor Dealers' Contest Assn.
Sept. 7	Denver, Col., Track Race, Overland Park Track, Denver Motor Club.
Sept. 7-14	Indianapolis, Ind., Automobile Show, Indianapolis Automobile Trade Assn.
Sept. 9	Corona, Cal., Road Race, Corona Auto Assn.
Sept. 9-11	Convention Paving Brick Mfrs. Assn., Cleveland, O.
Sept. 10	Portsmouth, Eng., Autumn Conference, Institute of Metals.
Sept. 15-Oct. 11	New York City, Commercial Tercentenary Celebration.
Oct.	Philadelphia, Pa., E. V. A. A. Annual Convention.
Oct. 4	St. Louis, Mo., Automobile Show, Auto Manufacturers' and Dealers' Assn.
Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn.'s Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov.	El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 8-9	El Paso to Phoenix, Ariz., Automobile Race.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace.
Jan. 3-10	Buenos-Aires, Argentina, Grand Prize of Argentina.
Jan. 9-16	Philadelphia Automobile Show.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.

The Week in  the Industry

Motor Men in New Roles

TWO New Russell Appointments— It has just been announced that J. A. Martin, for the past 4 years manager of the Vancouver branch of the Russell Motor Car Co., Toronto, Ont., has been appointed salesmanager for Canada. When the Vancouver branch was organized Mr. Martin was chosen for the work of introducing the Russell car on the Pacific coast. He has been especially successful in opening up new ground and prefers the more strenuous work of organizing new territory. J. R. Marlow has been appointed manager of the Montreal branch. Mr. Marlow has been salesmanager of the Russell company until recently. During the past month Mr. Marlow went to Montreal to take charge of the business there for a short time. Both appointments date from August 1.

Holmes, Alma Salesmanager—M. J. Holmes has been appointed salesmanager of the Alma Motor Truck Co., Alma, Mich., builder of the Republic trucks.

Van Horne Studebaker Manager—The commercial vehicle department of the Studebaker Corp., Detroit, Mich., is now under the management of Charles Van Horne.

Howard Hupp Assistant Manager — W. C. Howard, who has been a traveling salesman for the Hupp Motor Car Co., Detroit, Mich., has been appointed to the position of assistant sales manager.

Walton Heads Champion Co.—A. R. Walton, formerly with the St. Louis Car Co., St. Louis, Mo., is at the head of the Champion Motor Car Co., 5200 N. Second street, which is building a four-cylinder car costing $800.

Myers Quits Stutz Job—W. D. Myers, for the past 3 years salesmanager of the Stutz Motor Car Co., Indianapolis, Ind., has resigned his position. It is expected that he will enter the retail end of the motor car business.

Cohen Joins Marmon—J. Groves Cohen, formerly with U. S. Motors and Locomobile, has joined the sales department of Nordyke & Marmon Co., Indianapolis, Ind., and will travel the South in the interest of the Marmon.

Brown Makes Change—H. W. Brown, formerly district representative of the Lozier Motor Co., Detroit, and for 3 years salesmanager for Don Lee, San Francisco, has become a member of the Frank Roueche Co., of Salt Lake City, Utah.

Stephenson Joins McFarlan—R. E. Stephenson has been appointed district representative for the McFarlan car and will make his headquarters in Indianapolis, Ind. Mr. Stephenson has been in the retail automobile business in Muncie, Ind., for several years past.

Buck Goes to Hupp—Charles E. Buck, formerly with the advertising department of the Peninsular Engraving Co., and also Detroit representative of the J. Walter Thompson Co., has been appointed assistant advertising manager of the Hupp Motor Car Co., Detroit, Mich.

Curtis Crow District Manager—L. H. Curtis, of Crisfield, Md., has been appointed by the Crow Motor Car Co., as district manager of the Crow-Elk-Hart line in the Philadelphia territory. The company's plant at Elkhart, Ind., is busily engaged in turning out its new 1915 models.

Root Succeeds Ashley—H. G. Root, Springfield, O., has purchased the stock held by H. L. Ashley, secretary-treasurer and general manager of the Westcott Motor Car Co., Richmond, Ind., and succeeds him September 1. Mr. Root has been engaged for many years in the automobile supply business in this city.

Kelly Now Studebaker Distributor—H. E. Kelly, of Oklahoma City, Okla., who for the past 4 years has been state representative of the Studebaker Corp. in Oklahoma, has resigned his position and organized the Kelly Motor Co., which will open offices in that city for the distribution of the Studebaker cars.

Dixon Resigns — A. Dixon, for several years past salesmanager of the McFarlan Motor Co., Connersville, Ind., has resigned to accept the position of district manager for the Krit Motor Car Co, and will make his headquarters at Omaha, Neb. Mr. Dixon will have charge of a wide territory covering several states, for the Krit company.

Light, Dixon Detroit Head—Oliver Light has been appointed general manager of the offices which the Joseph Dixon Crucible Co., Jersey City, N. J., has opened in Detroit and which are temporarily with the Boyer-Cambell Co., Congress and Brush streets. The Detroit management will look after the interests of the New Jersey company in the states of Michigan, Indiana and Ohio.

Scheu Resigns from Euclid—E. A. Scheu, president and general manager of the Euclid Motor Car Co., New York City, has tendered his resignation and severed all connections with the company. He disposed of his stock holdings and will have no interest whatsoever in the future of the company. Mr. Scheu intends to take a short vacation, and has made no announcement regarding his future plans.

Boldman, Standard Salesmanager—E. D. Boldman, during the last 6 years identified with different commercial vehicle manufacturers as their distributor in the East, has been appointed salesmanager for the eastern district, consisting of the states of Massachusetts, Rhode Island and Connecticut, for the Standard Motor Truck Co., Detroit, which has decided to appoint other district managers in different sections of the country.

Garage and Dealers' Field

Will Handle National—The Schreiber-Boorse Motor Car Co., Milwaukee, Wis., for the past 7 years distributor for the Locomobile, has closed a contract with the National Motor Vehicle Co., Indianapolis, Ind., to handle the National car in eastern Wisconsin.

Regal Added to Cartercar in Wisconsin—D. Wittenberg, owner of the Cartercar-Wisconsin Co., 2713 Grand avenue, Milwaukee, state agent for the Cartercar, has taken the agency for the Regal and to handle this department has organized a new corporation, the Regal Motor Co., with $5,000 capital.

Good Studebaker Sales Recorded — During the week ending June 20, R. L. Sutherland, Studebaker district representative for Indiana, reports that sixty-one Studebaker cars were sold out of Indianapolis, while during the following week the sales totaled close to sixty cars.

Reopell Buys Out Partner—A. V. Reopell has bought out his partner, W. L. Bunker, in what was formerly the Bunker & Reopell Co., Springfield, Mass., which had the agency for the Chevrolet cars. Mr. Reopell will continue the business. During the past season the former firm sold 54 Chevrolet cars in this city and vicinity.

Brown Tube's Winnipeg Office — The Brown Scientific Tube Co., the head office being at Longacre Building, Broadway, New York City, will open offices in Winnipeg at an early date. Senator Davis has control of the selling rights for Manitoba and Saskatchewan, and has appointed Mr. Murray as manager of the Winnipeg branch.

Ford Service in Madison, Wis.—A four-story Ford service building will be erected in Madison, Wis., state capital, by L. F. Schoelkopf, one of the first dealers in Madison and Ford agent for 7 years. Plans are being prepared for a fireproof building, 50 by 132 feet in size, four stories high, and when completed the Schoelkopf garage will be moved from 116 South Pinckney street to East Washington avenue.

Repairs Insisted Upon — The New Haven motorists have hit upon a good plan to insist on repairs being made in the city streets. Now when they see spots that are neglected, and which have been allowed to ravel away without any effort on the part of city officials to make repairs, the motorists get the local papers to take pictures and print stories showing the neglect, and this acts as a magical wand in changing conditions, for the officials do not relish public criticism backed up by photographic proofs.

New Reo Agents Appointed—The Capital Motor Car Co., Columbus, O., has been organized by Ira P. Madden and Ralph Atkinson, who are respectively president and general manager of the company, which has located at 168 North Fourth street, and which has the agency for the Reo cars for twelve counties, including Franklin county. The Reo Sales Co. and the Jeffery Distributing Co. have been organized in Salina, Kans., and Earl Hudkins is manager of both companies, which have the agency for the Reo and Jeffery cars.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

Canada

WINNIPEG—Canadian Bull Tractor Co.; capital, $1,000,000: to manufacture motor rucks. Incorporators: W. H. McWilliams, A. R. Argraft, J. S. Loudon, W. J. Cummings, Roy M. Wolbin, Walter Pace, L. A. Canon and H. P. Williams.

Illinois

CHICAGO—Service Motor Supply Co.; capital, $5,000; to deal in motor cars. Incorporators: Arthur J. J. Welsh, Gus. C. Aucutt, Samuel H. Silverman and H. F. Walbaum.

CHICAGO—North Side Buick Sales Co.; capital, $8,000; to deal in motor cars, accessories, etc. Incorporators: Henry Weil, Herman J. Rosenberg and Harry J. Lurie.

Indiana

ANDERSON—Simplex Sales Co.; capital, $12,000; to deal in motor cars. Incorporators: William H. Nelson, Eldred H. Wilford and Hattie A. Wheelock.

Iowa

WATERLOO—Dart Motor Truck Co.; under Delaware laws; capital, $600,000.

Kentucky

COVINGTON—Kenton Motors Co.; capital, $10,000. Incorporators: E. J. Rouse, L. E. Booth and M. R. Etheredge.

Louisiana

NEW ORLEANS—Eureka Water Motor Co.; capital, $10,000; to manufacture motors. Incorporators: J. B. Rochelle, E. J. Ernst and N. B. Ernst.

Missouri

LAWRENCEVILLE—Maxwell Motor Car Co.; capital, $200,000; to manufacture, buy, sell and repair motor cars. Incorporators: Andrew L. Maxwell, Casper L. Lewis and Noah M. Tehill.

New Jersey

PASSAIC—Passaic Auto Co.; capital, $1,000; to deal in motor cars. Incorporators: Chester R. Bates, M. K. Raymond and Chester L. Holloway, all of Passaic.

New Mexico

ROSWELL—Roswell Auto Co.; capital $50,000; general motor vehicle business. Incorporators: C. M. Farnsworth, C. C. Cagle and C. M. Sheperd, all of Roswell.

New York

DUNKIRK—Dunkirk Corporation; capital, $30,000; to manufacture mufflers, motors, engines, etc. Incorporators: E. Caldwell, E. K. Buttolph and R. J. Gross.

EDDYVILLE—Sanders Wilson Barnaby Co.; capital, $25,000; to deal in motor cars, etc. Incorporators: K. T. Barnaby, Newark, N. J., and others.

NEW YORK—Ventre & Ostruk; capital, $10,000; general motor car business. Incorporators, Henri Ventre, 250 West 54th street; Paul Ostruk, 1296 Avenue A; Joseph Schlesinger, 424 East 54th street.

YONKERS—Foster Motor Sales Co.; capital, $3,000. Incorporators: George B. Foster, Mary E. Foster and J. Bertram Foster, all of 84 Ludlow street.

Ohio

COLUMBUS—Capital Motor Car Co.; capital, $10,000; general motor vehicle business. Incorporators: Ira Madden, R. P. Atkinson and C. A. Yes.

Pennsylvania

PHILADELPHIA—Interstate Sales Co.; capital, $25,000; to manufacture and deal in motor cars, etc. Incorporators: W. C. Arnold, Lansdowne; H. G. Lansinger, Philadelphia; J. M. Satterfield, Dover.

Tennessee

NASHVILLE—Union Motor Co.; capital, $15,000; general motor vehicle business. Incorporators: E. Fisher Coles, Harding E. Jackson, R. C. Jones, Albert A. S. Britt and R. B. C. Howell.

Texas

HOUSTON—Emmert Machine & Auto Co.; capital, $5,000. Incorporators: Gus Emmert, Emil Emmert and C. G. Watson.

Wisconsin

MILWAUKEE—Regal Motor Co.; capital, $5,000; to deal in motor cars and accessories. Incorporators: D. Wittenberg, H. E. Legg and N. M. Wittenberg.

GARAGES AND ACCESSORIES

Connecticut

HARTFORD—Allen Bros. Garage; capital, $50,000.

California

SAN DIEGO—Owl Taxicab Co.; capital, $50,000. Incorporators: Herbert C. Guild, Horton L. Titus and E. L. Davin.

SAN FRANCISCO—Grand Pacific Garage Co.; capital, $20,000; to operate a garage. Incorporators: J. S. Adler, D. S. Cohn, J. J. Marx and H. Marx.

Delaware

DOVER—American Motor Utilities Co.; capital, $500,000; to manufacture Compton pneumatic starters and automatic control devices. Incorporators: J. McLaren, F. B. Knowlton and S. V. Dowling, all of New York City.

DOVER—International Motor Clubs Association; capital, $250,000; to furnish property protection to motorists. Incorporators: C. H. Butler, M. M. Hirons and L. B. Phillips, all of Dover.

Illinois

CHICAGO—United Electric Car Owners' Garages; capital, $50,000; to deal in motor cars, tires, etc., and operate garages. Incorporators: Sylvester C. Abbott, Dwight S. Bobb and E. P. Rumrill.

Indiana

EVANSVILLE—Benninghof-Nolan Co.; capital, $100,000; to deal in motor car supplies. Incorporators: Henry P. Benninghof, John J. Nolan and Val F. Nolan.

Kentucky

LOUISVILLE—Peerless Tire & Rubber Co.; capital, $10,000. Incorporators: A. F. Wolke, C. H. Wolke and Keith L. Bullitt.

Michigan

DETROIT—K.C.B. Co.; capital, $200,000; to manufacture a carbureter for heavy fuel. Incorporators: J. H. Chambers, C. H. Bennett and A. A. Leslie.

DETROIT—Michigan Lubricator Co.; capital, $200,000; to manufacture lubricators and other devices. Incorporators: John B. Corliss, John B. Corliss, Jr., and Cullen D. Corliss.

Missouri

ST. JOSEPH—National Spring Wheel Co.; capital, $100,000; to manufacture metal wheels for motor cars. Incorporators: W. L. Mann, W. P. Justice and E. J. Kearby.

North Carolina

WILMINGTON—Lassiter-McDuffie Co.; capital, $25,000. Incorporators: Clyde Lassiter, Neal O. McDuffie and Edwin T. Burton.

New Jersey

SOUTH ORANGE—Robinson Seitz Tire Co.; capital, $5,000; motor car tires. Incorporators: G. W. Robinson, A. M. Seitz and Frank Robinson, all of South Orange.

New York

BROOKLYN—Ellenbeck Tire & Supply Co.; capital, $5,000; to manufacture, deal in and repair tires, sundries, etc. Incorporators: William Ellenbeck, Jr., 44 Hancock street; Elmer H. Wilkinson and Elmer E. Wilkinson, both of 161 Underhill avenue.

ESOPUS—Kronenbergs & 77th Street Garage; capital, $1,000. Incorporators: Harris Weinstein, 92 Christie street, New York; Bertha Kronenberg and Bertha Kronenberg, both of 113 East 77th street, New York.

NEW ROCHELLE—C.B.A. Sales Co.; capital, $3,000; general garage business. Incorporators: Sidney H. Kent and William H. Schumacher, both of New Rochelle; M. J. Murphy, Brooklyn.

NEW YORK—Canada Carbide Sales Co.; capital, $10,000. Incorporators: Henry J. Fuller, Dongan Hills, S. I.; Douglas W. Dunn, Orange, N. J.; Walter L. Bush, West Brighton, N. Y.

NEW YORK—Pickens Auto Cloth Co.; capital, $1,000. Incorporators: Sale A. Pickens, 117 East 17th street; James W. Pickens, 5 West 65th street; Benjamin Simon, 17 East 101st street.

UTICA—Utica Garage Co.; capital, $1,500; to operate a garage. Incorporators: Paul Bartmer, 25 Plant street; Park T. Higgs, 1052 Elm street; Benjamin H. Dwinnel, Osborne avenue, New Hartford, N. Y.

Ohio

COLUMBUS—Ogden Fibre, Gear & Tire Co.; capital, $1,000; to manufacture and sell motor parts. Incorporators: D. Ogden, E. Ogden and Hubert S. Ogden.

Oklahoma

ENID—Oklahoma Auto Bus Co.; capital, $1,000. Incorporators: F. J. Gentry, Pond Creek; C. E. Pendleton and L. G. Pendleton, both of Enid.

Wisconsin

MILWAUKEE—The L-Arrow Auto Livery Co.; capital, $10,000; to operate a taxicab and motor livery service. Incorporators: Charles H. Ewe, William F. Albers and Charles W. Modersolm.

Changes of Name and Capital

Indiana

INDIANAPOLIS—National Motor Vehicle Co., from $250,000 to $600,000.

Ohio

CINCINNATI—United States Motor Truck Co., from $25,000 to $300,000.

CLEVELAND—Winton Motor Carriage Co. to Winton Motor Car Co.

Kentucky

COVINGTON—United States Motor Truck Co., from $250,000 to $300,000.

Accessories for the Automobilist

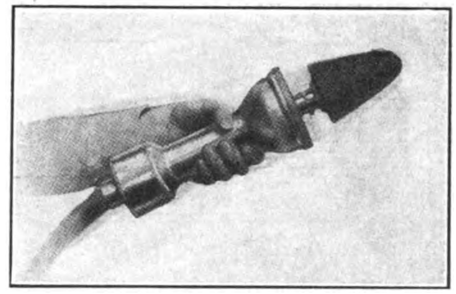

Fig. 5—Wizard car washer with a revolving brush propelled by the outflowing water

STEWART Hand Operated Horn—Five dollars is the price of a new hand operated horn, Fig. 1, just announced by the Stewart-Warner Speedometer Corp., Chicago, Ill.

The feature is the special double bracket for attaching it to the car. This supports the horn both in the middle and also at the rear end, so that any pressure on the sounding plunger is distributed between these two points, and therefore no looseness can develop.

This bracket, instead of being fastened directly to the car is mounted on an additional bracket, which is attached to the top rail of the car and conforms to the direction and design of the top rail. The two brackets are fastened by a swivel joint and thus can be turned in any direction desired.

Comfort Shock Absorbers—Front and rear shock absorbers for Ford cars are manufactured by the Comfort Shock Absorber Co., Hempstead, L. I. One of these is illustrated in Fig. 2. It will be noted that the device is designed for attachment to the spring ends and that two springs concentrically placed are employed in each unit. The advantage of this is that a better action is secured. Ordinarily the inner spring supports the load, but when the load increases the second spring comes into action.

A 30-days' free trial is offered and the guarantee is for life. The price per pair is $7.00 and four list at $12.50.

Tite-Wad Self-Locking Nut—The Empire Automatic Equipment Co., Syracuse, N. Y., is manufacturing the locknut illustrated in Fig. 3.

It is made in two parts only, the inner and outer sleeve, and by the peculiar spiral joint between these two members there is a cam-like action, the outer sleeve turning on the inner one, and locking the nut to the threads by friction.

National Standard Jacks—The Standard line of jacks, Fig. 4, manufactured by The National Standard Co., Niles, Mich., comprises all types. They are made for several lifting capacities and purposes, and lift either by ratchet mechanism or by screw arrangement. The latest type to be placed on the market by the Niles concern is the Standard tire saver and garage jack which is made primarily for quick action, and is preferably sold in sets of four so that the car may be completely lifted from the floor at its four corners, thus prolonging the life of the tires when the car is to stand for any length of time. Oily floors are in this way relieved of their menace.

The new National jack is made of malleable castings and the foot of the frame is of generous proportions to give needed support against tipping over. The lifting bar is enclosed and cannot fall apart when moved. Another point is that the teeth are placed close together, permitting of a wide range of action. The top of the lifting bar is swiveled, allowing for its being turned to any desired position. The jack may be readily adjusted to fit any size wheel from 30 to 42 inches in diameter.

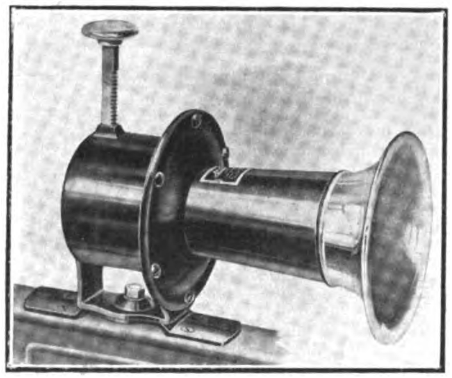

Fig. 1—New Stewart hand-operated horn

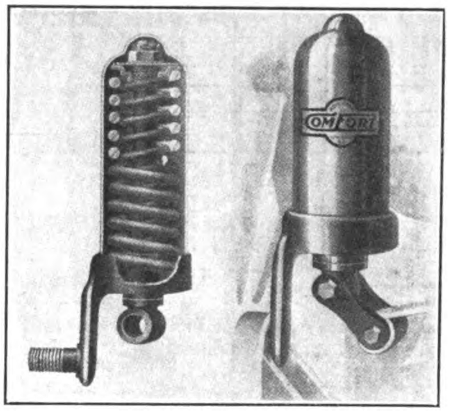

Fig. 2—Comfort shock absorbers for Fords

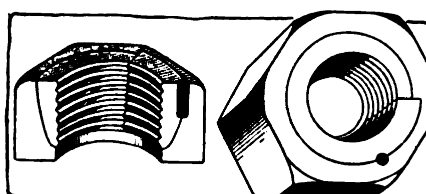

Fig. 3—Tite-Wad self-locking nut

The price for a set of four is $5.50.

The other jacks of Standard make range in lifting capacity from 1,500 to 2,000 pounds, and are thus adaptable to any car. One very good model, for instance, is the No. 1 Standard which is a 1-ton jack of the enclosed ratchet type and which has a height, with bar down, of 11 1-2 inches. With the lifting bar raised, this dimension is 18 inches. It weighs 9 1-2 pounds and lists at $4. This is suitable for the heaviest cars. The Baby Standard at $3 lifts 1,500 pounds, weighs 6 1-2 pounds and has a height with the bar down of 10 1-2 inches. Then there are several other styles.

For use with Fords or other light cars, a screw-type jack has been added to the line. This device, selling at $1, weighs 4 pounds and has a 6-inch lift.

The National company also makes a metal handle for jacks where it is necessary to lift large, heavy cars. These serve a double purpose, as they have a tire removing tool on one end. The length of these handles is regularly 15 inches, but for use with cars having a considerable overhang at the rear axle, they may be had 18 inches in length.

Wizard Car Washer—An improvement over the ordinary method of sponging cars in washing is claimed by the Century Foundry Co., Syracuse, N. Y., who has brought out a washer consisting of a combined nozzle and brush, Fig. 5. There are two brushes, both closely and smoothly shaved, one round like a sponge for use on flat surfaces, the other pointed for corners.

The feature of the new device is that it revolves at a speed of from 1,500 to 2,000 revolutions per minute, thus removing the mud and dirt instantly from

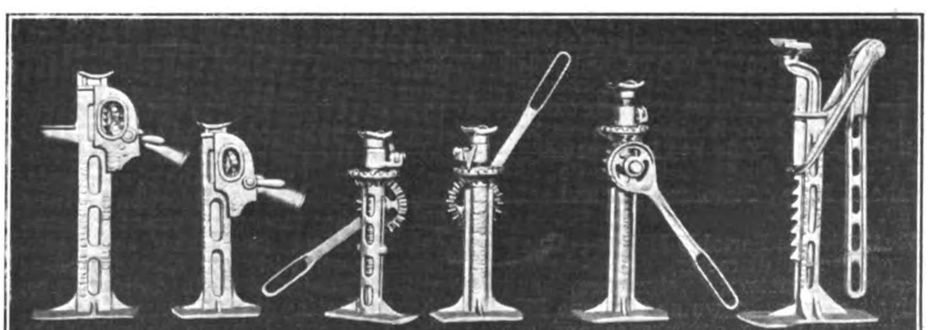

Fig. 4—National standard jacks of various types. The one at the extreme left is sold in sets of four and is to be used for saving the tires when the car is standing

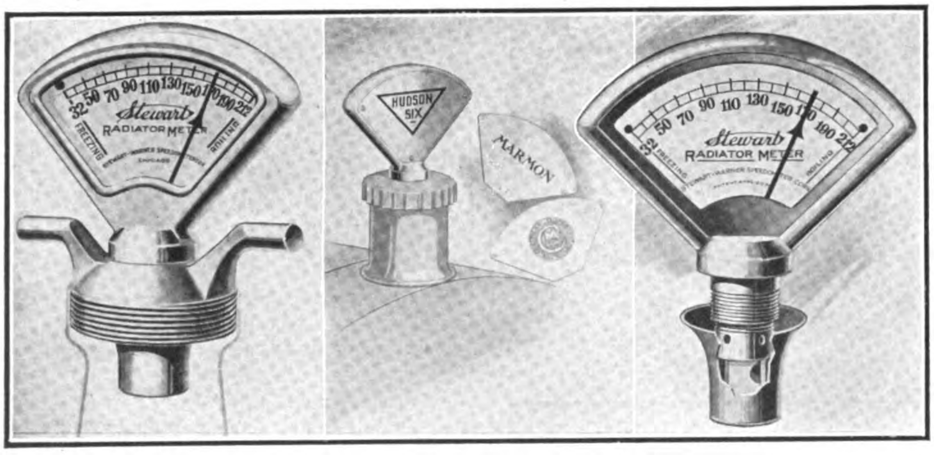

Fig. 6—Stewart radiator meters showing method of attaching the nameplate of the car to the back of the device. At the left is the combined radiator cap and meter for Fords

the most highly polished vehicle and yet it is claimed that no injury to the varnish is done for the reason that the brush runs inside a film of water which is thrown from the exhaust of the motor that propels the brush.

Stewart Radiator Meter—The special thermometer, Fig. 6, brought out for registering radiator temperatures a few months ago has recently been improved by adding a replica of the name-plate of the car to the reverse side. In addition a combined radiator meter and filler cap is now manufactured for Ford cars.

It is manufactured by the Stewart-Warner Speedometer Corp., Chicago, Ill.

Shanhouse Motorsuit—Many motor car owners will appreciate the garage suit made by W. Shanhouse & Sons, Rockford, Ill., and retailing at $2. This suit is similar to those used by racing car drivers while they are working about their cars. The suit is made of strong tan-colored material and covers the entire body.

Bryant Gearshift Lock—Fig. 7 shows a lock designed to prevent the theft of the car by locking the change gear lever in place. It consists of a pair of forks that slip down into the shifting slots and thus prevent the lever from being moved from neutral. The upper part of the mechanism, which contains the lock is clamped to the change lever and the lower part which carries the fork telescopes into it.

The clip which holds the upper half in place is bolted from the inside before the parts are telescoped together. The body is locked to the lever by a small ridge across the back wall of the body, which beds into a 1-8 groove, filed across the lever and the two parts are locked together by brass pins which are driven in and cannot be removed except by drilling. The locking of the car is the work of a moment. Simply kick or push down the stem and the forks of the lower end are forced into the gate on each side of the lever, and hold it rigidly in neutral until the proper Yale key is inserted.

It is made by the Bryant Sales Co., 422 Cuyahoga Bldg., Cleveland, O., and sells for $3.

Westinghouse Portable Meters—A new line of 5-inch diameter, direct-current portable ammeters, voltmeters, and millivolt meters, known as the type PW, has just made its appearance and are shown in Fig. 8.

These instruments are direct reading and suitable for battery testing, signal

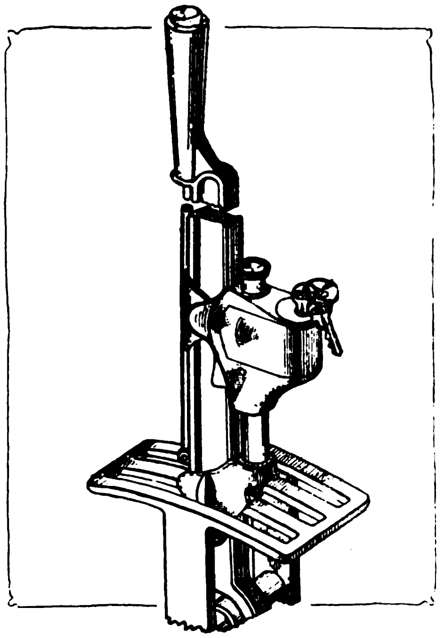

Fig. 7—Bryant gearshift lock to prevent theft of the car

work, and all purposes where an instrument of pocket size is desirable. They are particularly adapted to testing electric lighting and starting equipments of automobiles. They operate on the D'Arsonval principle, having a moving coil and a permanent magnet, which renders them free from residual errors.

The complete movement is mounted as a unit. A unique feature is the arrangement of the moving element which can be readily removed by taking off the cover and removing the two screws on the side pole-piece support. The entire moving element and the bearings can then be lifted out as a unit and can be replaced in exact position. This makes repairing possible without disturbing the alignment of the magnetic circuit.

Owing to the use of an aluminum pointer, a light counter-weight is sufficient, resulting in a light-weight movement and small wear on the pivot jewels. Their high torque in proportion to their light weight moving element insures great accuracy, considering their size. The meter will withstand shocks, such as it will be subjected to in ordinary use, without affecting the accuracy.

The light metal frame on which the moving coil is wound moves through the air-gap of the strong magnet and makes the reading inherently dead-beat. This very important feature enables readings to be taken quickly, and prevents violent fluctuations from injuring the pointer or the moving element.

The scale is made of metal and subtends an arc of 90 degrees, giving large open divisions which are uniform throughout.

The full length of the pointer shows on the dial, thus making the meter easy to read. Each meter is mounted in a morocco leather-covered wood case with the heavy bevelled glass over dials.

A new feature has been used on the meter terminals. The terminal stud has a V-shaped groove (see Figs. 3 and 4) into which the wire lead is inserted. The thumb nut then screws down on the lead, gripping it in close contact between the thumb nut and the two sides of the groove. This feature has not heretofore been used on meters of American make, it is stated.

These meters are manufactured by the Westinghouse Electric & Manufacturing Company.

Ford Sedan Body—A closed body, Fig. 9 of the sedan type is manufactured by the Storm Buggy Co., 129 East Center street, Fostoria, O., for Ford automobiles. It is designed to carry four or five people comfortably. Wide window spaces are a feature. The windows may be raised or lowered at will in the doors and back, and the front opens for ventilation and rain vision. It is stated that the body is cool in summer, due to the provision for ventilation, and yet is warm in winter and dry in rainy weather. The upholstering is deep, and is made of whipcord, curled hair and comfortable pillow springs. The rear and side windows are fitted with silk curtains.

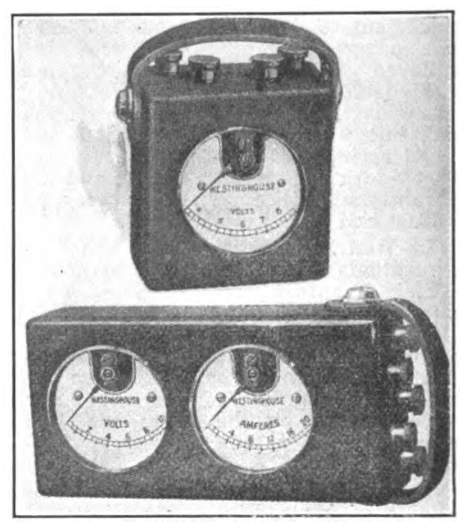

Fig. 8—Westinghouse portable meters. Top shows the voltmeter, while below is a combination of the volt and ammeter

Stutz Second on Friday, Mercer on Saturday — Wishart Killed on Saturday — Tires Make Wonderful Showing

CHICAGO, ILL., Aug. 24—Snatched from the jaws of war, the German Mercedes which Louis Wagner drove to second place in the French Grand Prix of 1914 was piloted to victory by Ralph De Palma, entered by E. C. Patterson of the Chicago Automobile Club, in the fifth annual road races at Elgin, Friday and Saturday of last week, winning the Chicago Automobile Club Cup and the Elgin National Trophy. The races were conducted by the Chicago Automobile Club and the Elgin Automobile Road Race Assn.

Records for the Course Broken

Previous records for the course were broken in both events, and on Friday it looked for a time as if a new world's record would be made, for Spencer Wishart was sending his Mercer around the course at 80 miles an hour with only eleven laps to go when a leaky gasoline tank brought him to a stop. De Palma's average for the Chicago Automobile Club Cup Race on Friday was 73.91 miles per hour for the 301.84 miles,

Anderson in Stutz finishing Friday's race just 44 seconds back of DePalma

as compared with Anderson's record of 71.5 miles per hour. On Saturday in the race for the Elgin National Trophy, he practically duplicated his performance of Friday by averaging 73.53 miles per hour for the same distance. The difference in time between Friday's and Saturday's races was only 1 minute and 17 seconds, both for the same distance.

But the brilliancy of this great road carnival is dimmed somewhat by the death of Spencer Wishart of the Mercer team, one of America's greatest drivers, who was killed in yesterday's race for the Elgin National Trophy at a time when it looked as if he would break his spell of bad luck.

A Crash at 100 Miles per Hour

Beaten the first day when his gasoline tank sprung a leak, Wishart started out Saturday to redeem himself. Always a front-runner, he soon opened a gap on the field which looked to be a safe one. He finished the thirteenth lap and started down the backstretch at a furious pace. A mile from McLean's turn at the northeast corner of the course, he overtook Henning in No. 26 Mercer. Immediately ahead of him was a culvert in a bend of the road and Wishart realized apparently that he would have to get there first.

Traveling at 100 miles an hour, he caught Henning, but in attempting to pass a rear hub cap hooked the front wheel of Henning's car. Wishart's Mercer immediately shot across the road in front of Henning, hit a post, ripped out 50 feet of fence, hit a tree and ricocheted to one side, turning over once, and finally turning turtle within 20 feet of the farmhouse. Wishart was still in the seat, but the car turning turtle threw him under the machine. The car had brushed into a crowd of spectators and injured

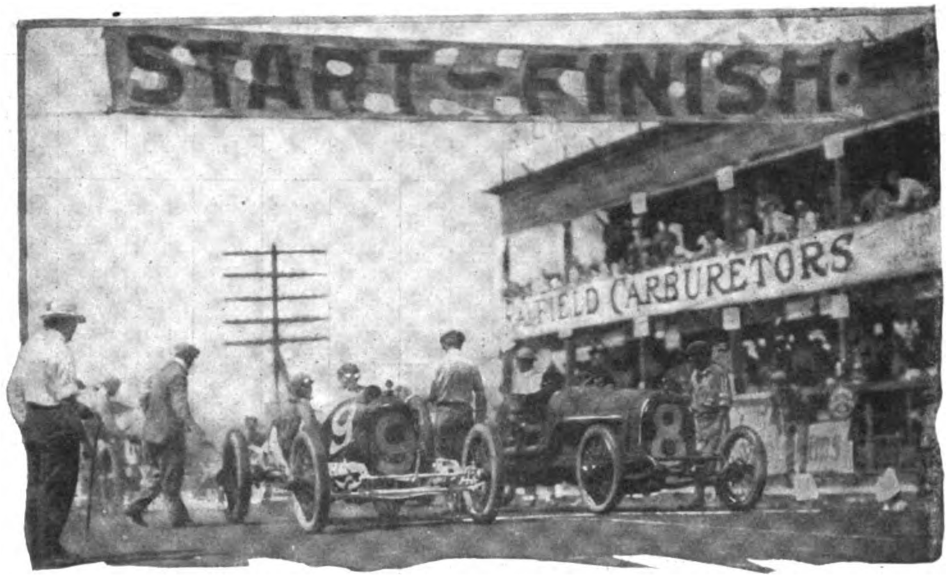
five of them. But the racing men were the greatest sufferers. His chest crushed, a leg broken, and injured internally, Wishart and his mechanic were rushed to the St. Joseph's hospital in Elgin but Wishart lived only long enough for Mrs. Wishart to reach his bedside. Jack Genter, the mechanic, was badly injured. He died on Wednesday morning, after having been despaired of by the physicians in charge.



Start of Saturday's race, showing how cars were started in pairs

Two-Car Start Works Well

From a racing viewpoint, though, the meet was a great success. On both days the attendance was a record breaker; the largest field of entries ever secured for an American road race started; the weather was of the best and the promoters will be able to show a fair profit.

The meet was remarkable for the introduction of the two-car start as used in the French Grand Prix and the Pendleton scoreboard made its eastern début. Both worked to perfection. Because of having twenty-eight starters the second day and twenty on the first day, the two-car start was a necessity. Starter Wagner sent the contestants away in pairs without a hitch, a broad white line from the tape to Hornbeek's turn making two lanes. Each car had to stay in its own lane for the first lap until the turn was reached, after which it was free to choose its way during the rest of the race, the idea being to insure a safe and orderly start.

The Pendleton scoreboard, designed by E. H. Pendleton of Los Angeles, Cal., recorded the exact position of each car at each mile of the course and as soon as a car finished a lap, the lap number also was posted. This information was secured by means of a telephone system around the course, one at each mile. Girl operators were used, each telephoning when a car passed her station. There was no hitch on either day.

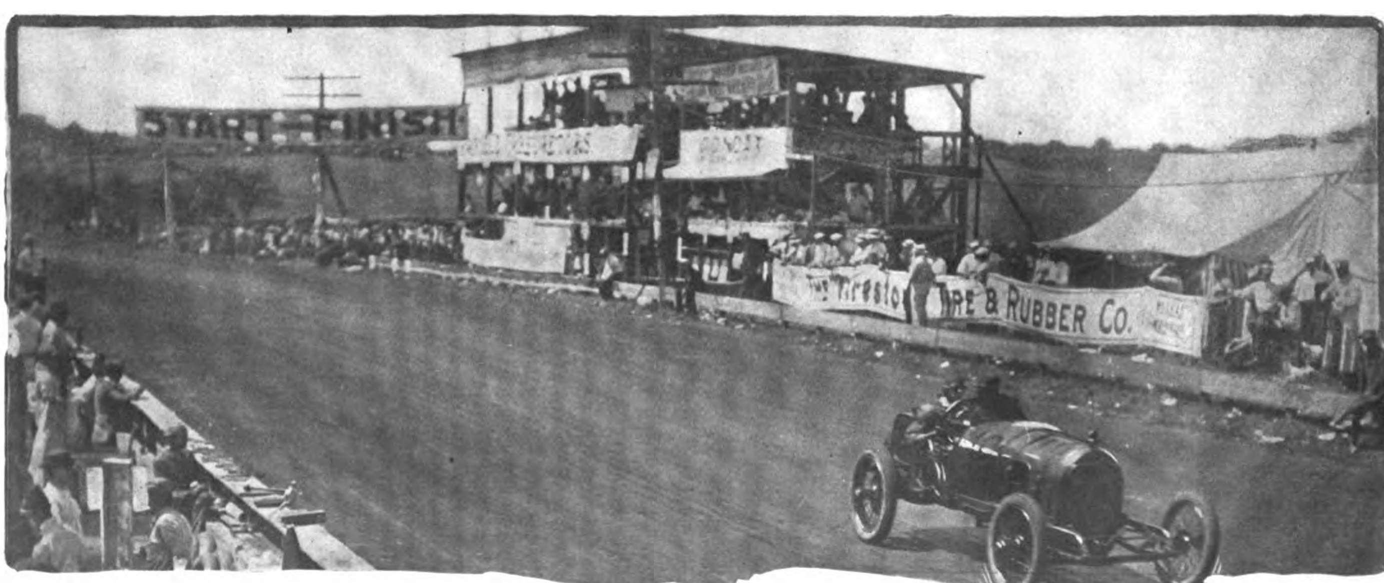
Wishart Takes the Lead

The first day's race for the Chicago Automobile Club trophy was for cars of 450 inches piston displacement and under. It brought to the tape twenty cars, Burman's Peugeot, Stringer's Marmon, D'Alene's Marmon, Callaghan's Keeton and No. 23 Maxwell being scratched. In this event Wishart was the dominating factor for twenty-five of the thirty-six laps. Gaining the front almost at the start, he had opened a gap of 9 minutes 40 seconds at the twenty-fifth lap when the vibration broke the support of the gasoline tank. His mechanic tried to hold the tank in place, but after a couple of laps Wishart gave up and retired.

This left it clear sailing for De Palma in the Mercedes and Anderson in the Stutz who settled down to a battle royal for the rest of the journey. It was a desperate fight, the lead fluctuating often. At the end, though, De Palma had the edge by 44 seconds but the last lap saw interest keyed up to the last notch, De Palma gaining the laurel wreath. The victor made only three stops. One was for supplies, a second was to change a tire in the backstretch and the third was to take on a new tire at the pits.

Anderson's Spares Caused His Defeat

Anderson's defeat was largely caused by delay in the backstretch when he stopped several minutes to pick up his two spare tires which broke loose from their moorings. Anderson feared that he would be disqualified unless he carried the spares, whereas this is not in the rules. Had he left the tires by the roadside and picked up new ones at the pits it might have been a different story.



Spencer Wishart in Mercer in Saturday's race finishing the thirteenth lap, when he was leading in the race just before his fatal accident

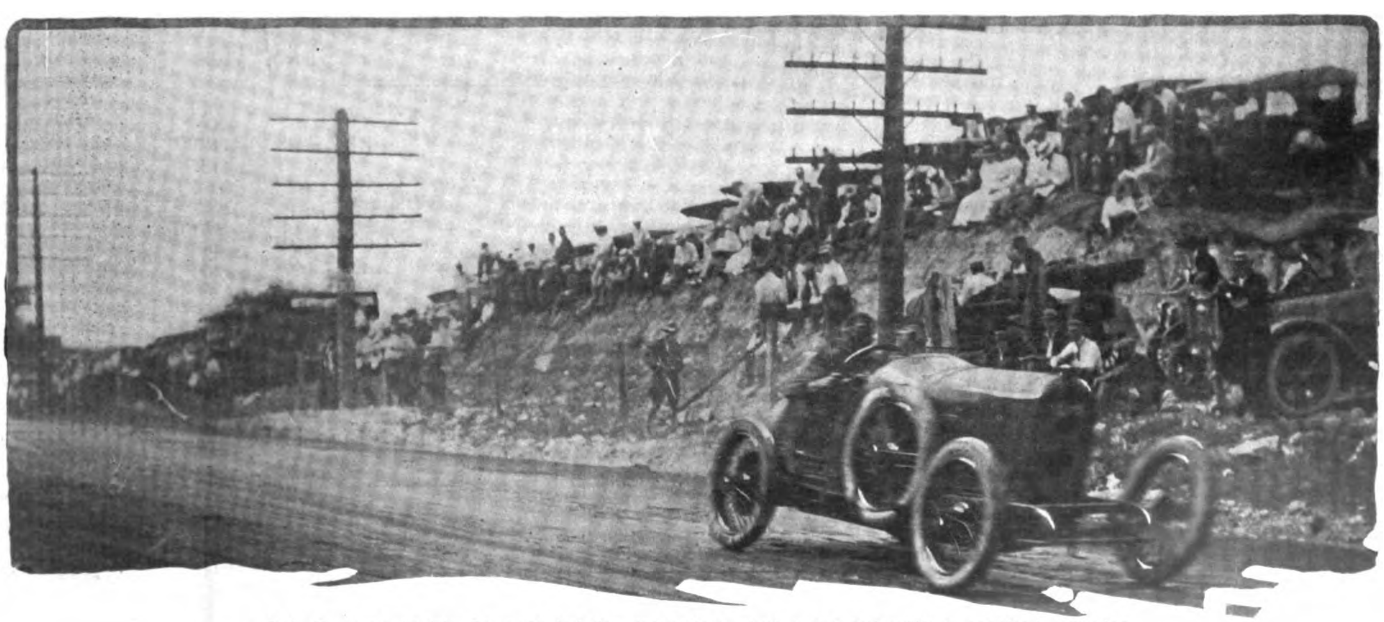
In this race seven were allowed to finish. Behind De Palma and Anderson came Mulford in the Boillot Peugeot, which ran into third place, less than 3 minutes behind the winner. Mulford had to nurse the car, for he finished with a cracked frame, evidently the result of the accident to Boillot at Indianapolis. Oldfield in a Stutz was fourth, Chandler in the Braender Bulldog fifth, Heinemann in a Marmon sixth and Dearborn in a Stutz seventh.

Although beaten by De Palma and the Mercedes, still the Stutz car has much to be proud of, for it made an enviable record. All three Stutz cars finished and the hood never was lifted on one of them. Anderson changed only one tire, while Oldfield and Dearborn, the latter driving the private entry of William Ziegler, went through without a single change of tire equipment.

Saturday's Race a Wonderful Battle

The race for the Elgin National Trophy the second day might well be classed as one of America's greatest road battles. In the first place it brought out the largest field that ever lined up before Starter Fred Wagner, and although it was slower throughout than the previous day's battle, still this was more than made up by the see-sawing of the leaders. As usual, Wishart went out in front but this time he did not open so big a gap, while thundering at his heels were Pullen in the Mercer, Burman in the Peugeot, Alley in the Duesenberg and De Palma in the Mercedes. The winner of Friday's race was back in the ruck for a considerable distance and it was the elimination of those in front of him that gave him his opportunity to become the winner of the 2 days' racing.

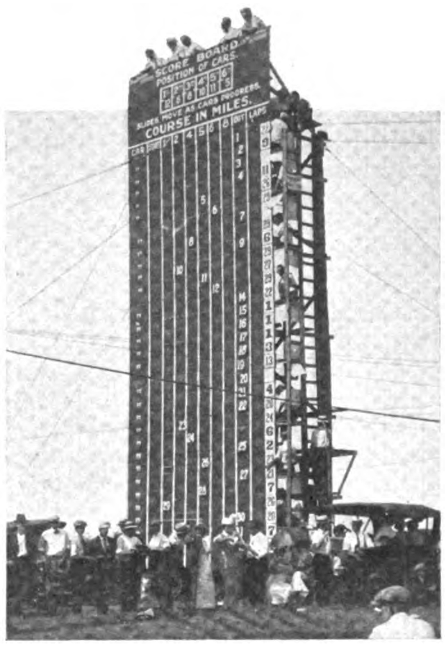


Bob Burman in his Peugeot led for many laps, but went out with a cracked cylinder

One of the eight telephone stations around the course which sent news of passing cars to the scoreboard

Wishart's accident gave those immediately behind him their chance and, following the fatal thirteenth lap, Burman in the Peugeot went into the lead. When Burman started in the morning he did not expect to be able to go more than a few laps because of the weak condition of the cylinder which cracked at Sioux City. But it held up surprisingly well and as long as it was in commission Burman was a factor. He blazed the way for the others for many laps, with Tom Alley in the Duesenberg and Pullen in the Mercer barking at his heels. Alley was particularly aggressive and brought his car up to within a few seconds of the Peugeot. Then Rickenbacher, who had been eliminated earlier, slid into the seat and he drove so furiously that he was the leader following a stop at the pits for supplies by Burman. A little later, though, a broken driveshaft stopped him and this left the way clear for DePalma, who with Pullen, had passed Burman when the latter stopped at the pits.

It was a ding-dong battle at this stage of the race. Any one of four cars could win. Burman, though, quit with only a lap and a half to go when the weak cylinder went wrong.



Pendleton scoreboard at grandstand. White numbers at right show number of laps each car made. Other numbers show the different cars and the eight vertical columns show their position around the course

Pullen's Sensational Fight

For the second time at the meet DePalma went into the last lap with only a slight advantage. Pullen, who went through the entire race without a stop, was dogging his heels, ready to take advantage of any slip and had a fighting chance all the way to the last lap. DePalma, however, maintained his advantage and went over the line with a margin of 1 minute and 10 seconds over Pullen. The performance of the latter driver was remarkable indeed. In a much smaller car than Wishart's he always was a factor and went through the entire race without a stop.

Third in this race was the veteran Barney Oldfield who was fourth in Friday's race and who was remarkably consistent in both events. Gaston Maurice in the Sunbeam ran fourth. Eddie Hearne in the Burman Special was the last to get the checkered flag, being placed fifth. Also running at the finish were Carlson in the Maxwell and Henning in the Mercer.

DePalma has driven in four of the five Elgin meets, starting first in 1911, when he drove a Simplex, failing to finish.

The fastest lap the first day was 6:11, a mark at which two tied—Wishart and Mulford. Hung up for this was a $200 purse given by Martin J. Kavanaugh of the Chicago Automobile Club. On the second day Wishart carried off the honor with 6:20 3-5, made on his second lap.

DePalma Wins $4,400

DePalma won $4,400 in all, $2,000 for each first and $400 from the Rudge-Whitworth company for using its wire wheels. Pullen gets $800, which includes the Rudge-Whitworth $100 for second place. Anderson lands $700 for second the first day; Mulford, third the first day, picks up $300 for first and divides the Kavanaugh prize. Oldfield won $300 for being third the second day. Wishart's winnings included the $200 for Saturday's fastest lap, given by Harry Vissoring, president of the Chicago Automobile Club.

The Winning of the C. A. C. Cup

The Battle Between DePalma and Anderson—A 44-Second Victory

IT is 11 o'clock on Friday and twenty cars are lined up in front of the expectant grandstand in ten rows of two each to battle for the Chicago Automobile Club Cup

Six cars that were nominated for the race have been withdrawn. Bob Burman is a spectator, his Peugeot having sustained a broken cylinder the day before. Mel Stringer, slated to drive the No. 7 Marmon, is in the pits with his arm in a sling and his car is in the garage, wrecked by a spill in practice. The No. 18 Marmon is another absentee, being ruled out by the technical committee because its piston displacement exceeded 450 cubic inches. No reason is given for the withdrawal of the No. 23 Maxwell and the No. 32 Keeton. The No. 33 Peugeot is far from the scene of the struggle, its owner, E. J. Schroeder, refusing to ship it from New York on hearing that DePalma would not drive it.

Bang—They're Off!

A bomb explodes in midair and twenty mechanicians are at the cranking handles of the cars. Exhausts pop petulantly and the smoke is blinding. Engines roar a challenge. Starter Wagner starts to toll off the seconds. Gears rattle. The crowd breaks out in a cheer as Dearborn and Tetzlaff are sent away. The second annual race for the Chicago Automobile Club Cup is on.

The Great Western, driven by Tidmarsh, fails to complete even one lap, engine trouble eliminating it before the motor is fairly warmed up to its task.

Mulford's Peugeot leads on corrected time, having reeled off the first 8.38 miles in 6 minutes and 27 seconds. Wishart's time is but 2 seconds slower. It is evident that all records for the Elgin course are to be shattered.

Wishart is a dangerous competitor, however, for the Mercer covers the second lap in 6 minutes 11 seconds.

Two cars are eliminated after making three laps, Rickenbacher docking the Duesenberg with a broken gearshift lever, and Grant, his trousers' legs covered with grease, abandoning the Sunbeam with a broken oil line.

Wishart leads DePalma by 2 minutes, and so close is the struggle that Anderson, in eighth place, is only 5 and a fraction minutes abaft the yellow pacemaker.

In the next five laps three more cars are eliminated, Tetzlaff's Maxwell, Pullen's Mercer and Maurice's Sunbeam.

The fourteenth lap proves disastrous for both Alley and Carlson. The Duesenberg is abandoned with transmission trouble, and a refractory motor results in the elimination of the Maxwell.

Otto Henning, driving the No. 26 Mercer, quits the race after covering twenty-two laps, encountering engine trouble. Wishart stops for a second time on the twenty-third lap to tighten the gasoline tank, which has been jolted loose. He loses only 1 minute and 10 seconds in making the repairs, and at the completion of 200 miles has a lead of more than 6 minutes on DePalma.

Engine trouble eliminates Roberts' Pahys on the twenty-fifth lap. On the same circuit DePalma blows a tire on the back stretch and stops twice, once at the side of the course to change casings and once at the pit to take on a spare.

Although leading by a wide margin, it can be seen that Wishart is in trouble. His gasoline tank is leaking badly as he passes the stands, and on his twenty-sixth lap he stops for more than 2 minutes in a futile endeavor to strap on the tank. One more circuit of the course and Wishart is forced to abandon the Mercer in disgust.

At the time of Wishart's withdrawal Anderson has passed DePalma, and with the Mercer no longer a contender, the Stutz is leading the Mercedes by 39 seconds. Mulford is in third place; Oldfield, fourth; Chandler, fifth; Heinemann, sixth, and Dearborn, seventh.

On the twenty-eighth lap DePalma cuts down Anderson's lead to 26 seconds, but on the next circuit of the course the Stutz driver more than makes up the ground lost and has an advantage of 1 minute 4 seconds when he crosses the tape. Anderson loses a minute changing a rear tire on the thirtieth lap, and with but six more laps to go is only 23 seconds in front of the desperately driving Italian.

DePalma to the Front

On the thirty-first lap DePalma passes Anderson and assumes a lead of 44 seconds. On the next lap he increases this to 52 seconds, but does not gain or lose a second on the thirty-third circuit. DePalma has a friction over a minute to spare at the completion of the thirty-fourth lap, but so desperately does Anderson drive the last 16 miles that DePalma gets the checkered flag only 44 seconds before the Stutz pilot finished the most gruelling race in the history of the Elgin speed carnival.

Capturing the Elgin National Trophy

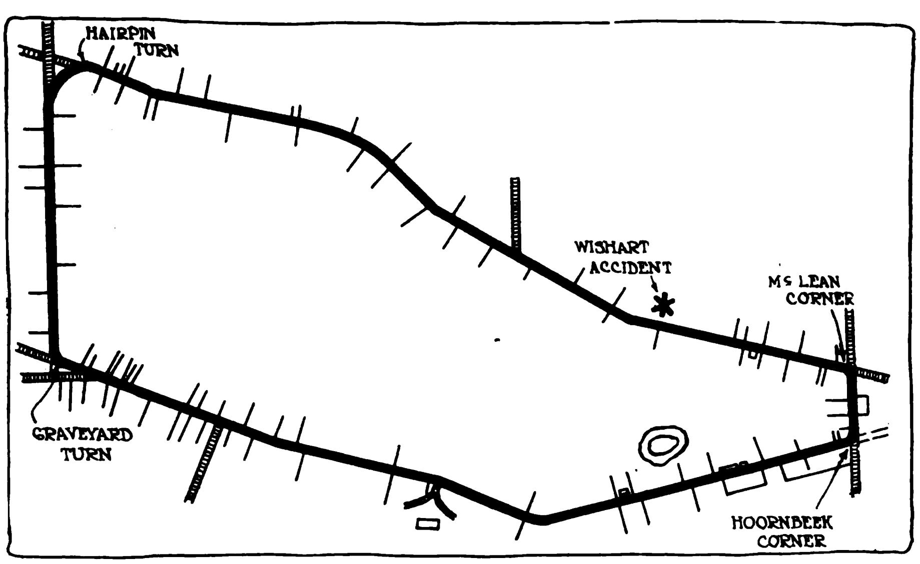
Wishart Was Leading Till 14th Lap —DePalma Wins Duel With Pullen

A HIATUS of 24 hours—a busy hiatus of tearing down and reassembling speed creations—and twenty-eight cars, the largest field that has ever faced a starter in an American road race, have answered the call of the clerk of the course and are awaiting the bomb that will start the struggle for the Elgin National Trophy.

Thirty-two cars originally were nominated, but four are missing—the No. 3 Duesenberg, the No. 7 Marmon, the No. 20 Peugeot and No. 23 Peugeot. Two, the Duesenberg and No. 20 Marmon, have spent their strength in the race of the day before and consequently will not start.

As on the previous day the cars are lined up in rows of two each and are sent away at 30-second intervals.

Wishart, forced out of the race of Friday with victory almost in his grasp, shows his car no mercy, and although running in eleventh position, is first on corrected time, having made the first 8.36 miles in 6 minutes 31 seconds. Burman takes 6 minutes 43 seconds to cover the initial lap and DePalma's Mercedes is only 1 second slower.



Map of the Elgin course on which Friday's and Saturday's races were run. Cross shows point at which Wishart's accident occurred

Fontaine, Burman, Dearborn and Pullen flash by the stands in the order named for a second time, but Wishart, traveling at a speed of 78.5 miles an hour, is announced as the leader.

On the third circuit of the course Burman passes Fontaine and moves up into the position of pacemaker, with Fontaine, Pullen, Dearborn and Rickenbacher taking his smoke. On corrected time Wishart is leading Anderson by 50 seconds and is driving like a madman to overtake and pass Burman.

On the fourth and fifth laps Burman is successful in throwing off Wishart's challenge. The Mercer is hanging onto the Peugeot with the tenacity of a bulldog, however, and it seems only a question of minutes un-

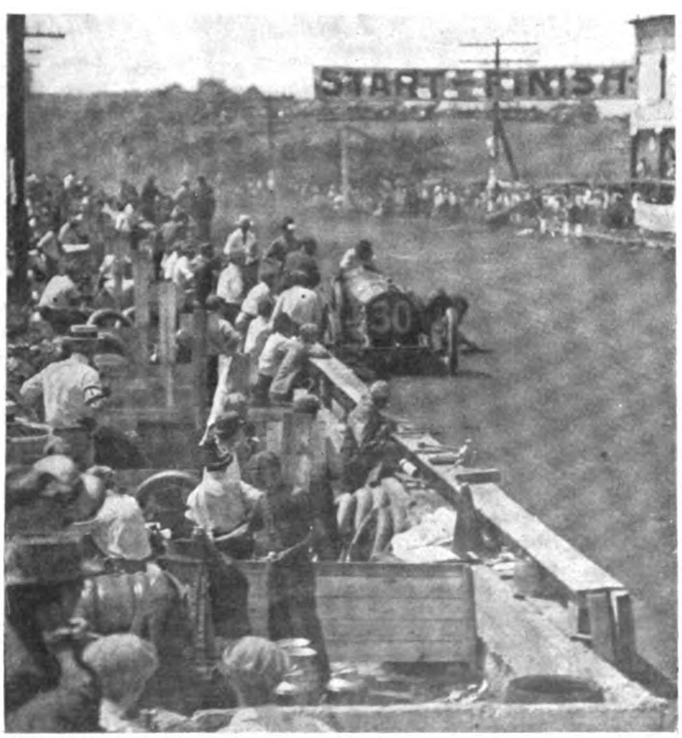
til it will pass the French car. Anderson, who is pushing Wishart, is forced to stop at the pit to repair a leaking radiator cap, and loses almost 4 minutes before he gets away again.

At the end of 50 miles Wishart has a lead of 1 minute 5 seconds on Burman and is driving at a rate of 75.1 miles an hour.

Eight cars have been eliminated at this stage of the struggle. Mercedes Fritz Walker has failed to complete one lap of the race and has docked his Rae with a broken clutch. A broken connecting-rod has retired Tidmarsh's Great Western on the second lap, and a broken radiator has disabled Luttrell's White. Engine trouble encountered on the third lap caused the retirement of Caillouette's White. D'Alene, in rounding Hornbeek's turn on the fourth lap, crashed into a tree and broke the frame and radiator of his Marmon. Mort Roberts abandoned the Pahys with a faulty motor on the fifth lap, and Orr voiced a similar complaint about his Maxwell on the next circuit of the course. Early in the race Callaghan was ordered out on account of the Keeton's bad brakes.

At the completion of twelve laps, or 100 miles, Wishart has



A scene at the pits on Saturday. Heinemann's Marmon making a tire change before the pits

increased his lead over Burman to 3 minutes and a fraction. Alley's Duesenberg is third; Pullen's Mercer, fourth; DePalma's Mercedes, fifth, and Grant's Sunbeam, sixth.

Five more cars were docked disabled before the 100-mile mark was reached. Rickenbacher's Duesenberg suffered from engine trouble on the seventh lap; the Chadwick was withdrawn because of engine trouble, and the Braender Bulldog caught on fire on the eighth lap; the Lozier broke a wheel on the tenth lap, and engine trouble eliminated Tetzlaff on the eleventh lap.

Burman Takes the Lead

The accident that cost Spencer Wishart his life on the fourteenth lap gives Burman an opportunity to take the lead once more, and at the completion of the eighteenth lap, or with the race half over, the speed king is leading by 1 minute 1 second, with Alley in the Duesenberg chasing him. Pullen in the Mercer is third and DePalma in the Mercedes is fourth, 5 minutes behind the new leader. A stop for gasoline and oil on the seventh lap, DePalma's only stop in the 301 miles, has cost him 55 seconds.

Anderson, a dangerous competitor early in the race, goes out on the twentieth lap, due to radiator trouble. Heinemann's Marmon is rolled to the grass with disabled brakes on the twenty-first lap and the Gray Fox, Grant's Sunbeam and Dearborn's Stutz are withdrawn on the twenty-third lap, all three cars suffering from balky motors.

Alley stops for fuel on his twentieth lap and is relieved by Rickenbacher, who steps on the throttle and sends the Duesenberg in pursuit of Burman.

Five times Rickenbacher passes the grandstand, gaining a few seconds on each lap. The distance between the Peugeot and Duesenberg is gradually and slowly cut down until at the end of the thirtieth lap Rickenbacher has passed Burman and is leading the closely bunched field by 1 minute 13 seconds.

DePalma and Pullen's Fight

Rickenbacher shows the way to the field for two more laps. With only 33 miles more to go, a driveshaft on the Duesenberg breaks and Rickenbacher and his mechanician walk to the pits, eliminated at the very dawn of their hour of triumph.

The withdrawal of Burman's Peugeot leaves DePalma and Pullen alone on the course to fight for the nerve-racking victory. At the start of the thirty-fifth lap DePalma has a lead of only 47 seconds on Pullen, who has not stopped once since he was sent away at 11 o'clock. The Italian has the faster car, however, and increases his lead to 55 seconds on the next to the last circuit. Pullen, after getting the green flag, urges the yellow Mercer to the limit of its speed, but the chase is a hopeless one and DePalma thunders over the line a victor by 1 minute 10 seconds.

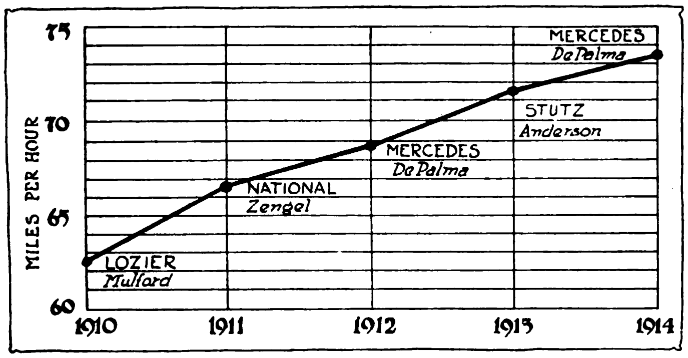


Chart showing the increase from year to year in the speed made in the Elgin National Trophy Race

Fast Team Work Lacking at Pits

Inadequate Preparation and Training of Crews Evident in Many Cases

THE 2 days of racing on the Elgin course were enlivened by eighty-eight pit stops. Forty-seven of these were made on Friday during the races for the trophy of the Chicago Automobile Club and forty-one on the following day. Out of these stops it was noticeable that a relatively small percentage were due to tire trouble as compared to other races. On the first day there were but sixteen stops for tires and on the second day, seventeen.

The fast team work at the pits which characterized the 500-mile Indianapolis race seemed to be lacking in the Elgin events. The tire changes were slow, even though demountable wheels were used and it did not seem as if the work of exchanging wheels had been sufficiently rehearsed. The Mercer, Stutz and Maxwell pits were exceptions to this rule, being manned by experienced crews.

Short Time at Pits by Some Cars

One of the features of the race was the short time spent at the pits by some of the cars. The three Stutzes all finished the race on the first day without having their bonnets lifted and the only tire changed by this team during that day was one on Anderson's car. Pullen ran his Mercer through the entire free-for-all without making a single stop.

Taking up the race on Friday for the Chicago Automobile Club Trophy, DePalma found it necessary to halt only three times in his 301-mile ride to victory. The total time lost at the pits was but 1 minute and 29 seconds. This was rather unexpected as it was the opinion of the railbirds that the winner would be held up at least 3 minutes at the pits, based on experience of former years.

Anderson Lost Needlessly

Anderson, who finished second, only 44 seconds behind DePalma, lost first place through the fact that he was not thoroughly familiar with the rules by which the race was governed. He lost a spare tire on the track and fearing to be disqualified he sent his mechanic back after the tire. This delay cost him 7 precious minutes during which time DePalma gained a lead.

The total time at the pits was 2 minutes 18 seconds but with 7 minutes lost on the back stretch the time stopped totaled 9 minutes 18 seconds.

Ralph Mulford in the Peugeot made three stops at the pits. This total stoppage at the pits was 4 minutes 54 seconds.

Barney Oldfield in the Stutz No. 11 halted only once in the 300 miles. This became necessary at the end of 160 miles when he stopped on the 19th lap for gasoline and oil. He was away in 1 minute 15 seconds. Oldfield did not change a tire during the event.

Chandler who drove his Braender Bulldog into fourth place made four stops at the pits changing seven tires and losing 10 minutes, 26 seconds in all at the pits. The pit work in Chandler's pit was very slow, particularly on the tire changes, and his running time could have been shortened quite considerably by some lively and heady work on the part of his assistants.

Heinemann in the number 30 Marmon who finished sixth lost considerable time at the pits, the chief trouble being the difficulty in keeping the spare tires tight.

He consumed 11 minutes 21 seconds at the pits in his five stops.

Stutz Drivers Did Not Lift Hoods

The Dearborn Stutz No. 1, which finished in seventh place, lost only 2 minutes, 31 seconds at the pits. Dearborn did not change a tire and, like the other Stutz drivers, never lifted the hood.

Wilcox's Gray Fox, which ran eighth, halted but three times, twice on account of valve trouble, the total time lost being 9 minutes 24 seconds.

Spencer Wishart, whose career was ended in the next day's event, was up in the lead for the first 190 miles but he was put out of the running by his gas tank becoming loosened by vibration. He lost considerable time trying to fix it up and finally withdrew in his 27th lap.

Pullen was well up for the first 10 laps until he went out on account of transmission trouble.

Pit Stops in Saturday's Race

DePalma made but one stop in the Saturday event and this was after he had gone 17 laps, taking 55 seconds to replenish his gasoline supply. DePalma changed no tires during the Free-for-all race and was riding on the same front tires that carried him through the event of the day before.

Pullen in the little Mercer holds the record for the 2-day's Elgin races as he was the only one to finish either day without making a stop of any kind. This he did Saturday.

Barney Oldfield halted at the pits five times but in none of them did he change a tire or lift the hood. All the stops were occasioned by taking on supplies of gasoline, oil and water, the last three being for water alone. His total time lost at the pits was 6 minutes 45 seconds.

Gaston Maurice, who piloted his Sunbeam to fourth place, stopped only once at the pits and this was to put a new spare on the rack to replace the one used on the tire change on the back stretch. He was away again in less than a minute and drove the final 140 miles without a halt.

The Burman Special with Eddie Hearne at the wheel drew up at the pits twice, both times to fill the gasoline and oil tanks and the radiator. The hood was not lifted at the pits and no tires were changed. The first stop occurred after 176 miles had been covered and the last one after 250 had been negotiated. His time lost at the pits was 2 minutes 55 seconds.

Carlson Has High Record for Stops

The Maxwell with Carlson at the wheel had only three laps to go when the finish flag put an end to the race. Carlson stopped more often than anyone else among the contenders. He stopped seven times in all and lost 12 minutes.

Bob Burman in the Peugeot had only two laps to go when he was put out on account of engine trouble. He had driven a very consistent race when he made only one stop at the pits. This was for gasoline and oil in the 32nd lap.

Wishart was in the lead in the number 19 Mercer when his fatal accident occurred in the 13th lap. He had not made a stop.

Anderson finished 19 laps without a stop when he was put out of the race with transmission trouble.

Rickenbacher went out in the sixth lap with a cracked cylinder and then drove the mount of his team-mate Alley until it went out with a broken drive shaft in the 32nd lap.

—

Tires Make Fine Record—Only 33 Stops on Two Days

UNPARALLELED in the history of the Elgin road races is the tire victory of this year's contests held last Friday and Saturday. Although in previous races the winning cars came through with comparatively few tire changes, this year shows a smaller number of tires per car than any other year, and the record stands above those made at Sioux City and other dirt courses in the country. Both contests this year showed a total of thirty-three tire changes and, with forty-eight cars on the course on both days, an average of less than a tire per car. Sioux City cannot boast of such a record, for in the 300-mile race just held twenty-one casings were replaced in the one race. Indianapolis, with its 500-mile classic, burned up more than $10,000 worth of tires in the race of last May.

Pullen's Remarkable Record

Some individual showings are of special interest. Barney Oldfield and Dearborn, both in Stutz cars, finished Friday's race without a single tire change, and on Saturday DePalma, the winner, not only went through without a change but used the same front tires which he used on the day previous. Oldfield and Dearborn used Firestone tires, and DePalma used Nassau casings. Still more remarkable than the showings mentioned is that of Ed. Pullen, who went through the entire race without a stop and without using his spare tire. Considering the heat of the day, the record speed and the condition of the course, the showing of Pullen, who rode on Silvertown cord tires, is to be compared only with that of Ralph Mulford's in the 1913 500-mile race. Mulford completed the grind driving a Mercedes, the heaviest car in the race, without making a single tire change. When compared with previous Elgin races this year's contests show a very low average per car for tires.

Tire Changes in Friday's Race

The first stop of the day for tires was made by Tom Alley who came in for a stop of more than 1 minute to change a right front.

Mulford came in again on his eighteenth lap with a tattered right rear which required 1 minute 30 seconds to replace, considerable time for a tire change when it is considered the record is something like 15 seconds.

In his 25th lap DePalma stopped at the pits for a spare tire, being his only change for the day. He was followed closely by Wishart who took on two spares which required 2 minutes 8 seconds and almost at the same time Mulford came in for a right rear. The last stop of the race for tires was made by Roberts in the Pahys who, after changing a right rear, discovered his gasoline tank was leaking and abandoned the race.

So, like the Sioux City race, the Elgin races showed that tire makers are not asleep and that speed contests have taught them much in the building of casings which can stand up under severe strains, heat and abrasion.

It was a victory of tires, but the work at the pits when it came to changing casings was indeed poor and the miserable performances at some of the pits was due directly to poor tool equipment and at others to inexperienced and excited attendants. In many cases a pitman with a jack in his hand and staring at a blown out casing would remain still until told by five simultaneous shouts that the right rear needed replacement.

Billy Chandler's crew seemed to be the only one which had quick-acting lifting jacks. The others had ordinary jacks.

Not one of the pit managers took advantage of the extra supply of casings on the back stretch on the second day. It was arranged that a supply of casings, watched by an attendant, could be placed on the back stretch and then there would be no need of stopping at the pits for a spare or if the spare had blown to run to the pits on the rim.

Oversight was evident. Road races call for strong supports for the extra tire, yet many of the cars came in front of the grandstand with the spare tire or wheel loose. The holding straps almost completely off in one case. In another instance the spare was lost on the back stretch because of insufficiently strong holding material. Charlie Erbstein warned his man before the race the leather straps were not strong enough. Mr. Erbstein may not be a prophet but he must be given credit for predicting the loss of Heinemann's extra casing.

One more correction might be made with regard to the method of approaching the pits for a tire change. It seemed that many drivers gave little thought to the fact that room is necessary to swing a wheel and not a few with a right front or rear to change came almost flush with the pits. This meant pushing the car to give the attendant a little room to get the wheel off and it also meant a great loss of time.

In both day's races few front tires had to be replaced, the greatest number of changes being necessary on right rears.

Faster Work on Saturday

On Saturday the first stop for tires came after the first lap when Carlson, driving one of the Maxwells, stopped at the pits to take on a spare, the original spare having been used to replace a blown-out casing.

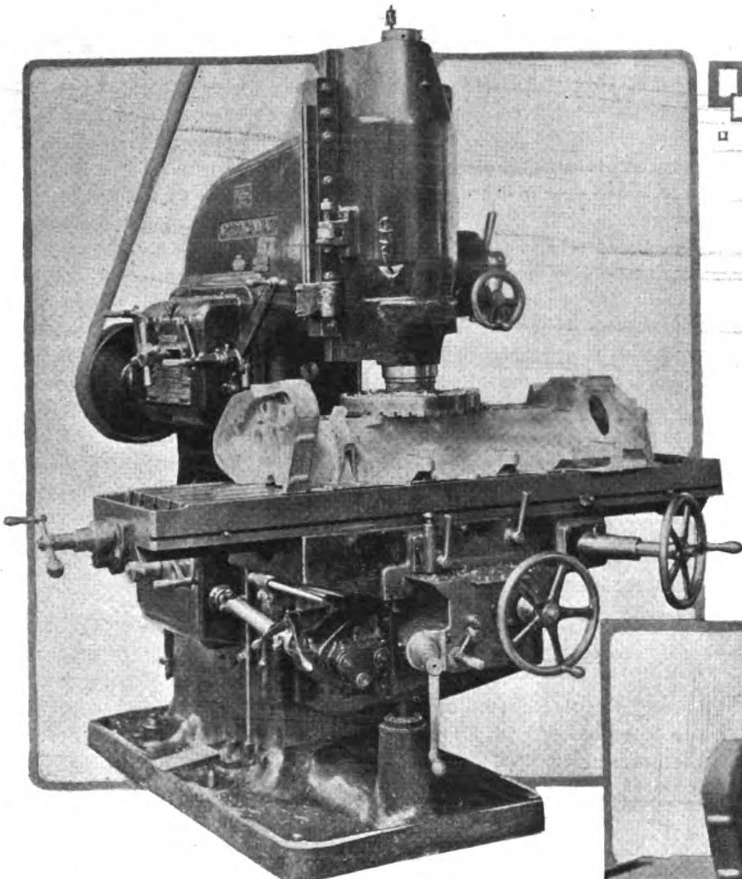
Tire changes at Chandler's pit were unusually fast, due primarily to pre-race training in spare and wheel-tire changes. Chandler's extra tire was taken on in less than 40 seconds and to bring out the speed of the whole crew, drivers changed positions, Mulford taking the wheel.

The last tire to be touched was the spare on Carlson's Maxwell which came loose at the end of the twenty-fifth lap and had to be tightened.

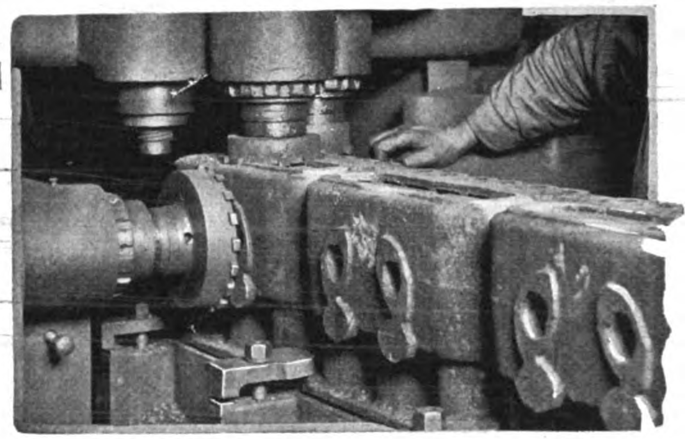
The Late Spencer Wishart

Spencer Wishart was 24 years old and had been racing since he was 18. His home town is Portchester, N. Y. He was married to Miss Louise McGowan, of Indianapolis, Ind., 2 months ago. He started by piloting cars owned by himself and finished second in the first race on the Indianapolis track. His work was a combination of daring and cool nerve, and soon he was called into the professional ranks and became the captain of a racing team for a manufacturer. On August 25, 1912, at Columbus, O., he broke the 75, 100, 150 and 200 mile track records. The first three are still standing. At the Santa Monica, Cal., races this spring he averaged 84.4 miles an hour before going out of the race. Funeral services were held on August 25 in New York City.

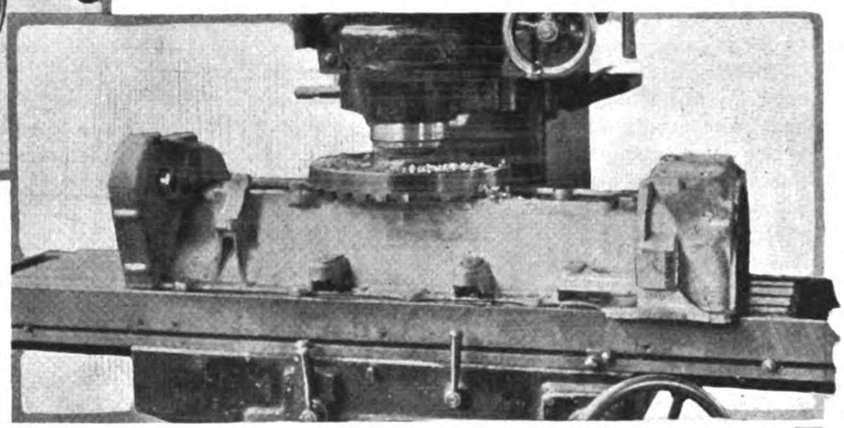
Cutter Life a Factor in Economy



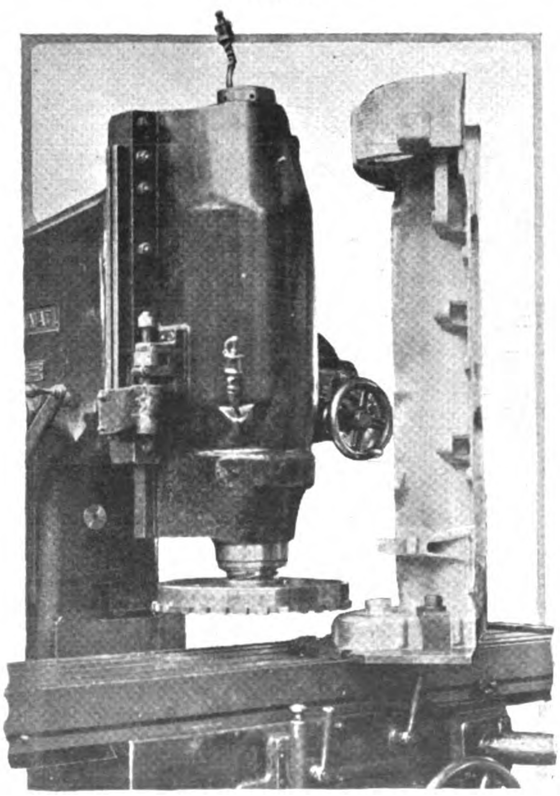
Tindel cutter milling a Continental six-cylinder crankcase



Cutters at work on the close-grain iron of Packard cylinders. The Packard Company states that, while the increased production has not appeared as a very great factor, owing to the close grain of the metal, the cutters last 20 to 25 per cent. longer without grinding



Milling the cylinder flange of a Continental six-cylinder crankcase



Milling the top and bottom faces of Continental crankcases

QUICK milling work is an essential feature in fast production methods in automobile plants. In the handling of cast iron it is desirable to have a fast feed on the machine and at the same time to have the life of the cutter as long as possible in order that the tool economy will be within the realms of reason.

The accompanying illustrations show the Tindel inserted tooth milling cutter in actual use in the plants of the Continental Motor Manufacturing Co. and the Packard Motor Car Co. In using these cutters in the Packard company's plant to mill very close-grained cast iron cylinders, the increased production has not appeared as a very great factor, but the Packard company states that it has found that the cutters stand up 20 to 25 per cent. longer without grinding.

Sometimes Table Feed Is 3.5 Inches per Minute

The table feed on the installation shown at the top right of this page is 2.5 inches per minute. The engineers of the Tindel-Norris company of Eddystone, Pa., makers of this machine, state that this can be easily exceeded and that there are cases where a 10-inch cutter is used to remove stock from cast iron with a rate of table feed of 3.5 inches per minute.

These tools operate on a semi-automatic principle and are thoroughly up to date as regards ease of handling. In the accompanying illustrations various steps in the milling of an aluminum crankcase are shown. The cylinder operation is for a Packard six.

Leaving Kretzy in the Russian military endurance trials, giving a good idea of the better class of roads in Russia

Russia—A Trade Opportunity

People Are Wary of Expense Attached to Ownership of Cars—Dealer is a Big Factor—Part II.

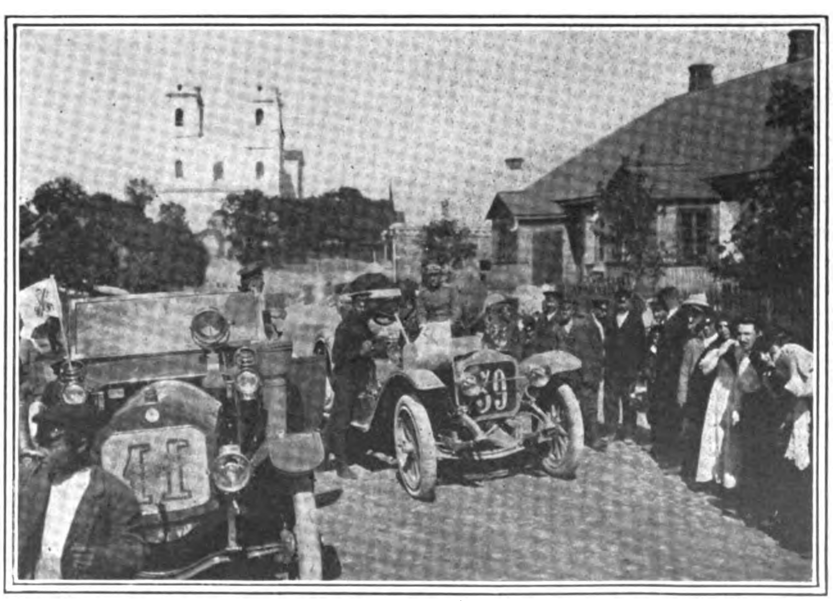
By the Late E. P. Batzell

¶ Editor's Note.—*This article was prepared some time ago by Mr. Batzell and so must be taken as a description of conditions in Russia at the outbreak of the great European war.* The Automobile *is indebted for the illustrations to The Autocar and to the White Company.*

THE character and the value of a car naturally put the owner in a certain class as to the service which he can reasonably expect and claim from the agent and from the car. On the other hand, it is so in reality that the richer parties buying more expensive cars can be made to pay for service without making them notice it and without scaring them away from becoming and continuing as automobile owners. It is that class of people who begin their automobile ownership at the medium- and low-priced cars who need most efforts and service to become cultivated into satisfied and permanent motorists. Many of them are attracted towards the pleasure they have in view when owning a car. Others would like to use their cars also for some commercial purpose. But, anticipating a big outlay for the upkeep of the car and the chauffeur, they all start with the purchase of a comparatively inexpensive machine, although under normal conditions they could and would have bought a much better and more costly one. They are not quite sure if they will remain automobile owners for long, their first machine taking the rôle of a trial one. Thus they gain knowledge and experience at the risk of the cheaper machine and consequently at the risk of little money, figuring correctly, that all expenses might be somewhat proportionally lower with a smaller price paid for at the time of first purchase. If this class of people is not getting the proper treatment and if they don't see their expectations come true more or less, the latter being largely out of the competence of the agent, they are lost customers to the dealer who sold them the first machine and they might become disappointed enough to leave motoring entirely, at least for a time, until, according to their expectations, the automobiles are further advanced and improved.

It is a fact that the few existing cheap makes of cars on the Russian market cannot boast of many repeated orders at the present when the owner would come back and dispose of his old machine to buy a new one of the same kind. The cases when such repeated orders have been taking place can be explained either by the cost of the particular machine being about all the owner really can pay, or that the use of the machine gives complete satisfaction. The latter generally happens very seldom if one uses it as a purely family machine; it is possible only if a commercial application is attached to it. The majority of automobilists who now buy the cheap grades of cars keep them only so long until they become more or less exacting as to features offered in them and until they obtain some automobile experience. Then they are prospects for better, more commodious and higher-priced machines.

Up to now the opportunity to try the use of an automobile with a limited outlay of money was very narrow on the Russian market, because one had hardly any choice of the cheap cars. Now their number and variety of types is gradually increasing, which means more competition between them



Part of third section of the Russian military trials stopping at Maljata

One of the cars in the Russian military trials on the road. Note poor road conditions

and consequently favors the buyer. That cheap cars are needed there can be readily seen from a few facts. The Ford has been practically the only type sold there since some years ago and which combines conventional automobile lines with a price much below that of medium European cars. Nevertheless now the lack of competition makes it possible there to sell a Ford touring car of the latest type for 2,375 rubles (about $1,200), because people are buying it anyhow, and one could not sell enough of them for a lower price to make the same profit because only 1,000 cars are sold yearly in the whole country. However, judging from statements at the Ford branch the above price is to be reduced for next year, which is caused either by a bigger allotment of cars to be sold or by increasing competition of the other cheap cars gradually making their appearance on that market. It is characteristic of the market conditions to note and compare the rate of sales of the Fords with the distribution of other much more expensive machines. In some districts there are more cars of some particular high-priced European make in one town than there are Fords in the whole district, the latter being bigger than a state. For example, the whole southwest of Russia with a populace of some 20,000,000 absorbs with difficulty 120 Fords in a year, whereas Laurin & Clement sell as many cars just around the city of Kief, in that same district. The latter city proper has some 500 automobiles registered, in which number are only about a dozen Fords. It is true, however, that the Ford branch there has existed but a short time.

Abnormal Prices the Rule

The sale of Fords is a good example, demonstrating how people are buying cars and paying abnormal prices for them, as long as they get a machine which is cheaper than another of much better grade. The big factor of price with new buyers also can be seen in the quite large rate of business carried on by the Cyclonette type of vehicle. This three-wheeler is very popular in Germany, where it originated, and in Russia. It has been much improved in recent years, having a four-cylinder, air-cooled motor exposed and set in front above the driving wheel. It seats four or five passengers, is considered as an automobile and, being cheap, has gained quite a field for city use. It is used for private purposes and also commercially, notably as a sort of taxicab.

Considering transportation charges and duty in bringing cars into Russia, one should make good profit there in selling the average $1,000 to $1,200 car for the price asked for the Ford now, or a little higher. Big business would be assured, although it could come only gradually. A car resembling the high-priced machines, and which combines good quality with attractive service terms for the owners, should bring many repeated orders among the class of medium rich people who can be satisfied and receive personal pleasure with an average car performance when there is not as much speed and luxury attached to it as in the better European cars of three times the price. To that class of people belongs the large mass of those who are no automobile prospects at the present, because they cannot afford to change cars quite often and stand much extra expense in that connection, but who would buy cars as soon as they are reasonably assured of their service ability without having to connect this feature with a high-priced car. Naturally, the efforts used to persuade them into buying cars are to be based on the evidence of favorable facts concerning the cars and their reputation among the users, which is very important.

Business Value Not Realized

The business man, the merchant, the doctor, etc., have not grasped as yet that the automobile is a contrivance not only for the pleasure of rich people, but that it can be used to a large part for their own business convenience. It seems that the European standard for the time factor in any transaction is to blame for the above. Things go much slower there and it is considered that a person is in haste if he rides in a hack. The cost of hiring or owning one of those is quite low, especially when securing one on a contract basis, for the daily needs of a doctor, contractor, etc. Although slow, the horse vehicle accomplishes its purpose satisfactorily, because the number of daily transactions and the distance to be traveled are generally much smaller than in the United States under the same conditions where an automobile would have been indispensable. Besides, the hired hack does not require any initial outlay, which is very important for the beginner in business, and it is free of the trouble one meets there in connection with the ownership of an automobile and with the chauffeur for the latter. People who are better off naturally own their horses and have hired drivers for them, but an outfit of good quality costs less than an automobile; the driver is not a privileged expert, but an ordinary peasant who is much easier ordered about than a chauffeur, and, most of all, one is not called upon by the fashion to change outfits every so often to keep pace with the rest, as in the case of automobiles.

Horse-Drawn Vehicles Predominate

At present in Russia one finds many instances of automobile use for business purposes, even heavy and light trucks, buses and delivery cars, aside from all those cars which are used by the government in many branches of civil and military activity. But their proportion to the horse-drawn vehicles of the same kind, except the buses, is very small. The large concerns which do much carting of heavy loads and where a number of trucks can be employed for this purpose are gradually introducing them. They are able to maintain a large garage and repair shop where proper expert management can be easily installed without making things too costly for the firm, as would be the case with smaller concerns with a small number of machines. The latter naturally would be putting greater responsibility on the shoulders of their drivers and are obliged to use the service of a public garage and repair shop for every piece of work requiring facilities and skill. Trucks are giving better satisfaction in the larger business enterprises and where they are accompanied by a service guarantee of a properly equipped selling agency. The lack of department stores and other large individual concerns which have much hauling to do is also a reason why the commercial vehicle does not spread rapidly in Russia. On the other hand, the advent of the automobile for bus service has practically begun this type of locomotion there. The horse-drawn buses never have been used, except as stage coaches between towns or between the hotels and the depots. Now the larger cities have one or more regular bus lines installed for competition with the street car systems and also separately. These lines appear to work out quite satisfactorily. They have also supplanted some of the formerly existing stage-coach lines for the transfer of passengers and freight between commercially connected towns when the available railroad facilities are not sufficient. In this respect the country is awakening to the possibilities of automobiles, the government setting the pace in all branches.

Reputations Grow Rapidly

The nature of the present gradual development of the automobile in Russia dictates some interesting points which it is valuable to keep in mind when going after business with the view of establishing a permanent undertaking there. The majority of present automobile owners and those who are the possible prospects of the near future for pleasure or commercial vehicles, as a general rule, are so situated that they come in contact with each other very easily, which is assisted by the many clubs of which they might be members or visitors. Very many owners and even prospects are sufficiently interested in cars, etc., to belong to the different local branches of the Imperial Automobile Club. The number of machines being limited as yet, the reputation of each individual make travels rapidly between this class of people and their acquaintances interested in automobiling. A person well known in automobile circles in Russia stated to the writer in this connection that any accident or mishap to a car in the south of Russia is very soon known in St. Petersburg and vice versa, thus taking a share in the establishing of a good or unfavorable reputation for the particular car all over the country.

Some makes are firmly established in the Russian market. The efforts required for the introduction of a new make of car can be best realized by actually observing them. It is considered good policy to select one's customers, not selling the car at random to everybody who wants to buy it until the machine has made a good reputation for itself.

Much influence upon public opinion can be derived from contests, which are being held every so often under the management of the different clubs and other organizations. The advertising value gained in winning a contest is very great, but at the same time the character of the contest and the list of entries should be looked into before taking part in it. It it better to abstain from entering it than to come out a bad loser, particularly if one has a new make on his hands, in which case one must be sure about the winning chances for it. There are cars which originally had a good business in Russia but are gradually dropping out of line, simply because they have made an unfavorable showing in contests.

Advertising Brings Good Results

Advertising in daily papers and in the two Russian magazines devoted to the automobile business brings good results. But the style of advertisement there is entirely different from the American style. Generally one does not say much, merely giving a few brief but convincing facts about the car and its record. A long advertisement or one written in boastful form will most surely displease the readers, who are all inclined to be sceptical in regard to any statement which is not strictly proven by facts at the same time. The public may have very little technical knowledge, but it has a highly developed literary sense. A few well and reservedly written facts are bound to attract attention. Short explanations of some of the meritorious mechanical points, run as a series, should satisfy those who are more or less mechanically inclined and who like to know something about the parts of a car before buying it, to which class belong practically all those who are interested enough to be subscribers of the trade papers. The distribution of advertisements among the different territories is best done through a central office, so that agents of one territory would not feel as if they carry the burden of cost for the benefit of the other fellow. That might be the case because people in the provinces very often read newspapers published in Moscow and St. Petersburg and the advertisements of the dealers in these two cities help a lot to the dealers in the province, for instance in southern, western and other parts of Russia. The cost of advertisements is much lower than in the United States, a dealer of a popular-priced car in Moscow spending only about $3,000 yearly for quite frequent publication in several daily papers there.

One of the steep hills encountered on the Russian military endurance run. Note the rolling character of the country

Thinks the Light Car Solves the Economy Problem

Engineer Finds that Public Favors the Light Car Type for Maximum Service Combined with Low Maintenance Cost — Principles of Light Car Design

By William B. Stout
Chief Engineer Scripps-Booth Co.

A car twice as big costs four times as much to run.

A car half as big has one-fourth of the surface and weighs only one-eighth as much.

A car twice as big weighs eight times as much.

LIGHT weight is the basis of low car cost and upkeep. Light axle weight is the basis of car comfort. Total weight has very little to do with comfort and the lighter the car the more comfortable it can be made, for the smaller the weight of the car in proportion to the rider's weight the less it can affect him. The weight of a mere man has little effect on a 400-pound rear axle under stiff springs.

The Tread-Wheelbase Ratio

A light car can hold the road as well as a big car. A short wheelbase car can be as comfortable and easy to steer as a long wheelbase limousine. This depends not on the wheelbase but on the ratio of tread to wheelbase. Any narrow tread car can negotiate even the worst of road conditions and the narrower the tread the better chance it has to pick a good track. The idea that the smoothest part of the road is in the ruts is erroneous. The ruts, as a rule, contain the biggest bumps and "thank-ye-ma'ms," and in bad places the wise driver of the big car spends his time dodging ruts, not trying to stay in them.

Much that has been believed regarding big cars and tread has been upset by the light car movement and the public can take a new attitude of mind towards road vehicles as a result.

Horse Set Tread Standard

The first motor cars were built horse size. Horses were a certain height and to drive them the seats had to be a certain height. To accommodate the height the tread of the wagon or carriage had to be a certain width, and hence the road standard of 56 inches. This is a horse standard.

When motor cars were built the idea was to make horseless carriages and these were first built with this idea in mind. The seats were buggy-high and buggy-wide and the wheels were large, as in buggy practice. The vehicles were in truth horseless carriages and fit for horse speeds. As speeds were increased it was found that the weights were too high in the air, and the wheels too high, and lower constructions were gotten up with weights better distributed.

At first engineers saw the advantage of the light car and many were built up and put on the market. Crest, Blood Bros., La Vigne, Orient, etc., etc., and yet the public, not yet wise on motor engineering, wanted something the size of Mrs. Croesus' brougham and big enough so that one wouldn't be looked down on. They refused to buy the light car. The motor buying public at that time was the rich man and the rich man's son and wife. These wanted, not a cheap light car, but a horseless carriage. To build a machine of this size took weight and power and road juggernauts were the result.

Since then the rich public has been supplied with cars. It has driven heavy cars and light cars and big cars and little cars; cars with two, four and six-cylinder motors; one-lungers, air-cooled cars and water cooled, friction driven and planetary, and the common people with them have come to know about the motor car and what each construction will do and will not do. They know the limitations of each construction, but only recently, since the moneyed buyer has been supplied with cars and the common people have begun to buy has the need for really light weight been insistent.

Light Car Economy

The people know that light weight means low upkeep and low first cost. They know that the particular light cars that have been sold in thousands as the only cars of this class are not ideal for everybody and they want a different car even at more money. Indeed, the great surprise of the light car movement has been that price was the smallest object; that is, the first price. The public wants a small car with dignity, refinement of line, luxurious finish, deep upholstery, high dust-proof sides, with the latest of everything in fitment and are willing to pay so the low upkeep be there. A car at $300 looking cheap will not sell in such quantities as a $600 car with the luxury and finish the public want.

A certain light car selling at about $500 offered an electric starter at $90 additional. Eighty per cent. of these cars are going out fitted with starters. The public wants the latest thing even in a light car and is willing to pay.

Every firm making light cars is having small difficulty with sales. The trouble is to make the cars fast enough. This is different from the cyclecar factories, nearly all of which have been disappointed in sales while surprised at road performance. The reason is not far to seek, when the simpler cyclecars are considered.

The public knows a water-cooled motor and is slow to be convinced of the V-type air-cooled even though it performs well. They know sliding gear and shaft drive, but are chary at first of belts and friction. They are willing to pay $100 more, even for a car of standard construction, to be sure they made a good buy rather than to pay less for a faster, easier-riding car perhaps, but about whose construction they know little.

Cyclecar Lessons Taught

The cyclecar movement, however, taught two things: first that there was a real road advantage, instead of a disadvantage, with a narrow tread; and second, that the light car could be as comfortable as a big car. They learned that the proportion of weights under and over the springs, not total weight, determined road comfort, that the proportion of tread to wheelbase determined the road performance of the car, not wheelbase alone.

The wonderful road work of some of the simple cyclecars with small motors was due to wheelbase tread proportions equivalent in some cases to 180-inch wheelbase on standard tread, and 80-pound axles under the springs instead of 400 pounds.

These discoveries are being made use of by several light car makers who are taking these ideas and fitting to them standard water-cooled motors, shaft drive and sliding gearsets, making them motor cars in every particular but with extra light axles, bevel or worm, and narrow tread. These cars stay with anything on the road and are very luxurious in their riding quality, while the light weight makes them easy to handle. There is a future for light cars of any tread, for tread of standard road width is of far less importance than is imagined, while narrow tread has advantages from every standpoint.

In building light cars the idea is to build a small motor car, a reduction in size of a big car.

Surfaces have two dimensions, volumes three. When you make a part of half size it has one-fourth the surface area and one-eighth the weight or volume. To make a car the same way reduces the weight in proportion. To halve the weight of a car, however, is to show one-fourth the upkeep expense, so one can see that the light car is enormously cheaper to run than a big car irrespective of price.

The Weight-Trimming Process

The small car of today is not a reduced big car, though that is the aim. To bring down size but retain the same tread, through the reduction of wheelbase makes the cars heavier riding than their big brothers, and does not allow of the light weight necessary. To hold the strain and twist of standard tread the axle weight is almost the same as in larger cars and the light car that is built on standard tread is strong enough for a four-passenger body. This capacity body has about four times the sales field of the two-passenger, which is a city machine, so that it is probable that the standard tread light car of the future will be a four-passenger job.

Cut Wheelbase and Tread

If one would make a minimum-weight car, which is a minimum upkeep and comfort car, the tread may be reduced in the same proportion as the wheelbase and thus retain for the new car the same road comfort of the big car that it is copied from. Without this reduction in tread in proportion there is a tendency to spin when one front wheel strikes a bump, which absorbs power continually though hardly noticeable to the driver. The lines of the big car cannot be retained, the long sweeping body lines that give the dignity desired, unless the car width is kept in proportion. Hence the possible tendency on two-passenger jobs toward narrower treads than standard. These are obtaining beautiful lines and appearance and the road quality of the best cars. They are country travelers as well as city vehicles, and are especially fitted to touring work.

One reason for their touring fitness is the ease with which they may be handled, some of them steering like a bicycle and being set very low to the ground. This nearness to the ground gives the driver and passengers a sense of safety not to be found in cars with high seats and allows of a higher average road speed under the same road conditions.

The light car of the future may very possibly do 50 miles per day more in touring than the average big car, largely on account of the lack of fatigue on the part of the driver, and due to the higher average speed.

In building a light car the writer believes in certain principles as necessary for real performance, one of these being narrow tread, to give a tread-wheelbase proportion of sufficient ratio, and the other light axle weight, especially rear axle.

The reason for the narrow tread has been outlined and can be well understood. It is a thing which cannot be explained as to its road performance wonders, but which one can readily appreciate after a 5-minute ride. The feeling of the narrow low car is different and very pleasing, with an entire absence of the danger sense, hence allowing greater speeds. That narrow tread can meet any road condition has been proved too many times to require further argument, and for two-passenger work the writer believes the narrow tread car to be the motor vehicle of the future, if not the four passenger.

Make Axles Light

Light axle weight is vital. When you reduce the size of a car you must reduce the axle weight in proportion, and the advantage of narrow light constructions is that the rear axle weight can be kept under 100 pounds, including wheels and tires, even with a shaft drive.

The springs of a car introduce a time element into a shock, making it a pressure rather than a blow. The stiffer the springs the greater the pressure, and the more resilient the springs the more comfortable a car can be. A heavy axle, however, needs a stiff spring to control it and keep it down on the road, or when it flies into the air over a bump it will take too long in getting back to the ground again. In other words, its trajectory is not shortened sufficiently. It takes a stiff spring to control a 400-pound standard rear axle in a big car.

With a light axle of 100 pounds a 50-pound deflection spring can control the weight easily and the time element, when small bumps are hit, is very short. A light axle car does not notice small bumps at all, such as running over rough cobble or crushed stone roads. Bigger bumps give the effect of striking a feather bed, the shocks are so distributed.

Another problem of the light car is the differential action. If one were asked the weakest point of the modern car an engineer would probably say the differential. If this is so in big cars it is more true in small cars where the differential gears are very small and correspondingly delicate. With the light car the weight needs distribution to obtain traction, and by using some form of differential, such as the new gearless types, which drive from both wheels this traction can be had and cheap construction as well with a solid rear axle shaft.

Requires Very Long Springs

The springs of a light car should be as long as those in a big car, for the road bumps met are the same size, and the car should show ability over the same roads. The light car can set a new standard of road comfort if these ideas are followed.

All of this is getting away from the horse-size idea, and horse tread, and by carrying the weight low on the new cars of narrow tread great stability is obtained with very little side throw. The seats are as near to the ground as comfort allows, the floor as low as consistent, and one can step from the running boards into the car at the same floor level, perhaps.

The light car is coming. It will be available in cheap construction and in luxurious elegance; it can be had with the latest mechanisms and with older tried-out but less efficient constructions at a lower price. It will be welcomed by cities and traffic police as taking less street space and moving faster and surer. The dawn of the light car era is at hand.—WILLIAM B. STOUT, Chief Engineer, Scripps-Booth Co.

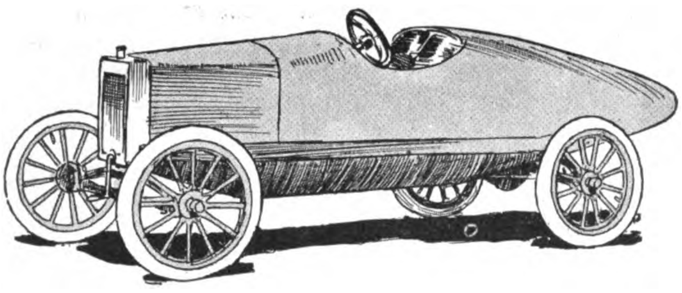

Fig. 1—Ford racer with streamline body and narrow aeroplane radiator

The Rostrum

How to Build a Ford Racer

EDITOR THE AUTOMOBILE:—I am planning to convert a new Ford chassis into a racing car. I want to make it as fast as possible and am willing to buy anything for it that will accomplish this end. It will not be used in races but on dirt country roads.

Macomb, Ill. EVERETT A. REXROAT.

—Increased speed may be obtained by reducing the wind resistance, carefully balancing the motor, lightening the reciprocating parts, changing the valve timing, advancing the spark and reducing the gear ratio between the motor and the rear wheels.

It probably will not be necessary to do all the things enumerated in order to get the speed you desire, unless you want the absolute maximum.

By cutting down the wind resistance and carefully balancing the parts the speed should be considerably increased probably to 60 miles per hour, although we have no figures.

If more speed is wanted, lighten the reciprocating parts and reduce the gear ratio.

Changing the timing or increasing the lift of the valves is not advised because of its expense, and you should be able to get sufficient speed without it. Furthermore, the motor probably would not stand the strain for any length of time that the new valve timing would permit, and even if it would it is doubtful whether the car would hold the road, due to the stiffness of the springs.

Lowering the wind resistance is a simple matter, and most important because the resistance offered by the wind increases as the cube of the speed. That is, the loss at 60 miles per hour to that at 20 is not triple but in the ratio of

$$\left(\frac{60}{20}\right)^3 = 3^3 = 27 \text{ times.}$$

A full streamline body, Fig. 1, with sweeping curves from front to rear may be used. The cost of construction should be under $200 if made by a body builder and less, of course, if you do the work yourself. If you have the body built, the exact cost will depend on whether any of the panels are spherically curved and require beating into shape. Where sheets of metal can be bent over the body framework without beating the cost is less. The latter type of body is the only one you could build yourself. The appearance of the car would be enhanced by employing a V-type Ford radiator or a narrow radiator such as is used on aeroplanes. As far as cooling is concerned the present radiator would be all right for short spurts but for continued running you would need to increase the capacity of the cooling system either by the use of a pump, a larger or higher speed fan, a larger radiator, or all three. The gasoline, oil and tires should be carried in the rear.

It would be simpler but almost as effective to fit two bucket seats to the floor of the chassis, and place the gasoline and oil tanks, and tires in the rear. Such a car is shown in Fig. 3.

It will be noted that the angle of inclination of the steering gear has been increased, in order that the driver can reach the wheel. This is done by forging a new steering gear bracket.

Bucket seats can be obtained at a cost of about $25 each from any body builder, and gasoline and oil tanks can be ordered through your supply dealer.

The fenders should be left off altogether, or else simple canvas ones fitted as shown.

Remove the pistons and connecting-rods and weigh the four rods and the four pistons. Then take off enough material from the heavier ones to bring them to the exact weight of the lightest.

If you want to lighten the pistons, drill below the wrist-pin. One-quarter-inch holes at a distance of one-half to three-quarters of an inch should be satisfactory. It is best to remove this material before the pistons are balanced.

Piston clearance should be increased except at the lower end. Make the top of the piston .005 of an inch smaller than the cylinder and taper off until the lower end is reached where the size remains the same.

The valve timing may be changed either by advancing the camshaft, or using a new camshaft with special cams that give increased lift and a longer opening, the latter is expensive however, because it costs money to make a camshaft. As already stated it is doubtful whether the motor would long stand the strain due to the increased speed that the motor would be capable of if this were done.

Advance the camshaft one tooth and note the result, then advance it another tooth and if the running of the motor is improved it may be found advisable to set it forward still another.

New Camshaft May Be Needed

If a new camshaft is made, the valves should open and close as follows: Intake opens, 20 degrees after upper dead center; and closes 50 degrees after lower dead center; exhaust opens 60 degrees before lower dead center and closes 15 degrees after upper dead center. It would also be advisable to increase the steepness of the cams to give a quicker opening and closing. Heavier valve springs will need to be fitted to hold the pushrods to the cams at high speed. The lift might also be increased to 5-16 or 3-8 inch.

The next size larger carbureter and a larger manifold might also be installed.

Sufficient lubrication is very important, and an auxiliary tank should be fitted so that oil may be injected directly into the crankcase, when running fast. Such a tank might be attached to the left side of the motor, allowing the oil to be fed by gravity through a pipe running into the crankcase, the rate of discharge being regulated by a plug cock that is controlled from the dash. Or you might place the oil tank in the rear of the car and feed by means of air pressure produced by a hand pump lying within easy reach of both driver and mechanic, when one is carried.

The gear ratio may be changed to about 3 to 1, although with the reciprocating parts of the motor perfectly balanced and lightened the car should do between 55 and 60 miles per hour anyway. The new gears will have to be made by some machinist, as the Ford company does not make any gears other than the standard ones which give a ratio of 3 7-11 to 1.

With the lighter body, the stiffness of the rear springs should be reduced. Try the car both with one and two leaves removed.

It must be remembered, however, that in increasing the speed of your car you are shortening its life. Furthermore, it will not run slowly on high gear if the suggested changes are made in the motor.

2—No steering gears are absolutely irreversible. One that would not give way when struck would soon break. It takes more force, however, to deflect the wheels with this type than an irreversible.

Formula for Long-Stroke Motors

Editor THE AUTOMOBILE:—Will you please give me the formula for figuring the horsepower of the long stroke motor for both four and six-cylinder motors?

Clinton, N. C. F. RAWLA.

—You might use the formula,

$$\text{h.p.} = \frac{D^2 N S R}{15{,}000}$$

where

D = bore in inches.
S = stroke in inches.
N = number of cylinders.
R = number of revolutions per minute.

This is not official; there is no formula that has been generally adopted that takes the stroke into consideration such as the S. A. E. formula which is based entirely on the bore and number of cylinders.

Effect of Tire Diameter on Differential

Editor THE AUTOMOBILE:—Recently I purchased a clincher tire stamped 32 by 4 inches. It measures 31 1-2 in. in diameter, and the cross-section is correspondingly skimpy. Would you advise using it on the rear with another tire, of different make, full 32? What effect will it have on the differential? The front tires are of different size, so it cannot be used there.

Milford, Conn. J. H. NETTLETON.

—This slight difference in tire size will not cause an appreciable amount of wear in the differential. Since it is only 1-2 inch in 32, the ratio is 1 to 64 and the percentage is 1.56. In other words the smaller tire will make 1.56 more revolutions in 100 than the larger one.

Speedometer Gear Makes Noise

Editor THE AUTOMOBILE:—1—There is a swishing sound issuing from the neighborhood of the right front wheel of my car when it is in motion. It seems to occur once every revolution. What do you think can be causing it?

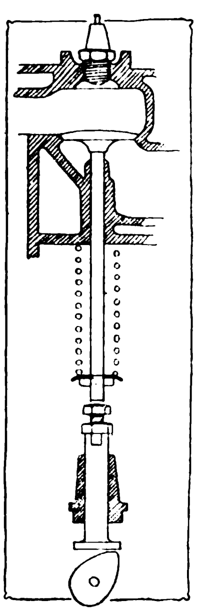

Fig. 2—Valve mechanism of typical motor

2—A short time ago I found that I could turn the front wheels of my car when it was standing on the garage floor by merely pulling on the tires, yet I thought that my steering gear was irreversible. What is the explanation?

Mt. Vernon, N. Y. E. W.

—1—There are two very likely causes of such a noise. It may be due to the speedometer gears meshing too tightly, or the demountable rim has a wedge loose. Jack up the wheel and rotate it slowly, and you can soon determine whether the gears are too close. If this is the case, loosen up the arm that carries the driven gear, and move the gear only far enough away so that the noise is eliminated. If the trouble is not found in the speedometer gears, tighten up the wedges on the rim. One loose wedge will make a noise similar to that you have described due to the lack of support at this point.

Valve Operation of Motor

Editor THE AUTOMOBILE:—1—Please publish a cut showing the valve system and all points of adjustment on the 1913 Regal underslung motor.

2—Also please inform me as to where I can obtain a transmission gear for a 1910 E. M. F.

Vineland, N. J. R. W. CALL.

—1—The complete valve mechanism is illustrated in Fig. 2—It consists of a cam, valve tappet, and valve together with its spring.

The valve opening is accomplished by the rotation of the cam which is part of the camshaft, which is driven by a

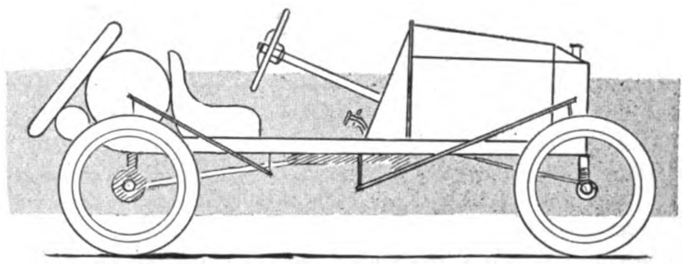

Fig. 3—Ford raceabout with pointed radiator

pair of gears from the crankshaft of the motor. This cam comes into contact with the mushroom face on the lower end of the tappet and the tappet is forced upward, its movement pushing the valve with it, and thus opening the port and allowing the gases to flow out. As the cam moves out of contact with the valve tappet, the spring on the valve forces the valve closed. When the valve is fully closed there is a slight amount of clearance between the valve stem and the top of the tappet and also between the lower end of the tappet and the circular surface of the cam.

The former space should be about the thickness of a piece of writing paper and as it is liable to change with wear, the tappet is adjustable. The upper end of the tappet has a hexagonal head, and screws into the lower half which is milled flat on two sides to provide a place for gripping with a wrench.

In addition there is a lock nut that holds the two parts securely in place. The adjustment is accomplished by loosening the locknut by turning it to the right, meanwhile the lower part of the tappet is held against rotation. Then the upper part of the tappet is turned while the lower part is held stationary, until the gap is the proper distance. Then the locknut is turned to the left again until tight.

The valve is removed by taking out the valve intake plug and then raising the valve spring seat by means of a tool that is made just for this purpose, then the key holding the spring seat in place is pulled out and the valve removed for grinding or inspection. In case it is desired to take the spring out this may be done with the fingers. The valve tappet and guide may be removed by unbolting the guide.

Standard Speedometer Shaft Revolves 1,680

Editor THE AUTOMOBILE:—Will you kindly tell me how many revolutions the link chain in a Standard speedometer makes during a steady run of 1 mile?

Indianapolis, Ind. I. P. ZIMMERMAN.

—The shaft of the Standard speedometer revolves 1,680 revolutions per mile, regardless of the diameter of the car wheels. This particular figure was selected because it gives a very simple method of figuring the number of teeth in the

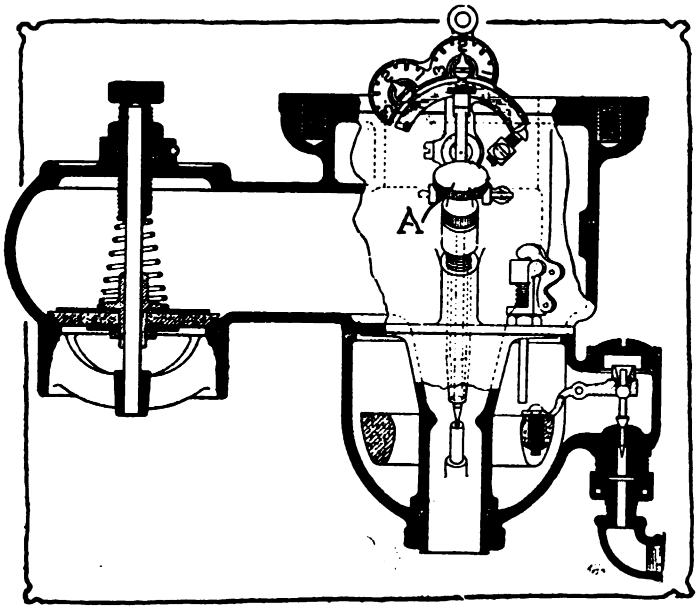

Fig. 4—Schebler model L carbureter

driving sprocket for a tire of a given size, namely, one tooth in the driving sprocket for each inch of tire diameter. A 12-inch wheel will revolve 1,680 times in traveling 1 mile. Therefore, if this wheel were attached to a 12-tooth driving sprocket which in turn drove a 12-tooth gear which was attached to the speedometer shaft, the ratio between the gears would be 1 to 1 and the speedometer shaft would make 1,680 revolutions per minute. If a 24-inch tire were used the wheel would make half as many revolutions per mile or 840. By using 24 teeth in the driving sprocket to drive 12 in the driven one the reduction is 2 to 1, and the speedometer shaft revolves 1,680 revolutions per mile just the same. With a 36-inch tire, 36 teeth would be used and this would give a ratio of 3 to 1, etc.

Cylinder Should Not Leak

Editor THE AUTOMOBILE:—Will you please tell me whether a cylinder should leak compression past the rings when stopped on dead center? If it should not leak, how do you remedy this?

2—Are the patented rings practical?

Westmount, Mont. W. H. HASKELL.

—1—The rings should be tight enough so that no appreciable loss of pressure will occur for, say, a minute, but it cannot be expected that the pressure will stay there indefinitely when the piston is stopped on dead center. From the way your question is worded it seems that you have turned the motor over until one of the pistons has reached the end of the compression stroke and that you left it there for a few moments, at least. If, however, we have misunderstood you, and the fact actually is that when you turn the motor over slowly without stopping, that the pressure decreases, then you have a leak. It may not be the fault of the rings, however, but due to the valves.

If the trouble is due to leaking rings they must be replaced and if the pistons and cylinders are very badly worn it may be necessary to bore out the cylinders and fit larger rings.

Before going to the trouble of tearing down the motor and examining the pistons and rings, remove the exhaust valve and note whether it is carbonized, or pitted. If so it must be ground. Also note whether there is any clearance between the valve stem and the push rod. (See Fig. 2.)

There should be sufficient space to insert a piece of writing paper, and if there is not the push rod must be adjusted by loosening the lock nut, which is the lower one and then turning the upper nut to the right. If there is no clearance the valve will be held off its seat and leakage will occur. If the exhaust valve is found to be in good condition, examine the inlet valve. It is not likely that it will need grinding although the push rod may be out of adjustment.

2—Some of the patented rings are satisfactory but whether they all are we cannot say with certainty because we have not seen them all in use.

Economy Record Is 86.6 Miles

Editor THE AUTOMOBILE:—Kindly advise me what carbureter holds the world's economy record on an automobile, and what is the number of miles?

Plainfield, N. J. PLAINFIELD AUTO TIRE CO.

—A Newcomb carbureter on a Franklin car undoubtedly holds the record for economy, the car having traveled 86.6 miles on 1 gallon of gasoline over Long Island roads, on June 21, 1913.

The car had a four-cylinder motor with a bore and stroke of 4 by 4 inches and without passengers weighed 1,690 pounds and with two passengers, 1,995 pounds.

Everything was done to reduce the coasting resistance of the car used in this trial for the record. Ball bearings were placed on the rear axle, a Newcomb carbureter fitted, the spring cut down so that there were but four blades in each half of the elliptic front and rear springs, the drive was taken through the springs and through one rear wheel, the other running free. One set of brakes, controlled by the hand, was used, 34 by 3.5-inch plain clincher tires pumped to a pressure of 35 pounds were fitted. The brake drums were even perforated to bring the weight to its absolute minimum. Wind resistance was cut down by using the streamline torpedo body, which carried a tapering cowl to cut the resistance.

Gasoline 63 Baumé

The gasoline used was 63 Beaumé test carried in a measured copper receptacle on the dash before the observer's seat. This was fed by gravity to the Newcomb carbureter which was standard except that the easy-starting, air shut-off valve was omitted. The odometer used was a Casgrain.

The course followed was on the Queens boulevard. The car traveled from the Williamsburg bridge out Queens boulevard to Hillside avenue, Jamaica, swinging left to the Jericho turnpike which was followed to the hamlet of Jericho where a turn was made across the island and then back over the same roads to the starting point. On the return to the starting point it was found that a little better than 60 miles had been covered and that some gasoline still remained. The remaining 20 miles was covered by a trip out Jackson avenue, and back and then another out the same route and nearly back to the starting point, so that the car went up practically every grade that it went down, although at times it seemed as if the car was fairly coasting up grade, so easily did it run.

Speed 14.5 Miles per Hour

Country passed through on the Franklin test was fairly level with an occasional 2 or 3 per cent. grade. The test lasted six hours, which makes an average speed over the entire distance of 14.5 miles per hour or regular touring speed. The driver would open his throttle until he had attained a speed of close to 20 miles an hour and then would stop the motor and coast.

It has always been a fascination to determine what mileage can be secured from a gallon of gasoline. A motorcycle has traveled 190 miles on 1 gallon and 10 ounces. This was done by S. A. Baker, September 13, 1907. The average accomplishments, however, of stock models with regular bodies fall far below these record tests. The average gasoline automobile travels from 15 to 20 miles on a gallon, although some touring cars go as low as 4 miles to the gallon and others as much as 28. The average steam automobile goes 10 miles to the gallon. The average aeroplane 10 miles to the gallon, but with its fuel mixed with lubricating oil. The average motorboat of corresponding horsepower to an automobile goes about 12 miles to the gallon, while a single-cylinder motorcycle will average better than 75. The strength of gasoline may be fully appreciated from the fact that it has been stated that could the entire energy contained in 1 pound be utilized it would lift a 1-pound weight 15,941,220 feet.

Rich Mixture Causes Leakage

Editor THE AUTOMOBILE:—Will you please tell me how to remedy the Schebler carbureter L on a 1913 Buick. When cranking, the gasoline flows out the air opening next to the pipe that carries the gasoline into the carbureter. At every crank the gasoline sputters out. It will not fire in the engine until all of the gasoline has sputtered out. All joints are tight. The float has been dried and shellacked. I can find no leak.

Madison, Ga. A. K. B.

—The needle valve, which controls the low-speed adjustment is open too far, allowing the fuel to flow out too freely. Screwing down on this valve should remedy the trouble. This valve is shown at A, Fig. 4, and should be turned down until the motor idles perfectly.

Formula of Calculating Water Capacity

Editor THE AUTOMOBILE:—Kindly publish a formula for figuring the amount of water needed to cool a gasoline motor.

2—Also a formula showing how to figure what size pipes are needed on a thermo-syphon motor.

St. Louis, Mo. V. C. KLOEPPER.

—1—The only data we know of on this subject is that represented in the curves shown in Fig. 5. With the piston displacement per minute known, the pounds of water required per minute and the B. T. Us. lost to the cooling water for any given range in cooling water temperature can be figured.

For example let us assume that the displacement per minute is 1,000 cubic feet and that the difference between the temperature of the incoming and outgoing water is 50 degrees. Reading vertically from 1,000 cubic feet per minute piston displacement, to the B. T. U. curve, proceed horizontally to the left until the diagonal representing 50 degrees range is reached. The vertical line through this point represents a flow of about 115 pounds of water per minute and the heat loss to the cooling water is shown by the horizontal line which indicates that the loss is about 6,400 B. T. Us.

2—No formula, as far as we know, has ever been published giving the size of pipe needed. In fact, it is difficult to see how a formula, that would give any more than a general idea, could be constructed unless, all types of motors, equipped with all shapes of pipes, types and sizes of radiators, and fans were tested out and constants for a general formula thus determined. It is seen that the factors that may be varied are so numerous that there are innumerable combinations, each one of which will give a different result and require a different size of pipe.

If you are designing a motor and want to know what size nipes to use, it would be best to find out the dimensions of the pipes on the successful motor that it resembles most, and make your pipes the same size. If it is found, after the motor is built, that the pipes are too small use a larger fan or increase its speed, or fit a larger radiator.

Car Jerks; Motor Fires Well

Editor THE AUTOMOBILE:—I have a 1912 second-hand Buick roadster which has a jerk which local mechanics have failed to locate or remedy. I have recently ground the valves; have put new platinum points in the magneto and the motor is firing perfectly, but there is a jerk, usually regular, which resembles the actions of a car when one cylinder is completely misfiring. The rear axle is slightly sprung and this might cause some of the jerking, but many times I can throttle the car down with cut-out open and it will run along smoothly for a block or so and then will start to jerking. There is some play in the universal joint and differential, but no play in the rear wheels themselves. The peculiar part of it is that when the car is jerking, the motor is firing perfectly.

Warren, O. P. D. TAYLOR.

—Excess play in the universals would be enough to cause the jerking, but assuming that this is not the cause you may look to the clutch, which may be gripping only at intervals. Do not throttle the motor down too low and expect it to pull smoothly. The usual cause of such action is play somewhere between the rear axle and the motor and if you will remove this play the jerking no doubt will vanish. It would be wise to take the car to the nearest Buick agent and have him look it over.

Crank With Throttle Nearly Closed

Editor THE AUTOMOBILE:—What, in your opinion, is the best way to crank a motor, with the throttle open or nearly closed?

Albany, N. Y. E. A. STOKES.

—It is preferable to crank the motor with the throttle only opened a small amount, say an inch or an inch and a quarter movement on the quadrant. With some carbureters it is impossible to start the motor with the throttle wide open, while with the others it is generally done with difficulty.

Please Sign Your Letters

Communications to the Rostrum should be signed in full and the writer's address also stated. A great many letters are forced into the waste basket because of lack of proper identification.

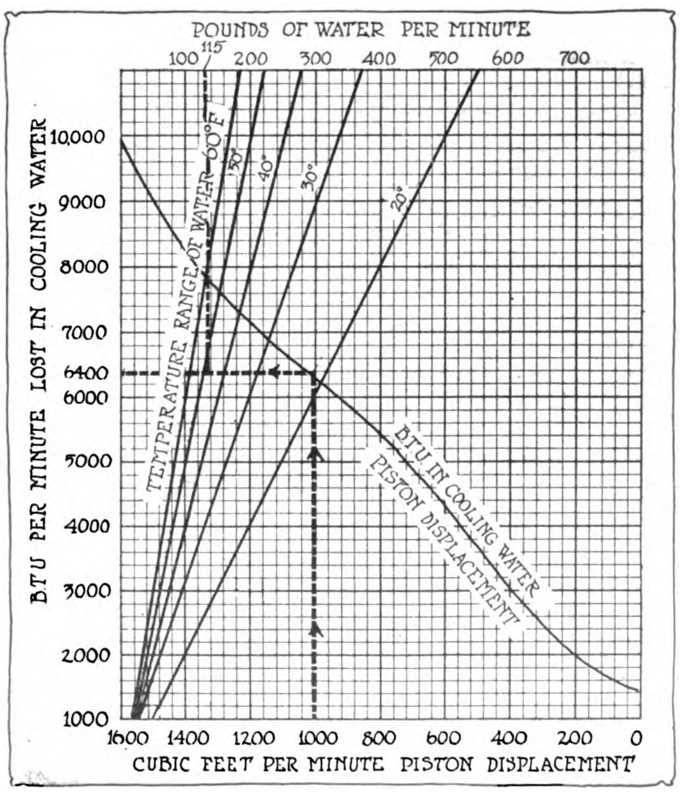

Fig 5—Curve showing pounds of water per minute and B. T. Us. per minute lost in cooling water for a given piston displacement

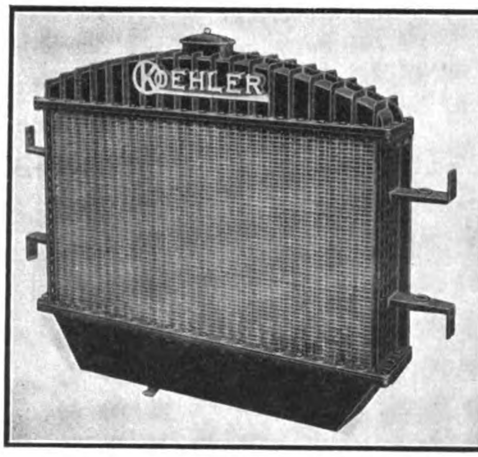

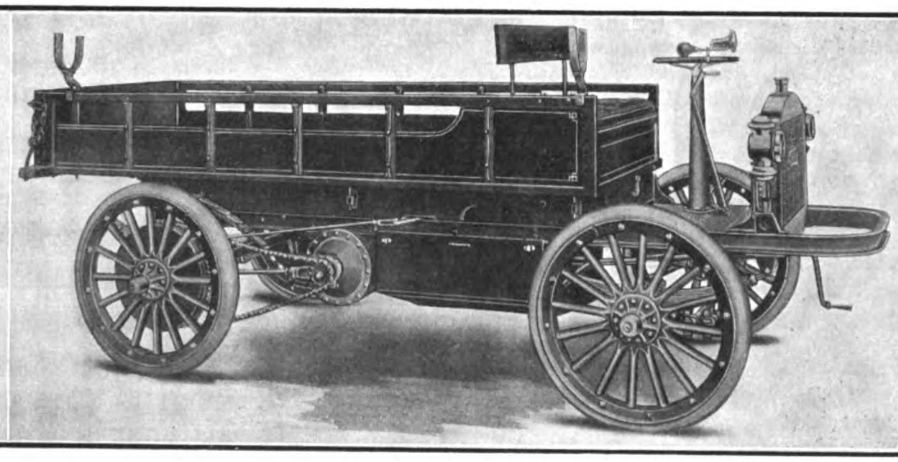

Left—New Koehler radiator with a cooling area of over 1,450 square inches. Right—Koehler 1-ton truck with open type of body

Koehler Has Improved Radiator and Gearset

Two-Speed Planetary System Housed with Jackshaft—Under-Body Included in Chassis Price of $725

ONE of the important low-priced commercial car announcements for 1915 comes from the H. J. Koehler S. G. Co., New York, which markets a 1-ton chassis selling at $725, including the under-body. The new Koehler, although in essentials the same as the previous model, has been improved where necessary and the most important parts to receive attention are the radiator and gearset.

The new radiator, which is hung between springs, has a cooling area of over 1,450 square inches, it is claimed, and is built up of five separate units. These are the upper head, lower head, the core and two side pieces, to which the lamp brackets are attached. Ninety-nine tubes are used in the present construction and the entire radiator improved upon so as to make it better able to withstand severe strains. An important feature of the Koehler radiator is the ease with which it may be removed and replaced. In the event a part be broken only that part need be replaced.

Gearset Part of Jackshaft Unit

A novel feature of Koehler construction is the two-speed planetary gearset which is contained in a cylindrical housing containing the jackshaft, as shown in the illustration herewith. The jackshaft itself is of one piece from the left-hand sprocket to the differential, which is at the end of the planetary set and may be seen in the illustration. The jackshaft transmission and differential run in oil and thus the wear is reduced considerably, while an added feature is the ease with which the planetary set in this unit may be removed for inspection purposes.

By taking off the end of the housing nearest the set the entire unit may be slipped out of the housing. The high-speed clutch of the set has a metal-to-metal contact and the low and reverse speeds are individual bands lined with wire-woven asbestos. It is stated that the operating speed of this gearset is one-half that of the ordinary construction, thus making for long life of the parts. The driving pinion shown has thirteen teeth and the large driven gear has twenty-five. All gears are fully protected from dust.

A two-cylinder motor is installed under the body of the Koehler, the dimensions of this engine being 5.25 by 4 inches. The carbureter used is a Schebler and the magneto a Bosch with fixed spark. As before stated, it drives a planetary set incorporated in the jackshaft and the power then is transmitted by chain to the rear wheels. These are equipped with 36 by 2 1-2-inch solid, demountable tires. The wheelbase is 90 inches.

Sediment Strainer Added

Another slight change in Koehler construction has been the addition of a sediment strainer beneath the gasoline tank and the installation of a combination outlet valve which allows a 2-gallon emergency supply feature.

The express-type car forms the largest part of Koehler production, while a number of types have been brought out which are particularly adapted to some special business.

Technical Service of A. C. A. To Be Broadened

NEW YORK CITY, Aug. 15—It has been decided to place the efficiency bureau of the Automobile Club of America under the direction of the technical committee and to extend its activities.

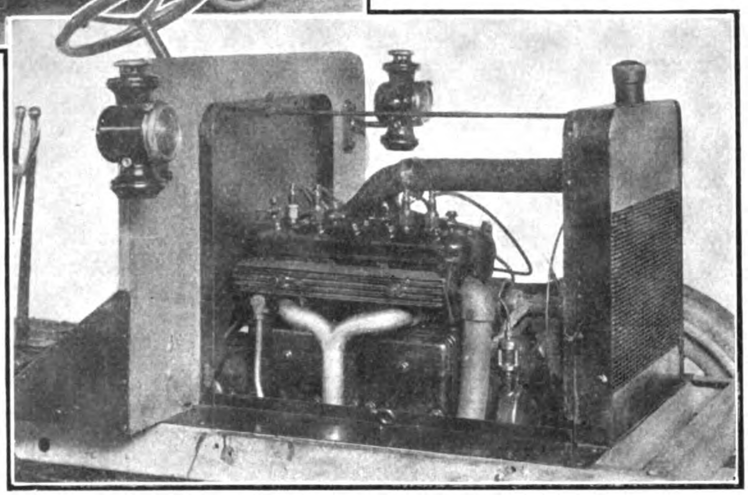
It is the idea to make frequent, perhaps weekly, examinations of members' cars registered in the bureau, a monthly report with recommendations to be sent to the owners. Any repair or adjustment that is urgent will be the subject of an immediate notification to members.

By proving wasteful operation to members and that unsatisfactory delays and discomforts are due to neglect of cars, the bureau hopes to increase the general efficiency of the automobile.

Six-passenger wagonette, $695

$635 Vim Delivery Has Standard Parts

Four Types of Bodies— Unit Power Plant Design— Block Motor of 20 Horsepower



View of motor showing disposition of piping

SIX hundred and thirty-five dollars is the astonishingly low price of the Vim light delivery wagon manufactured by the Touraine Co., Philadelphia, Pa. Yet the car is manufactured of standard parts throughout. It has a four-cylinder Northaway truck motor rated at 20 horsepower, a clutch and gearset in unit with the motor, made by the same concern, these members being capable of transmitting 35 horsepower, and a Weston-Mott rear axle designed for 30 horsepower.

Three other types of bodies mounted on the same chassis are offered, these being the large delivery body for $685, the flare body for $695 and the Wagonette, a 6-passenger bus, for $695. Thus it is seen that a large factor of safety is allowed.

The chassis, with any type of body, has a capacity of 800 pounds, weighs but 1,850, and may be turned in a 36-foot circle, which is made possible by the 89-inch wheelbase. The loading space is 56 inches long and 42 inches wide, only 10 inches overhanging the rear. The floor is low, only 24 inches from the ground, being carried directly by the frame members. The motor is an L-head block construction with integral exhaust manifold and separate Y intake. The bore is 3 inches and the stroke 4.5 inches, giving an S. A. E. rating of 14.4. The valves are inclosed by two removable coverplates. The crankshaft bearings are 2 inches in diameter and three main bearings are employed. Cooling is maintained by a honeycomb radiator, the circulation of the water being on the thermo-syphon principle and assisted by a belt-driven fan. Lubrication is effected by a combination force-feed and splash system with a capacity of 2 gallons, sufficient for 600 miles. Ignition is supplied by an Atwater Kent system.

The clutch is a leather-faced cone type 12 inches in diameter and with a 2.5-inch face. The gearset is a selective sliding design, with gears of 3-4-inch face. The shafts are all of chrome nickel alloy, on imported annular bearings.

The front axle is a special drop-forged, I-beam section, the knuckles and steering arms being drop-forged and heat-treated. The rear axle, as already stated, is a Weston-Mott construction and is equipped with a Brown-Lipe differential. The drive shafts are 1 1-8 inches in diameter. The universals are of Hartford make.

Two sets of brakes, both acting on the rear wheels, are used, the contracting brakes for service and the expanding for emergency use. The drums are 10 inches in diameter and 2.5 inches wide.

Left drive with right control is employed. The maximum speed is 30 miles per hour. The tires are 30 by 3 inches, although 31 by 3.5-inch tires are optional at an increase of $20.

Vim chassis with flare body

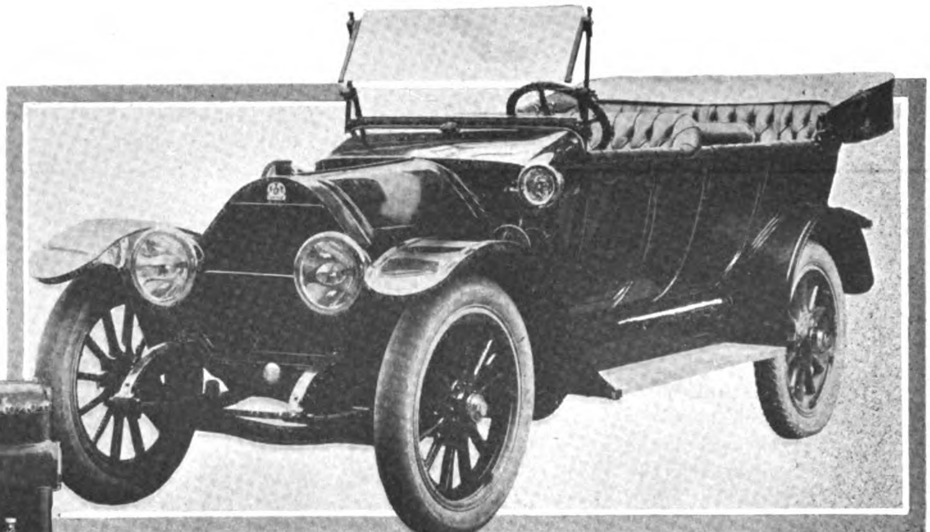
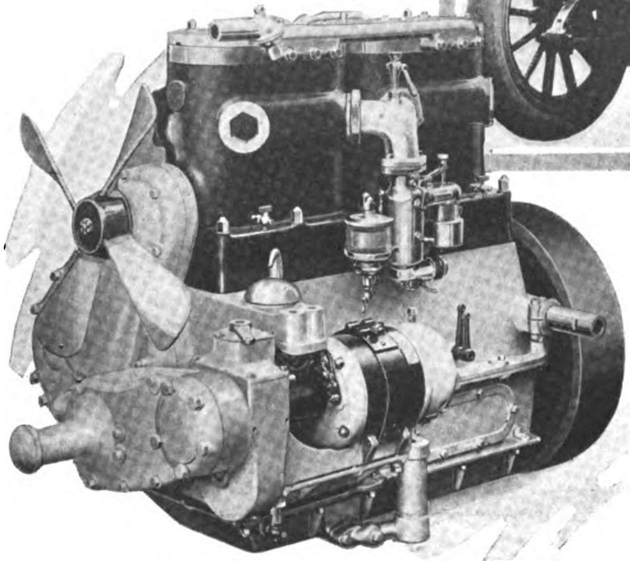
Lyons-Knight Has Streamline Body

Few Mechanical Changes of Importance —All Instruments Now On Cowl Board



Lyons-Knight touring car of foreign lines



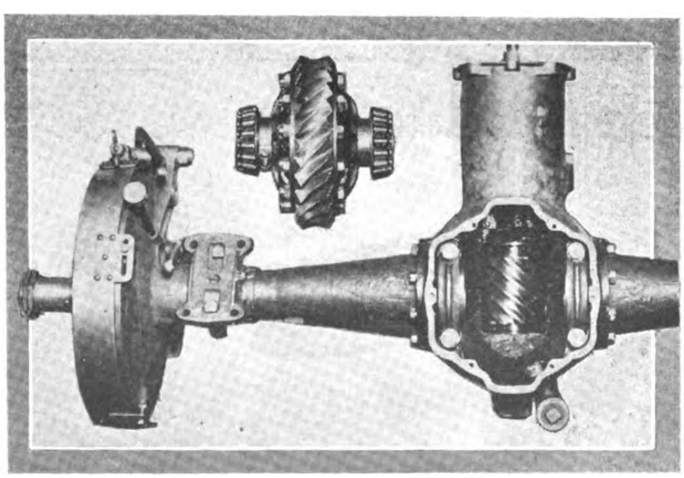
Side view of motor used in Lyons-Knight cars

MAINTAINING the same prices and practically the same chassis as last year, the model K Lyons-Knight for 1915 is marked by many innovations in body construction. For the coming seasons the Lyons-Atlas Co., Indianapolis, Ind., offers a choice of four bodies on a single chassis model. The prices are, for the seven-passenger touring car, $2,980; the five-passenger, $2,900; five-passenger sedan, $3,900, and seven-passenger limousine, $4,300. In addition to this body line the purchaser has a choice of two-passenger roadsters which will be built to special order.

The Lyons-Knight chassis upon which these bodies are mounted has a Knight power plant and a worm drive rear axle. The chassis has a wheelbase of 130 inches and is equipped with 37 by 5-inch tires, the rear ones with non-skid tread. All these features distinguish the previous line of Lyons-Knight cars and it is only in the development of the streamline design that the most radical changes are apparent. The upholstery is now carried along the tops of the doors, giving a straight-line effect from front to rear, and the sides are now higher with wider front and rear seats. The rear seat is unusually wide, measuring 52 inches from side to side.

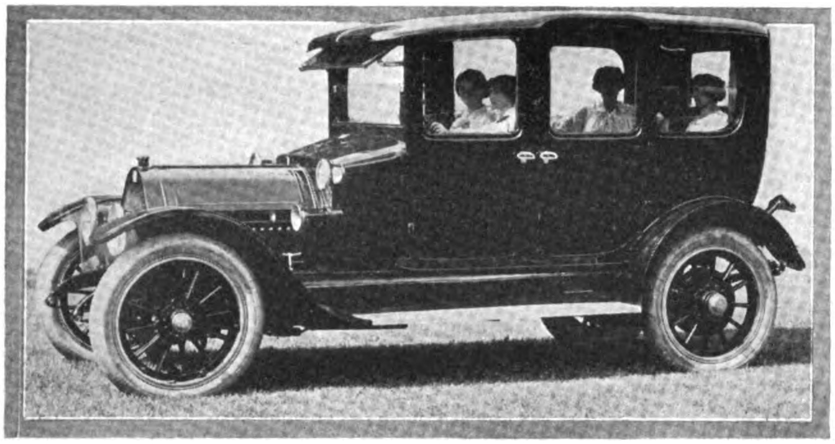
Instruments on Dash

All instruments such as speedometer, clock, gasoline gauge, oil pressure gauge, ignition and lighting switch and so on now are mounted flush with the instrument board. A convenient feature of the lighting control is a switch which may be locked in any combination of lights. Equipment is somewhat more complete than formerly and consists of a Golde one-man top, option of Jiffy or Collins curtains, Warner speedometer, a combination double tire holder and trunk rack, two extra demountable rims and a Manzel power tire-pump. Mechanically, there is no change in the car. The Knight engine, which is manufactured by the Lyons-Atlas company, is a four-cylinder, 4 1-2 by 5 1-2, and, although the S. A. E. rating is but 33 4, factory test has shown that it develops 52 horsepower at 1,200 r.p.m., and a maximum of 76 at 2,000. The cylinders are cast in pairs and the crankcase, chaincase and cylinder head covers are cast of aluminum. The feature of covering the cylinder heads to keep out dirt and moisture and to protect the spark plugs is exclusive with the Lyons-Knight engine. Hard-rubber buttons are mounted on the covers by which the spark plugs can be short-circuited and tested without removing the covers. Crank and eccentric shafts are carried on five bearings and fitted with adjustable bronze bushings, babbitt lined. These two shafts, as well as the connecting-rods, are heat-treated chrome-nickel steel. The eccentric shaft together with magneto pump, starter and fan are driven by silent chain in order to do away with possibility of noise from the timing drive, a feature most necessary with the sleeve valve type of engine on account of



Worm drive rear axle continued this season the quietness of the valve operation.

Lubrication is by force feed to all bearings, pistons and sleeve. An oil reservoir is located in a sub-base of the crankcase, having an intermediate air space to prevent overheating of the oil. A plunger pump operated by one of the sleeve eccentric rods takes the oil from the reservoir and forces it under pressure to the crankshaft and eccentric shaft bearings, the eccentric rod bearing and thence through holes drilled through the center of the crankshaft to the connecting-rods. The latter are hollow and the oil is forced through their interior to the upper bearing. The piston pins likewise are hollow, and the oil flows to these to the outside of the piston, thence through holes in the sleeves to the cylinder walls, so that all friction surfaces are lubricated by a positive flow. An adjustable oil pressure regulator is connected with the throttle lever so that the pressure of the oil is in proportion to the engine speed.



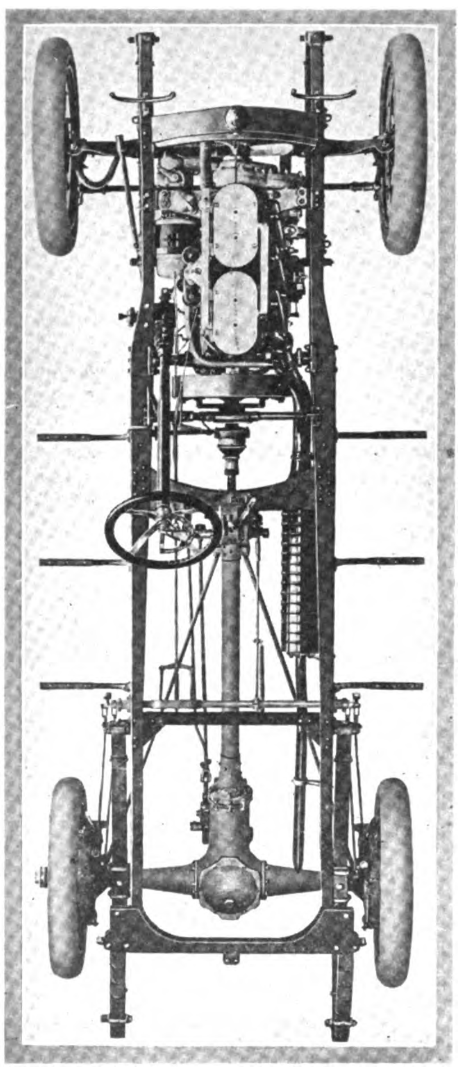
Inclosed sedan body on Lyons chassis

Ignition is furnished by a Simms dual, high-tension magneto of the water-proof type. Cooling is by a centrifugal pump, honeycomb radiator and a four-blade cast aluminum fan, which is operated by a silent type of chain. Following the European custom, the fuel tank is mounted in the dash cowl, giving a gravity feed to the specially designed Stromberg carbureter.

Single Electrical Unit

Cranking and lighting is provided by a single unit Northeast system which is connected directly to the front end of the crankshaft to a silent chain. A simple foot button connects the starter, and when released converts the motor into a generator for charging the storage battery, the latter furnishing current for the starter, the lighting equipment and the electric horn.

From the motor power is transmitted through a three-plate dry disk clutch, three-speed selective gearset, worm final reduction and floating axle. The clutch is inclosed in the flywheel, the single central floating member engaging by being gradually compressed between the two outside plates through the action of three powerful toggle joints. A special bronze casting is used for housing the gearset differential and worm gear, which are in unit and to which is attached the seamless steel tubing on which the wheels are mounted. Differential case and wheels are fitted with Timken bearings. The 3-inch torsion tube incloses the driveshaft and terminates in a large, hollow, bronze, ball and socket joint at the forward end and is attached to the heavy center cross-member of the frame.



Plan view of the chassis on which all body types are mounted

One of the main features of the Lyons-Knight design is the worm drive. This is of the underslung type and runs in oil. In spite of the fact that the worm is underneath, it has a clearance of 10 inches above the road.

Suspension is by three-quarter elliptic springs at the rear, 54 by 2 1-2 inches in size, and one-half elliptic springs in the front, 38 by 2 1-2 inches, all ends being provided with bronze additions to give easy replacement in case of wear. The front springs are very quiet, being arranged so that they hold the front axle parallel with the rear axle, and prevent wabbling of the front wheels on rough roads. All models are equipped regularly with wood wheels which carry demountable rims, accommodating either straight-side or clincher tires. Expanding and contracting brakes act on 16 by 2 1-2 drums. Wire wheels may be obtained at an additional cost, not being specified.

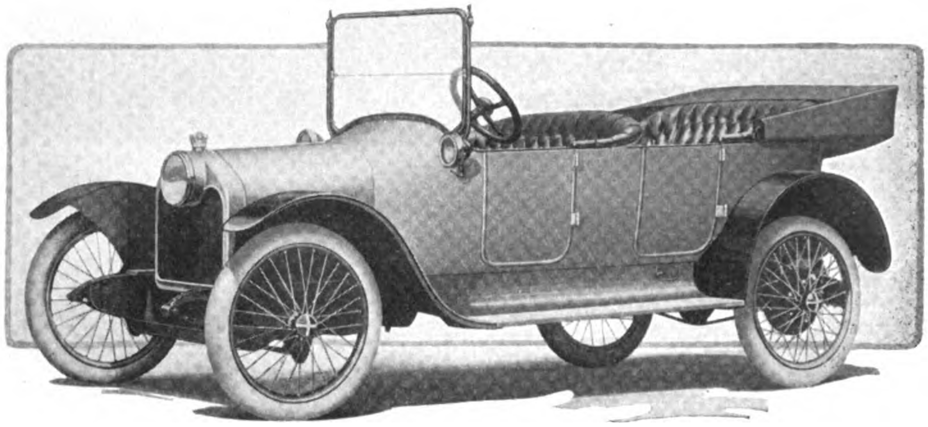
Easy riding qualities are made a particular point in this car, the design being made with an eye to equal distribution of the weight and correct spring suspension.

Norway's Duty 12 Per Cent.

CHRISTIANIA, NORWAY, Aug. 10—Automobiles shipped to Norway completely set up or assembled are subject to an import duty of 12 per cent. ad valorem; if shipped separately, bodies to a duty of 15 per cent.; motors to a duty of 10 per cent. ad valorem; automobile wheels pay $0.61 per 100 pounds; other parts, such as steel are dutiable $1.82 per 100 pounds; brass or copper, $6.08 per 100 pounds; nickel parts, $12.15 per 100 pounds; varnished or tinned iron, $3.64 per 100 pounds.

Accessories are assessed according to the material of which they are made at the above rate for parts; speedometers are subject to a duty of 10 per cent. ad valorem. Rubber tires are subject to a duty of $3.64 per 100 pounds. Lamps, bells, horns are assessed $6.08 per 100 pounds. Motorcycles are classed as bicycles and are assessed $8.04; in addition, the motor, classified as machinery is assessed 10 per cent. ad valorem; parts of motorcycles, apart from the motor, tires and accessories, are classified as parts of bicycles at $30.39 per 100 pounds; parts of the motor classified as machinery are subject to 10 per cent. ad valorem; the invoice must show the value of the motor, whether part of a motorcycle, or otherwise; tires are assessed $3.64 per 100 pounds.

Briscoe Adds Roadster and Coupé



Five-passenger Briscoe touring car for 1915. Note center headlight.

Few Mechanical Changes—High-Speed Motor—Combined Intake and Exhaust Manifold—Streamline Bodies

BRISCOE cars, which are now issuing from the Jackson, Mich., plants of the Briscoe Motor Co. to the tune of about ten a day, are proof of the fact that a high-grade light car of European design can be efficiently manufactured in this country.

Benjamin Briscoe, old-timer in the industry and head of the company bearing his name, did the experimental work and designing of the car in France and exhibited the result of his labors to the American public for the first time at the last automobile shows. The distinctive design and pleasing appearance of the car took the American fancy at once, and with this as a starter the concern has since perfected a far-reaching selling organization.

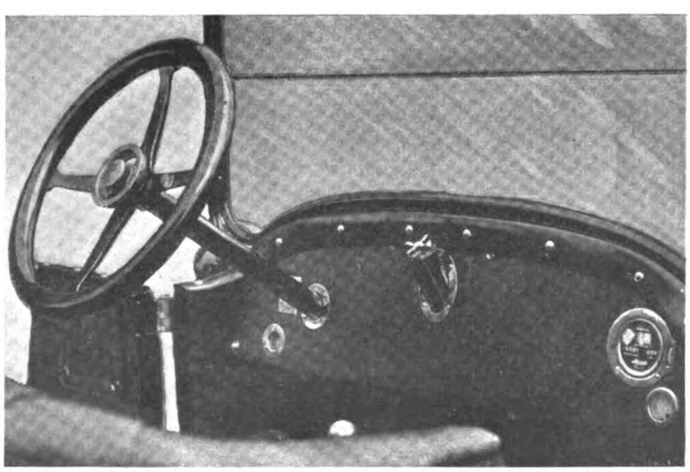
Changes for Production Demands

Though essentially the same as the experimental models which came over from Europe, the car has been put through its paces at the Jackson factories as well as on foreign soil, and the cars now coming through show some minor differences to meet manufacturing conditions and production demands without in any way detracting from mechanical excellence or appearance.

Outwardly, the single headlight in the center of the top of the radiator shell is perhaps the most distinctive feature, while the streamline body and unbroken curves are in accord with the very latest in the body-making art. French gray with black upholstering have been decided upon for the standard colors, and this combination is very pleasing.

Roadster and Coupé Added

Besides the five-passenger touring car models which were the only types seen at the national shows, the line has been extended to take in a roadster and a coupé, both mounted on the standard chassis. The former is styled the Clover Leaf runabout because the seats are so arranged as to give the appearance of a clover leaf. That is, three may be accommodated, the two outside seats being in line, while the middle seat is somewhat back of them.



Cowl board and control of new Briscoe. Note unique spark and throttle lever control on wheel

Body lines of both the roadster and the coupé are very pleasing. The rear is really of torpedo shape and somewhat similar to the back end of several well-known racing cars, notably the Peugeot. The coupé top is very rakish and low in appearance, though of standard height. Windows are large and are designed to afford the driver views of the road from all angles.

As at first planned, the price of the Briscoe, with electric horn, lamps, accumulator battery, tools, jack and so on, is $750, and when equipped with electric starter and generator, top and boot, windshield and speedometer in addition the figure is $900.

Car Weighs Only 1,700 Pounds

The Briscoe is truly a light car, for its weight is 1,700 pounds, despite the fact that the wheelbase is amply long—107 inches. Tread is standard at 56 inches and wheels are of wire, on which are mounted 30 by 3 1-2-inch tires all around.

In accordance with present-day practice, the gasoline tank, of 9 gallons capacity, is mounted in the cowl dash, affording direct gravity feed to the carbureter.

The motor is of the high-speed type, with the cylinders block cast and of L-head form. Bore and stroke are 3 1-8 by 5 1-8 inches respectively, according the engine an S. A. E. horsepower rating of 15.6 and a stroke bore ratio of 1.64. Due to this ratio, the horsepower developed is greatly in excess of that given the motor by the formula.

The valves are all located on the right and covered in accordance with regular practice by readily removable plates. One feature of this motor which is of note is the covering of the valve pockets by a valve plate which is securely bolted to the main cylinder casting. This single plate makes it easy to expose valves and explosion chambers and facilitates the removal of carbon, not only from these parts but from the piston heads as well.

The moving parts are all substantially made and well balanced. There are two main crankshaft bearings, while the camshaft is also carried on two. Connecting-rods have two-bolt strap ends and are steel forgings of chrome vanadium composition, properly heat treated. The pistons, each of which carries two diagonally split rings, are cast from special piston metal, which is said to be very light in weight, thus permitting of higher piston speeds without vibration.

Silent Chain Drive for Camshaft

The drive for the camshaft, as well as for the magneto, is of uncommon form in that a silent chain, located at the rear of the cylinder block instead of in the usual forward position, takes care of these parts. There is a single chain which is driven by the crankshaft just back of the rear main bearing, passes over the camshaft sprocket and on to the magneto drive sprocket above. This drive is entirely housed against oil leakage and is located between the cylinder block and the flywheel.

Magneto Protrudes Through Floorboards

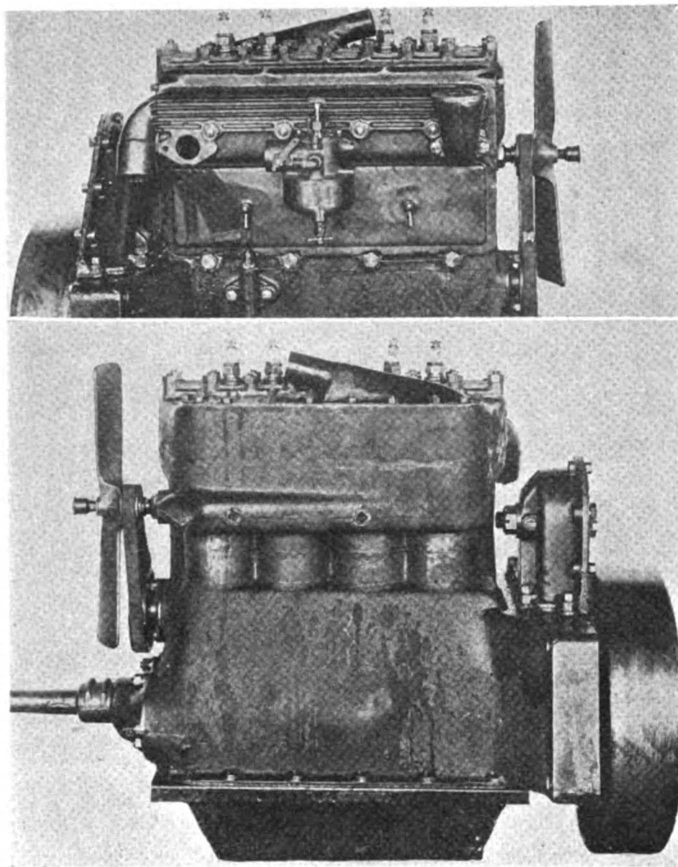
Due to this drive mechanism, the magneto, which is a Splitdorf, Model EU4, is mounted on a bracket attached to the gearcase housing, and in this position naturally protrudes through the inclined floor boards of the front compartment of the car. A metal plate goes over that portion of the magneto which comes through and this may readily be removed for access to the ignition unit. Locating the magneto in this position is not known to American car practice, but it is a departure from usual design.

The lower part of the crankcase may be removed and permits of the inspection or adjustment of the connecting-rod, crankshaft and camshaft bearings. The upper part is in unit with the cylinder block casting, and thus the barrel form of crankcase construction, which is common to American practice, is attained. This design makes a very rigid construction and is another enemy to appreciable vibration.

Combined Intake and Exhaust Manifold

The construction of the combined intake and exhaust manifold, which is placed above the valve cover, is very neat. Being cast together, compactness is attained, and lightness as well. The intake passages are above those distributing the gases internally to the intake ports. The combination also serves to heat the incoming gases, due to their proximity to the exhaust and better vaporization is the result.

Due to this manifold arrangement, the carbureter flange bolts directly to the opening at the center of the intake portion of the combination and there is the least possible amount of exposed piping. Of course, this rather high mounting of the carbureter on the motor is made possible through the fact that the gasoline tank is considerably above it in the cowl. The carbureter used is a Holley.



Upper—Valve side of Briscoe motor, showing combined exhaust and intake manifolds
Lower—Left side of motor showing simplicity of casting

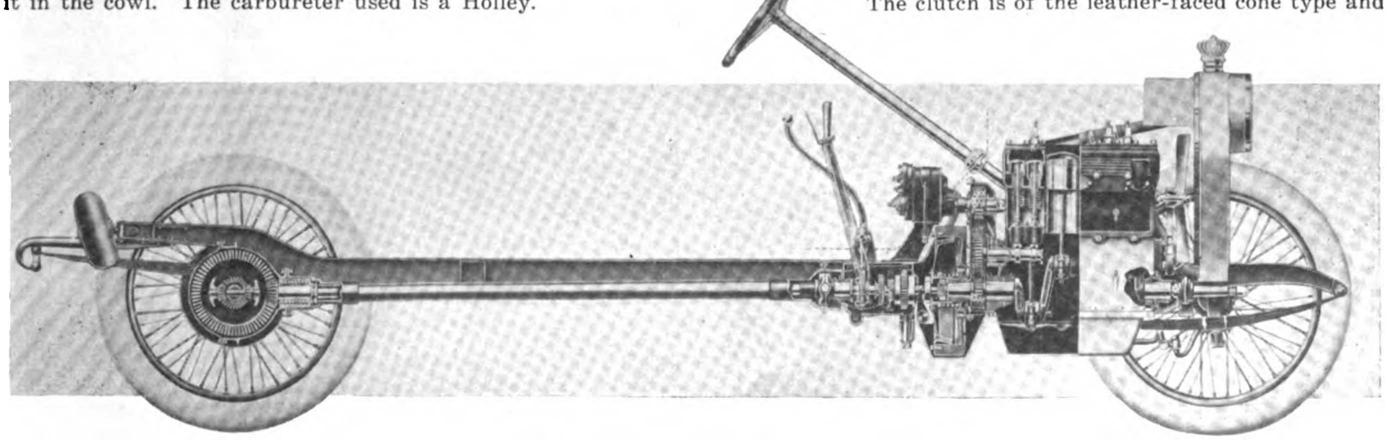
Lubrication is provided for by the conventional form of constant level splash system, there being a separate trough under each connecting-rod to take care of the splash function, while a pump on the right side of the crankcase and operated by the camshaft keeps the troughs at the proper level. The lower part of the crankcase is the reservoir, and the flow is checked by the dash sight feed.

Thermo-Syphon Cooling

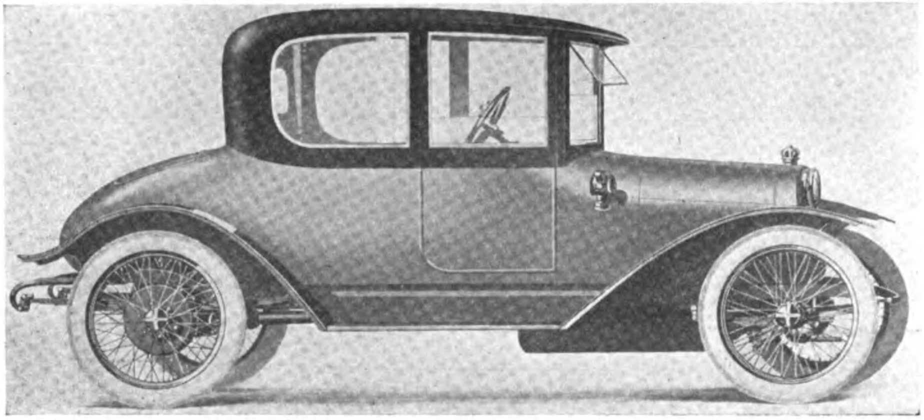
Cooling is by thermo-syphon and inlet and outlet connections are of large diameter to afford a free flow.

Although the flywheel is not inclosed, a substantial yoke passes around it on either side and these arms carry the gearbox. Thus the latter is virtually in unit with the motor, and a three-point suspended unit power plant construction is attained.

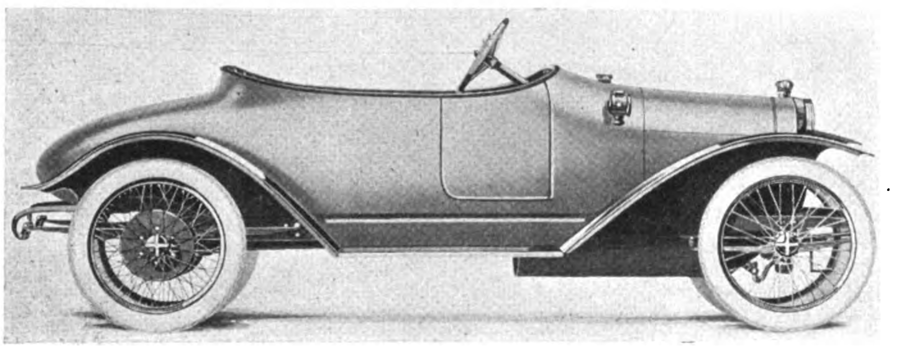
The clutch is of the leather-faced cone type and



Part sectional view of Briscoe chassis on which are mounted touring, roadster, or coupé bodies. Note mounting of magneto on bracket above gearcase and protruding through front floorboards as shown by dotted lines



New Briscoe coupé. Note streamline front and torpedo-type rear as well as general low appearance



Briscoe torpedo three-passenger roadster, called the Clover Leaf because of the seating arrangement

acts within the flywheel rim. Back of it is a three-speed gearset of compact design. This is of selective type and has center control. The gears and shafts are made of chrome vanadium steel.

Combined Starter and Generator

To the right of the gearbox and bolting to the right arm of the yoke passing around the flywheel is placed the Aplco combined electric cranking motor and generator. This unit connects through a completely inclosed silent chain to the main driveshaft between the clutch and the gears in the gearbox. The ratio between this electric unit and the shaft is 2 1-2 to 1. As is usual with combination motor-generator units, the device draws on the storage battery for starting purposes, and, when the engine runs under its own power, becomes a generator for sending current back to the battery.

An automatic cutout switch takes care of the battery charging and cuts the generator into the charging circuit at 14 miles an hour. As a motor the device will turn the crankshaft at the rate of about 150 revolutions a minute, and is unusually silent while doing it. The Aplco unit is of the 12-volt type and the battery, which is placed under the rear floorboards, is rated at 12 volts and 35 amperes. Fourteen-volt side and tail lamps of 2 candlepower are fitted, while the single headlight is a 7-volt, 18-candlepower one.

Driveshaft Is Inclosed

The drive from the gearbox to the rear is through a torsion-tube-inclosed shaft equipped with a universal joint, also inclosed at the forward end. The tube takes the drive and the torque in the usual way, and the power goes direct to the bevel gears of the rear axle which is of the floating type with live axles accepting only the drive. The weight of the car is carried on 4-inch Hyatt roller bearings and there is also a ball thrust bearing independent of the live axles. Although the standard drive ratio is 3 3-4 to 1, the purchaser may have a 4 to 1 ratio, if he desires. The axle gears are also carried on Hyatts.

There are two internal expanding brake drums and shoes on each rear wheel, one operating from emergency and the other from the service brake control. Steering is on the left and mechanism is of the worm and gear type, mounted upon a trunnion and forged from vanadium steel. Rather unusual spark and throttle controls are used on the steering wheel. These are not used with a lever and quadrant construction, but simply rotate on the steering post center. The spark control is a button which may be turned, while a large ring outside of it turns to control the throttle.

The suspension of the Briscoe chassis is by means of semi-elliptic springs all around. In the rear, spring horns attach to the frame and take the rear ends of the long springs. Easy riding is claimed, due to the length of these members.

The frame, which kicks up at the rear to clear the axle, is made of special frame steel having a channel section 3 3-4 inches high and 1 1-2 inch wide and made of 5-32-inch metal.

Some of the principal motor dimensions are given:

Valve diameter—1 3-4 inch.

Crankshaft bearings—Front, 1 7-8-inch diameter by 3 inches length; rear, 1 7-8-inch diameter by 3 1-8 inches length.

Connecting-rod bearings—1 7-8-inch diameter by 1 3-4 inch length.

Connecting-rod length—10 1-4 inches center to center.

NEW YORK CITY, Aug. 21—The Bosch Magneto Co., this city. reports that the European war will not hamper it in getting out its product. It states that the raw material which it has been getting heretofore from Europe it is now getting from domestic markets.

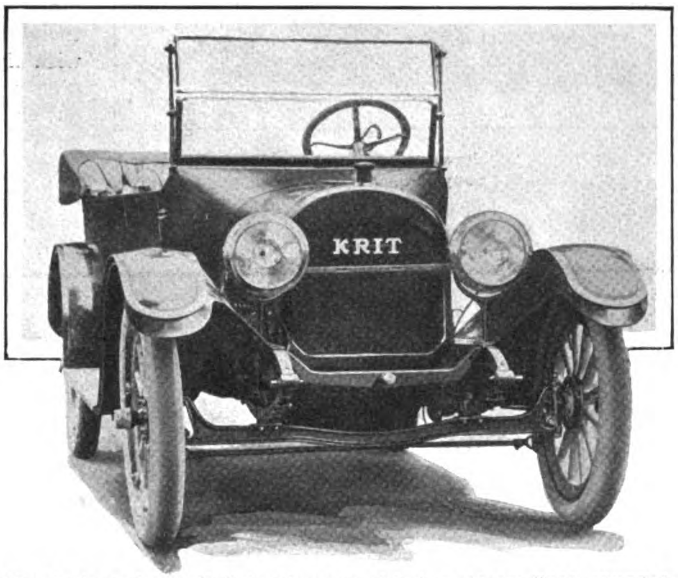
Krit Adds Cabriolet—Lowers Prices

Touring Cars and Roadsters $55 Less—Motor 25 Per Cent. More Powerful—Bodies More Roomy—Center Control

ALTHOUGH the price of the 1915 Krit models has been materially reduced, still greater refinement has been accorded them. Continuing the same general attractive outward appearance as in 1914, they have larger and more roomy bodies, a more powerful motor, better and most complete equipment and a number of detail chassis alterations leading to greater efficiency.



Front view of 1915 Krit touring car, showing stream lines, rounded-over radiator and crowned fenders

The price on the roadster and touring car models has been reduced from $1,050 to $995 with full electric equipment for cranking and lighting, one-man top, non-skid rear tires and additional instrument board units. Besides these two body styles, the Krit company has added a cabriolet type to meet a growing demand for such an all-weather machine. This is to sell for $1,295. The special touring car and roadster which were well received last season have their successors in the 1915 line also. In either roadster or touring car form, the special sells for $1,070 with five wire wheels, leather-faced seat covers and optional color in addition to the equipment with which the regular models are fitted.

Fenders Are Crowned

While the body lines are substantially the same as they were, a trifle has been added to the width, while the touring car has been increased 4 inches in length to give more room, most of which has been accorded the front seat. Another distinctive touch which adds to the effect of the streamlines is the crowning of the fenders, a touch which nearly all makers are now recognizing as meritorious. Rounded top radiator with coped over edges and sloping hood which conforms to it have been unchanged.

One new body feature is the doing away with all mouldings along the top edges. Instead, the metal of the sides rounds over the top edges and lends a very smooth and clean look to the car. Door tops conform to the same idea. This construction makes a better manufacturing proposition and at the same time is advantageous both from the standpoint of appearance and serviceability.

In the motor, while the basic design is retained, a new oiling system has been incorporated which combines the flywheel pump system which was heretofore used along with a pump circulation. It is a combination of force feed and splash. In the new arrangement, the reservoir which forms the lower portion of the crankcase is open on top with the exception of four troughs, one beneath each connecting-rod. The oil is positively forced from the reservoir to each of these troughs by a gear pump attached to the front end of the magneto time gear shaft. The rods dipping in the troughs cause a splash, lubricating all parts of the motor, and, as each trough is supplied independently by a lead from the main oil manifold running along the inside of the crankcase, the lubrication of each cylinder is assured, whether running on the level or on any kind of grade. The flywheel system which was heretofore used alone, now is the secondary supply, so that lubrication is very effective.

North East Electrical Unit

An important change has been made in the electric equipment, a North East single unit system replacing that fitted last year. This new motor-generator is 38 pounds lighter than the corresponding unit heretofore used. It is mounted on the left forward side of the motor on a bracket integral with the crankcase. This unit connects to the crankshaft through a shaft running back to a sprocket which in turn connects with another sprocket on the crankshaft and between its rear end bearing and the flywheel. The whole chain mechanism is completely housed within an integral ex-

steer is practically standard with the majority of American cars now. Another improvement is in the center cross member of the frame which this year houses the brake cross rods and levers, relieving them of twisting strains and cleaning up the chassis.

The Krit motor, which is of the block cast type with L-head cylinders, has a bore of 3 3-4 inches and a stroke of 4 inches, giving it an S. A. E. formula rating of 22.5 horsepower, although due to the high speed design with light reciprocating parts, the engine will develop close to 30 horsepower on the block. Its maximum power output is attained at a crankshaft speed of about 2,000 revolutions, although it can be run as high as 3,100 revolutions.

tension of the flywheel housing. The shaft running from the electric unit to the upper sprocket is fitted with two leather universal joints. The ratio between the motor-generator and the crankshaft is 2.96 to 1.

The unit operates in the usual way. When used for cranking purposes, a switch sends current from the storage battery to the unit, it being temporarily transformed into an electric motor. After the engine is running, then the unit becomes a generator and sends current back to the battery. The latter is a 120 ampere-hour Willard and is located to the right of the gearbox inside the frame and under the front floor boards. The new cranking system is very silent and turns the engine at 175 revolutions a minute. On test, it rotated the shaft for 51 minutes with a fully charged battery. The system is a 12-volt, two-wire type.

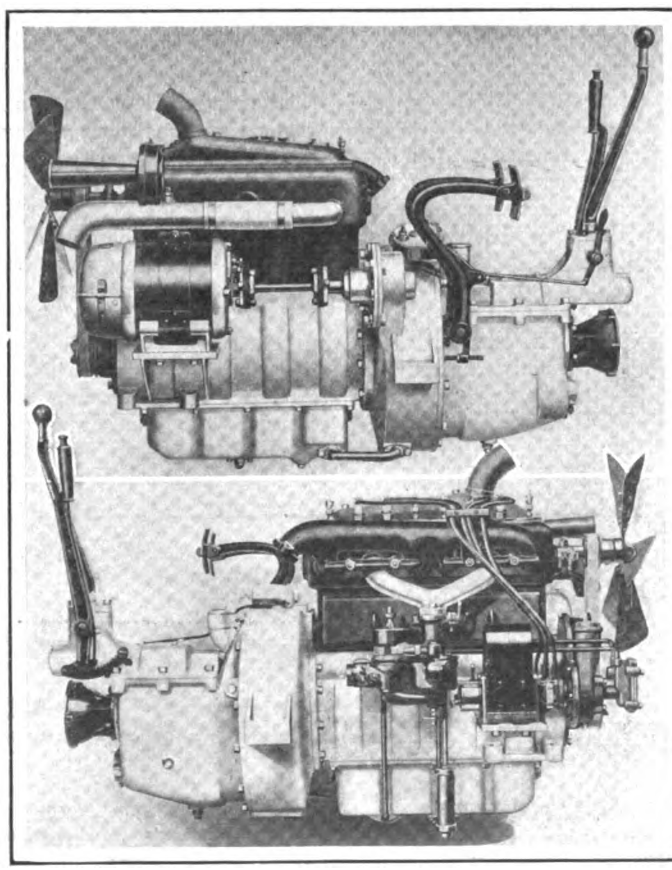
25 Per Cent. More Power

Some 25 per cent. has been added to the power of the motor, through the increasing of the valve size from 1 1-4 inch to 1 3-8 inch diameter; through the light weight pistons, each of which carries three concentric rings, and through the redesigning of the camshaft to allow for wider valve opening and closer tappet adjustment.

Center Control Adopted

Three chassis changes are of special note. First of these is the shifting to center control from the former left position of the levers—the Krit company has always advocated left drive since its inception in 1909. Second is the adoption of fore and aft steering mechanism to replace the cross type. This relieves the frame of the steering side thrust and therefore makes steering easier. The fore and aft

In general construction, the motor is entirely conventional. The unit power plant idea is carried out by bolting the gearbox directly to the flywheel housing, supporting the unit at either side of this housing, and cradling the front end on a frame cross member at its center. Valves, magneto and carbureter are on the right, and the exhaust manifold, with a separate opening to each cylinder, runs above the two branch intake, which has a common opening for each two cylinders. Due to a new design of Stromberg carbureter fitted this year, the shortening somewhat of the intake manifold has been made possible with better carburetion the theoretical result. The magneto is of the Bosch high-tension type.



Upper—Left side of Krit unit power plant, showing mounting of North East electrical unit for lighting and starting on bracket at the side of the crankcase. Note center control levers on gearbox and horn mounted on motor.

Lower—Right side of power plant showing intake and exhaust manifolds, new Stromberg carbureter and Bosch high-tension magneto

One distinctive feature of the Krit motor is the mounting of the crankshaft on two annular ball bearings of S. R. O. make. This design has proven very satisfactory, it is said.

Aluminum Cuts Weight

Due to the great amount of aluminum used with the motor, the Krit engineers believe they have reduced the power plant weight to the minimum, although strength is increased by the use of this material. The crankcase, gearcase, oil reservoir, water pipes and intake pipe are of cast aluminum, and the total weight of the engine, with magneto and carbureter, is 276 pounds. The complete gearset weighs 73 pounds, and the electric unit 45 pounds, bringing the total weight of the unit power plant to 394 pounds. This lightness is commendable and leads to greater car efficiency.

The drive back from the motor is through a multiple saw steel disk clutch which is within the flywheel. The housing of the latter is connected by a pipe to the oil reservoir so that the clutch runs constantly in a bath of oil. The drive shaft in the gearset is mounted on annular ball bearings and is cut from heat-treated chrome-vanadium steel, the gears, however, being made of chrome-nickel steel, heat-treated and tempered in oil. Their faces are of ample width for their service. The gearbox affords the usual speed changes—three forward and reverse.

Few Changes in Chassis

Except for the few changes in the chassis which have been enumerated, it remains of the same general construction as from the beginning. The drive to the rear axle is through a vanadium steel driveshaft inclosed within a torque tube, and fitted with a Spicer universal joint at its front end. Diagonal radius rods run from the front end of the tube back to the outer ends of the rear axle housing, and they, together with the tube, take the drive and the torque and preserve the proper alignment of the various units.

The rear axle is of the semi-floating type and Hyatt roller bearings are fitted, with a ball thrust bearing on the drive pinion. The brakes are of the usual internal expanding and external contracting type acting upon 10 by 2-inch drums. Rear springs continue to be of the elliptic type, underslung from the axle. Their rear ends are of the scroll form, and this suspension makes for resiliency and consequently for easy riding.

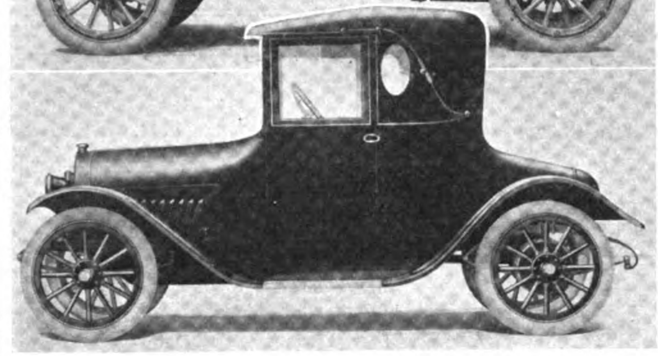
The frame is made from specially heat-treated steel, 5-32 inch in thickness, with a channel depth of 3 5-8 inches. It is of the single-drop type and curves in at the front end in bottle-neck form, thus providing for lower center of gravity and a short turning radius—29 feet 4 inches. There are three frame cross members.

All Instruments Grouped

The gasoline tank under the cowl and hidden by the leather-covered instrument board, through which projects the filled pipe, was a feature of the 1914 Krit and is retained without change for 1915. There is capacity for 10 gallons for direct use. A new feature, however, is the grouping of all the dash instruments on a single plate which is mounted on the instrument board. Containing gasoline gauge, Stewart speedometer, ammeter, switches and carbureter air control, this arrangement makes it easy to illuminate all the devices by the one dash lamp, which is added this year.

Bodies Are More Roomy

Roominess in the bodies is very noticeable, and due to the increasing of the size of the front compartment, it has been possible to lower the front seat—an item for better appearance and greater comfort. Doors have been widened, and ready access from any point is thus augmented. A new design of spare tire carrier is provided which is very rigid.



Upper—New Krit roadster, showing streamline design. Note rear deck and graceful lines of crowned fenders

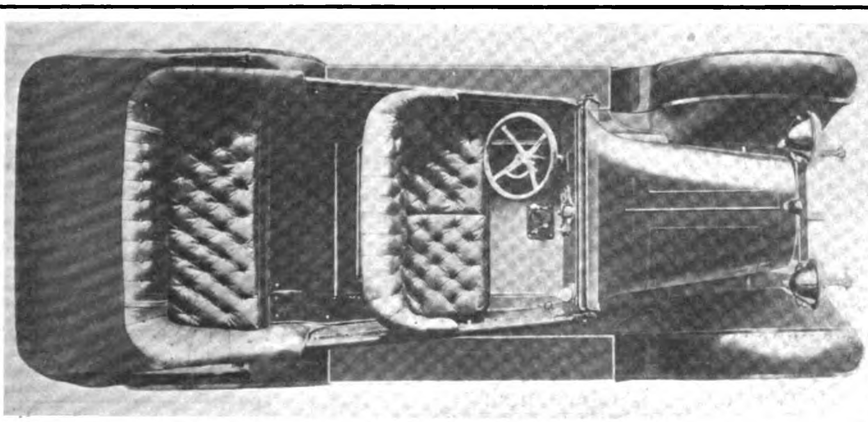
Lower—New Krit cabriolet which is added to the line for 1915. It is designed to meet the growing demand for an all-weather vehicle. It sells for $1,295

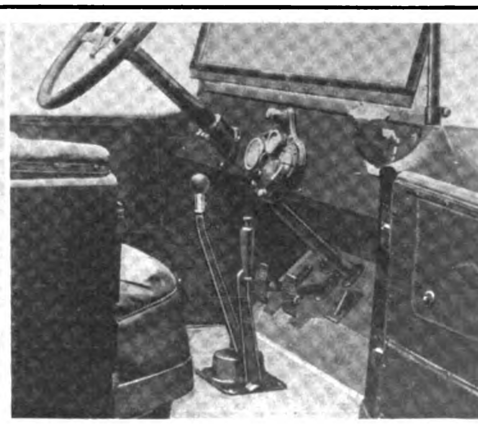
National Automobiling School Created in Honduras

NEW YORK CITY, Aug. 22—On July 4, 1914, the president of Honduras issued an executive order creating a school of instruction for automobilists, to be known as Escuela Nacional de Automovilistas, with the object to teach, theoretically and practically, the construction, working and handling of automobiles.

Applicants for the training must present certain qualifications of good conduct, education and health, and after a 3 weeks' probationary trial may be accepted as matriculated students. When the course is completed an official certificate of his qualification will be given the graduate. The result may be to create a demand for automobiles in Honduras. Only a few machines have ever been imported. Correspondence with the school should be in the Spanish language, if at all possible.

WICHITA, KANS., Aug. 22—Local automobile and accessories dealers have decided to promote an automobile, parts and accessories show to be held in the Forum in October.





Left—Plan view of Krit five-passenger touring car, showing center control. Note absence of side lights. Right—Driver's compartment of touring car, showing grouping of all instruments on a single plate illuminated by a small electric lamp. Note gasoline tank filler at right of instrument board. Stamina Is Needed

IT is more difficult to develop export business today in South America than it has been for some years, notwithstanding so many European factories are closed and that apparently South America will have to look to the United States.

Unfortunately, today South America is short on finances. Europe has been her banker, and when your banker goes back on you it is difficult to get money to purchase automobiles. America may first have to loan to South America much of the money with which we expect it to do business with us.

But even loaning money on these conditions is not an impossibility. These days call for the exercise of business courage, and the men and the organizations who put their money to this use will earn the trade they win and at the same time render patriotic service.

With the exception of commercial vehicles, the automobile industry is stagnant in Europe. The people do not want to purchase cars. They are hoarding their money. We must look elsewhere for markets, and although these markets may not be in their usual healthy condition, master efforts should be made to develop them. We must clear up the atmosphere in South America, wipe out the remembrance of extravagantly high prices on American cars, and of inadequate service for those already sold. This course is not specially remunerative, when considered in conjunction with the fact that some of the South American countries are declaring a 3 months' moratorium. But it is our task. Let us apply ourselves capably to it.

Racing Interests

LAST Saturday's road race on the 8-mile Elgin course once more demonstrated that the interest of the public in speed contests is not over. The attendance was greater than at any previous race in Elgin's 5 years of racing. This was not expected, many believing that the war situation would reduce the attendance perhaps 25 to 35 per cent. But the crowds were greater on both days than in previous years, and the public once more gave assurance that it is interested in speed contests, where competition is seen.

Although many attend races primarily to witness the spectacle of specially-designed racing cars travelling along the highway at upwards of 95 miles per hour, it must be remembered that these spectators carry home many impressions of the race that have a direct influence so far as their attitude towards automobiles goes.

For example: The car that makes the 300 miles without a single tire change, tells its lesson as compared with the slower car that makes five changes in the distance. Why does one car use more tires than another? This is the question on the lips of the interested owner-spectator. To him tires mean money. His annual tire expense is far in excess of his fuel and oil outlay. Perhaps the tire bill exceeds that of his garage. Little wonder, then, that he is vitally interested in a racing car that performs so admirably. To this spectator racing has a prodigious value. It has a direct dollar-and-cents interest to him.

But we can go further: Generally the racing car that is easy on tires, holds the road well, and travels 80 or 90 miles per hour over the roadway with scarcely a bounce, whereas other cars, changing tires and travelling little over 75 miles per hour, are bouncing from side to side. The car owner is interested in personal comfort. The car that holds the road appeals to him. It is more comfortable than the one bouncing from side to side. But in addition to being more comfortable it is safer. What more desirable factor of safety is there than that which causes a car to cling to the roadway?

Both safety and easy riding can be accomplished without a manufacturer entering in road or track races. One maker can learn the lesson through his racing team, and another can learn it in his engineering department. It is an open question which is the better, but it remains an undisputed fact that the roadway race is the great demonstrator to the public that many of our cars are yet far from the eventual so far as their ability to cling to the road is concerned.

It is most valuable to have these great object lessons, such as afforded by contests, where the public can have these merits in car construction demonstrated to them convincingly.

Downward Tendency in Tires —Companies Renew Old Prices

Supply of Crude Rubber in Sight Still Low But Market Recedes from Last Week's High Level

NEW YORK CITY, Aug. 25—The tire situation shows an appreciable improvement. Prices in several instances have fallen back to list and the present tendency is downward rather than upward.

Goodyear, which led the advance with 20 per cent., fell back to list Tuesday, August 18, with the explanation that it had secured means of obtaining crude rubber.

Empire followed August 20 by removing its advance of 12½ per cent., and the Mohawk company and the Miller Rubber, both of which had advanced 15 per cent., returned to the old list August 20.

Sterling has stated that it does not expect to advance.

The crude rubber situation remains much as it was, according to Henderson & Korn, rubber brokers, New York City, with little immediate prospect of material relief. Some rubber has been received in this country from South America in Brazilian ships, and some plantation grade has been received from London. The total, however, is negligible in comparison to what would ordinarily be received.

Para went to $1.12 and plantation to $1.10 immediately after the European war broke out, but these prices have fallen considerably. Para is now quoted at about 90 cents a pound and plantation at 75 to 80 cents, although there is little of either available. A small quantity of plantation from London sold as low as 72, but is not indicative of market conditions. Shipping and exchange, the prime causes of the shortage, show little improvement.

One hundred employees at the Hartford, Conn., plant of the United States Rubber Co., who were laid off when the war opened, have been taken back; the company expects an increase in business.

S. A. E. European Trip Postponed Indefinitely

NEW YORK CITY, Aug. 25—The Society of Automobile Engineers has postponed its second European trip indefinitely. The sailing date had been set around October 10 and the first stop was to have been Paris, but present war conditions have brought forth the postponement. The trip, as outlined, extended through France, Italy, Switzerland, Germany and England.

Colonies Are Buying Cheaper Cars

WASHINGTON, D. C., Aug. 22—Shipments of motor cars and parts, except engines and tires, to the noncontiguous territories of the United States during various comparative periods, are shown in figures compiled by the federal bureau of statistics. During June last 14 motor cars, valued at $13,737, and parts valued at $750, were shipped to Alaska, as against 8 cars, valued at $7,585, and parts, valued at $931, shipped there during the same month of last year. During the fiscal year ended June, the shipments of cars increased from 16, valued at $18,435, in 1913, to 54 cars, valued at $60,930, in 1914. The shipments of parts increased from $3,020 to $7,505.

Sixty-three motor cars, valued at $59,199, and parts valued at $7,040, were shipped to Hawaii in June last, while in June a year ago the shipments amounted to 54 cars, valued at $70,413, and parts valued at $6,172. During the fiscal year the shipments of cars decreased from 718, valued at $1,182,166, in 1913, to 701 cars, valued at $841,458, in 1914. Shipments of parts likewise decreased in value from $107,640 to $85,813.

Porto Rico received 19 cars, valued at $17,781, and parts valued at $4,456 from the United States in June last, as against 16 cars, valued at $24,729 and parts valued at $7,114, in June a year ago. The shipments of cars decreased from 323, valued at $406,440, in 1913, to 291 cars, valued at $320,680, in 1914, while the shipments of parts decreased in value from $93,813 to $70,025.

During June last 42 cars, valued at $45,646, and parts valued at $6,605, were shipped to the Philippines, while in June, 1913, the number of cars shipped was 94, valued at $105,919, together with parts valued at $7,195. The car shipments increased from 560, valued at $668,849, in 1913, to 652, valued at $761,980, in 1914, while the shipments of parts increased from $53,434 to $69,933.

Buick 1915 Schedule of 40,000 Cars To Stand

FLINT, MICH., Aug. 24—According to president Charles W. Nash, of the Buick Motor Co., the original plans of the company to build 40,000 Buick cars for the season of 1915 will be carried out notwithstanding the war. More than 5,000 men are now employed at the plant and the average daily output is 230 cars. The total value of the 1915 output will be worth about $42,000,000.

While the European export business will be non-existent, President Nash thinks that other markets will be able to take care of the American made cars.

Peerless 48 Only Six Next Year

CLEVELAND, O., Aug. 26—The line of large six-cylinder cars produced by the Peerless Motor Car Co. is continued for 1915 by the 48-Six which may be had in an open touring car and a limousine of standard type. In addition a wide variety of special cars fitted to the individual taste of the purchaser may be built on specification.

Convenience has been improved by the adoption of the new style of instrument board in the front compartment which places everything that needs to be touched within easy reach of the driver's hand.

Most important among the many minor mechanical changes that have been made in the car this year is the adoption of the spiral bevel gear in the rear axle. A constant level gasoline tank holding about a gallon is mounted under the cowl to supply an even pressure upon the carbureter under all conditions. The screen in the carbureter has been made removable so that it can be easily cleaned. Dry cells have been provided for emergency starting in winter. A new style of open wiring has been provided for accessibility and to improve the electrical efficiency the single wire system for both starting and lighting with separate fuses for the different circuits, has been adopted.

This year's open car is fitted with a touring body. It is exceptionally wide and spacious and provides room for carrying seven passengers in the greatest comfort. Folding seats of a new and exclusive Peerless design are used for the first time. These are more comfortable than any that have previously been available.

The side lamps have been removed from the dash and placed in the windshield filler board. A new type of glass front has been adopted which has a handle that makes it easy to fold.

The limousine follows the general lines of last year's body of the same type with some improvements in appearance. The front of the roof has a more pronounced curve and the quarter lights in the driver's compartment have been omitted. This leaves the view on either side open.

Windows throughout the car are of the sashless marine type and are fitted with much improved window lifts. All toilet cases and other interior equipment are mounted in and flush with the walls. Two types of auxiliary seats may be had: the special Peerless folding type which disappears into the front wall of the rear compartment when not in use, or the swinging type which folds against the side wall.

Interior lighting has been improved by the adoption of oval corner lamps and a large dome ceiling lamp.

In addition to the standard body types the Peerless Motor Car Company will always undertake the production of cars of special design containing features that are especially desired by the customer. Many extremely handsome cars have been produced in this way. This year special bodies of the Berline limousine, landaulet, Sedan roadster and torpedo types have been designed and can be specified by the purchaser who desires them.

The beetle decked roadster will carry three passengers on the main seat and a fourth upon a folding seat which is ordinarily carried under the deck of the car. The driver's part of the large seat is set forward about 9 inches so that the passengers may have the greatest possible freedom of movement. The five-passenger torpedo is fitted with a divided front seat which permits the passengers to pass from the front compartment to the tonneau without leaving the car. The Sedan also is fitted with divided front seats. It has only two doors, one on the right and the other on the left side of the tonneau.

1914 Deliveries Too Slow for Milwaukee Dealers

Dealers Report Increases in Business from 50 to 250 Per Cent.—Majority Felt a Shortage in Cars

MILWAUKEE, WIS., Aug. 21—With but few exceptions, Milwaukee motor car dealers did the largest business in the history of the local industry during the period from August 1, 1913, to August 1, 1914. The increases range anywhere from 50 to 250 per cent., and in most instances would have been considerably larger but for the fact that dealers could not obtain all of the cars they were able to market. A shortage is reported by more than 85 per cent. of all dealers. The other 15 per cent. consists of that class of dealer who handles approximately the same number of cars year after year and by reason of their peculiar circumstances are content to sell only that many and are not out to make records.

Books have just been closed on the fiscal year's business and show a most gratifying situation, particularly so in view of the unsettled state of business during practically all of the period.

Ford, of course, takes the lead, both in quantity of sales and percentage of increase. The Hickman-Lauson-Diener Co., Milwaukee, state agent, has disposed of 5,400 cars since October 1, 1913. Its fiscal year ends October 1, and there seems to be no doubt that the concern will make a 100 per cent. increase over the corresponding period a year ago, when 3,000 cars were marketed. It is only a question of getting cars.

Buick reports a 100 per cent. increase in sales through the Milwaukee branch, 150-160 Wisconsin street. M. J. Monson, manager, states that the 1914 allotment was absolutely sold out March 11, and no sub-dealer in the state has had a car to sell since May 1. What is more, the Milwaukee branch on August 1 had booked orders for 482 of the 1915 models and daily there are new buyers clamoring for more.

A like situation is reported by the Reeke-Osmond Motor Car Co., Milwaukee, which handles most of southern Wisconsin for the Thomas B. Jeffery Co., Kenosha. Business up to August 1, 1914, was 85 per cent. better than for the preceding period, and up to this time the company has booked orders for more than 325 cars of the 1915 type.

The Hoppe-Hatter Motor Co., 539 Broadway, Chalmers, Saxon and Rauch & Lang electric, reports an increase of 100 per cent. in electric vehicle sales and better than 50 per cent. in gas cars. Orders booked ahead are much larger than a year ago, and the only thing the firm is concerned about is getting enough cars to fill requirements.

A 50 per cent. increase is also reported by the Milwaukee branch of Cole Motor Co., 188 Eighth street, and Manager F. E. Tabbert says this could have been increased indefinitely if the factory had been able to supply enough cars.

A shortage of Reo cars is reported by Curtis Automobile Co., 142 Eighth street, which experienced a 33 1-3 per cent. increase, and was sold out long before August 1.

Frank J. Edwards, manager of the KisselKar Co., 178-180 Seventh street, did a business that was 50 per cent. better than the previous year and until 1915 goods arrived booked more orders for future delivery than at any time since the business was established.

Mitchell Automobile Co., 528-532 Broadway, branch of the Chicago wholesale and retail house, is able to report only a 25 per cent. increase in Mitchell business, but this was due to its inability to get more cars. Briggs-Detroiter being more liberal, the Milwaukee house was able to swell its percentage of increase on Detroiter business nearly 200 per cent. This is for the entire state of Wisconsin territory, while its representation of the Mitchell covers only three counties, Milwaukee, Waukesha and Ozaukee.

Schreiber-Boorse Motor Car Co., 180 Fifth street, reports a 50 per cent. increase on Locomobile and Hudson business. Both lines were dropped August 1, and the National and King substituted. Bookings already made indicate an exceptional increase during the coming year, although it is hardly fair to make comparisons of this kind.

An increase of 57 per cent. in Stutz business and 150 per cent. in Overland sales is reported by George W. Browne, Broadway and Biddle street. Browne's requisition for the new Overland Six and the allotment of the $1,075 model means even a larger percentage of increase during the coming season.

The Milwaukee branch of the J. I. Case T. M. Co., at 493 Broadway, did a 50 per cent. better business than during the previous year. The branch is under the direction of the Madison district office, which reports an even larger percentage of increase.

Moline sales were not so large as a year ago, but this is due to the smaller allotment given to the Wait Automobile Co., 222 Fourth street, state agent, by reason of the adoption of the Knight motor and heavy increase in price. William J. Wait said the concern could have disposed of at least 25 per cent. more if the cars could have been granted by the factory. The 1915 allotment has been increased that much.

W. W. Burgett, manager of the Stanley Steamer Co., Fourth and Prairie streets, says he sold twice as many 1914 cars as 1913 models. He had no difficulty in disposing of all the cars the Stanleys could give him. He has recently taken on the Lewis Six and has booked orders to cover all of his 1915 allotment.

The McDonald Motor Car Co., 239 Wisconsin street, reports a 25 per cent. increase in Lozier business. The concern has never experienced any trouble in disposing of the limited number of cars it can get from the Lozier factory and its shortage was greater this year than last.

The American Automobile Co., 187 Wisconsin street, state agent for the Pierce-Arrow, sold just as many cars as a year ago and as it has every year since it took the agency. No effort is made by this concern to break records, its allotment being the same year after year.

Cadillac sales increased 40 per cent., which was the percentage of increase in the 1914 allotment. Jonas Automobile Co., Eighth and Wells streets, has increased its 1915 requisition about the same percentage and expects to meet with the same shortage it has year after year.

The Chase Motor Truck Service Co., 2602-2606 North avenue, increased its 1914 sales 250 per cent. over 1913. Louis Pauly, manager, states that if the cars could have been got from the factory the increase would have amounted to not less than 300 or 350 per cent. Especially in the grocery trade is the Chase popular and Mr. Pauly expects a much larger allotment for 1915, so that his sales record will probably be the same during the coming year as last.

There has been no let-up in purchases since August 1, and there is every indication that the prosperity of 1914 will be duplicated during the coming year. If anyone can doubt the reports of Milwaukee dealers, it is only necessary to study the record of 1914 motor car registrations in the state of Wisconsin. On December 31, 1913, the Wisconsin registration by private owners was 34,646. On August 1, 1914, the registration had passed the 51,000 mark. Registrations expiring at the close of each calendar year, there are no duplications to swell the total. At the present ratio of gain, Wisconsin will show a total 1914 registration of 20,000 more than 1913, or nearly 55,000.

Buick Employes Plan To Eliminate Waste

INDIANAPOLIS, IND., Aug. 19—The employes of the Indianapolis branch of the Buick Motor Co. have organized the Buick Efficiency Society of Indiana whose slogan is: "All together all the time," and whose purpose is to promote higher efficiency among all Buick employes in all matters concerning or interesting motoring.

There are four classes of members, the first being the active members or employes of the local branch; the second membership consists of associates who are the dealers and sub-dealers within the territory looked after by the local branch; employes of dealers and sub-dealers make up the third class, or student members, while the fourth class, or honorary members, is made up of Buick owners.

Among the various important matters which will be taken up by the society is the problem of eliminating waste of materials and expenditures.

Blue Book Establishes New Service Bureau

NEW YORK CITY, Aug. 24—A new touring service bureau has been installed at both the New York and Chicago offices of the Automobile Blue Book Publishing Co. for the free and exclusive use of owners of the 1914 Blue Book.

Any owner of a current issue of the book is entitled to the free use of this Bureau for any kind of advice on any contemplated tour. This service covers the entire territory covered by the five volumes of the book—viz., all of the United States and Southern Canada.

General Motors Made 58,000 Cars in 1914

NEW YORK CITY, Aug. 24—During the fiscal year ended July 31, 1914, the General Motors Co. manufactured approximately 58,000 cars compared with about 55,000 in 1913.

It is understood that the balance of net profits for the 1914 fiscal period will run about 40 per cent. on the $16,476,000 common stock. This is substantially the same as in the 1913 year.

The export business will not suffer greatly as a result of the war. Only 10 per cent. of the total sales are foreign, and if it were all cut off the loss to net would not be a weighty matter.

Sales manager W. K. Chilcott states that sales made by the G. M. C. Truck Co. for the last half of the fiscal year, ending July 31, 1914, exceeded the same period in 1913 by 44 per cent. Sales for the entire fiscal year ending July 31, 1914, exceed the preceding year 33 per cent.

Sales for July, 1914, exceeded July, 1913, by 137 per cent. Sales for July, 1914, exceeded June, 1914, the record-breaker, 8 per cent. The term sales as used above does not mean orders received, but actual, bona fide deliveries of new models.

The number of dealers handling G. M. C. trucks is 232 per cent. greater than on January 4, 1914. With 32 per cent. less productive labor and 49 per cent. less non-productive labor, the company built 56 per cent. more trucks in June, 1914, than in June, 1913.

Helena Dealers Sell 150 Cars in 1914

HELENA, MONT., Aug. 18—Although every one of the local dealers has received literature about the 1915 models few have received their showroom models and all are trying by all means to get them as quickly as possible, as the business outlook is the brightest ever experienced.

The 1914 business year may now be considered closed since the announcements for the 1915 have been appearing and people do not want to know anything more about this year's cars. It is estimated that 150 to 200 cars were sold all told by the dealers.

The Western Auto & Supply Co., which handles the Ford had contracted to sell fifty of these cars in 1914 and up to date sold sixty-eight, the business being especially good during the last few weeks. The T. C. Power Co., which sells the Buick and Packard disposed of fourteen of the former since March and quite a few of the high priced Packards, which is good business considering that the company only has the western part of the state as its territory. H. La Chapelle, who has the state agency for the National and Apperson is well satisfied with his sales thus far. A very large number of Mitchell cars have been sold by A. D. Mitchell who handles them. While James Walker, the father, runs his grocery store, Edwin Walker, the son, looks after the sales of the Detroiter and Jackson cars of which a goodly number were sold during the year. Probably more Franklin cars were sold during the last 6 months by the Swendeman Automobile Co., than during any previous year. The company has the selling right for Broadwater, Jefferson, Lewis and Clark, Meagher and Powell counties.

Wilkes-Barre Agents Sold 818 Cars in 1914

WILKES-BARRE, PA., Aug. 25—Automobiles to the number of 818 have been sold this season by the dealers of Wilkes-Barre and its immediate environs. They range in price from $395 to $5,000, the total valuation being estimated at about $2,000,000. The population in the districts represented by the owners of the cars is about 150,000, which would mean one car for every forty-six families, using the average of four people to a family.

British Engineers' Society Changes Address

LONDON, S. W., ENGLAND, Aug. 20—The address of the Institution of Automobile Engineers has been changed to 28, Victoria street, Westminster, London, S. W.

N. Y. Hupmobile Agent Gets Newark

NEW YORK CITY, Aug. 24—Charles E. Riess & Co., the New York City agent for the Hupmobile car, will open a branch in Newark, N. J., at 373 Central avenue, the same place occupied by the former Hupmobile agency. A service station will be maintained at that location and a complete line of parts will be carried in stock.

Red Head Platinum Point Plug Is $2

NEW YORK CITY, Aug. 25—In the two-color page advertisement in THE AUTOMOBILE for August 13, the list price of the Red Head platinum point plug was inadvertently quoted as $1. This is the price of the regular Red Head plug. The platinum point plug lists at $2.

Wood-Wire Wheel Test Is Pennsylvania Tire Triumph

After 60,772 Miles "Little Is Actually Determined Except Staying Qualities of Tires," Says Report

NEW YORK CITY, Aug. 22—Completing 60,772 tire-miles, the test held for the Pennsylvania Rubber Co. by the Automobile Club of America for the purpose of denoting the relative merits of wire and wood wheels, as related to tire wear, has ended with little actually determined except the staying qualities of the pneumatic tires employed. The test was held under the supervision of Herbert Chase, laboratory engineer of the club.

The test started on March 31 when two new Lozier fours left the Automobile Club of America, one equipped with wood wheels and the other with wire. The cars were operated over the roads of New York City and vicinity until the Pennsylvania vacuum cup tires with which they were fitted wore out. Altogether there were nine tires used in the test, one of which did duty on both the wire wheel and wood wheel car, and therefore cannot be considered in making up resulting figures.

On the wood wheels the four tires which went throughout the test made 5,700, 7,500, 8,940 and 10,164 miles, an average of 8,078.

On the wire wheels the tires made 5,820, 4,300, 9,220 and 6,540 miles. This gives an average of 6,107 miles. The tires were frequently changed from wheel to wheel on both cars.

On the surface this would seem to give an enormous difference in favor of the wood wheels, but such is not the case by any means, as the tires on the wire wheels were subject to accident in the early periods of the run, thereby causing them to blow out sooner than would have been the case were they subject to ordinary wear. In fact, out of the nine tires used, but two perished through being worn out, one of these traveling 10,164 miles and the other 9,228. One of these was on the wood wheel and the other on the wire, showing a difference that cannot be compared owing to the fact that it was a single isolated instance, offering no basis for accurate comparison.

The ninth tire traveled 2,660 miles, at which time it blew out, owing to a cut it had received at the end of the 1,040th mile. As this tire had traveled this distance on the wood wheel, and after being repaired had been transferred to the wire wheel car, it cannot be reckoned in the comparison of mileages.

The Pennsylvania Rubber Co. entered into this test with the idea of demonstrating that a guarantee of 4,500 miles for its casings was not too high. Taking the average mileage of all nine tires, an average of 6,754 miles per tire was covered. The weight of the wood wheel car was 4,150 pounds, and of the wire wheel 4,050 with passenger load.

Outside of the value of the figures obtained on the mileage of the tires, which were secured from the stock of different dealers scattered about the country and which were purchased by the engineering department of the Automobile Club of America, the fact which is really brought home by the tests, that only two of the nine tires perished through being actually worn out; the others were all subject to cuts and bruises which might have occurred at any time during their life and which were subsequently the causes of their failure. In fact, one of the tires was cut and bruised by a sharp stone at 1,040 miles, and although repaired as was allowed under the rules of the test, it blew out at the point of injury at the 2,660-mile point.

No doubt the number of cuts and bruises sustained would be less if the car were run over dirt roads. A summary:

Tire No.	Wheel	Miles Traveled	Cause of Elimination
1	Wire	9,220	Worn out; never deflated.
2	Wood	8,940	Cut by sharp stone at 7,610 miles; blew out.
3	Wood	7,500	Bruised; blew out; never deflated.
4	Wire	6,540	Cut by sharp stone at 3,350 miles; blew out at point of injury.
5	Both	2,660	Cut and bruised by sharp stone at 1,040 miles; blew out at point of injury.
6	Wood	5,700	Punctured by screw at 3,290 miles; blew out at point of injury.
7	Wire	4,300	Cut by sharp stone at 2,390 miles; blew out at point of injury.
8	Wire	5,820	Cut at 5,690 miles; blew out at point of injury.
9	Wood	10,164	Worn out; never deflated.
Total miles		60,784	Average miles per tire, 6,754.

127 Detroit Cos. Incorporated in 7 Months

DETROIT, MICH., Aug. 20—The Board of Commerce of Detroit has published some statistics concerning local business conditions during the first 7 months of the year as compared with the corresponding period of 1913. It shows among other things that thus far this year 127 companies have been incorporated, or 8 less than last year, but the total capital stock subscribed is $8,110,400 or $4,331,820 more than during last year's first 7 months. In this increase of capital stock the automobile industry is far ahead of all others inasmuch as one single concern, Dodge Brothers, was incorporated for $5,000,000.

The total value of the automobiles, parts and accessories exported up to the end of July was $5,004,245 or $86,607 less than for the similar period last year, and represented 16.1 per cent. of the total value of all exports from Detroit, while last year's percentage of the automobile industry in the total exports was only 12.6 per cent.

Armored Autocars for European Powers

PHILADELPHIA, PA., Aug. 25—Armored steel automobiles for use by the European powers engaged in war are being manufactured in this city by the Autocar Co. and will be shipped from its plant at Ardmore as soon as completed. The firm is said to work with the knowledge of Secretary Bryan.

Cars have been sold to nations on each side of the conflict. One order includes fourteen cars for the British Government. These cars are to be shipped to private individuals in Canada and thence reshipped to England.

Negotiations with France, Russia and Greece have also been entered into and it is said orders for 1,000 more cars have been placed by the various powers.

Market Reports for the Week

This week's markets experienced a general advance in prices. Both Bessemer and Open-Hearth steels rose $1.00 per ton. Electrolytic copper rose $0.00 1-8 per pound. The larger exports of copper to Great Britain in the last few days have encouraged the producing interests in this city to hold a little more firmly, but the larger supply abroad has resulted in lower prices there. The domestic market continues dull with small demand from domestic consumers. The supply of copper is more than ample to meet current requirements and notwithstanding the decrease in output, current production seems to be in excess of current requirements. Lead is quiet but firmer. Tin has come down to normal prices again. On Tuesday it was quoted at $39.50 per 100 pounds. The opening price was $49.00, leaving a $9.50 cut in price for the week. The demand for tin from domestic consumers is light. Warehouse supplies are a little more concentrated, but more tin is being offered for future delivery. On Tuesday, a steamer from London arrived with 100 tons of tin, while another ship from Rotterdam brought 10 more tons. Rubber has come down to $0.80. Manufacturers are still holding aloof pending developments.

motorists of the state is thus returned to their home counties to be used for the permanent improvement of highways. Milwaukee county, naturally, has the largest drawback. There were registered from Milwaukee county 8,602 motor vehicles, at $5, or $40,010; 130 dealers at $10, or $1,300; 1,892 motorcycles at $2, or $3,794, a total of $48,069 received. The return to Milwaukee county is $33,213.94. Dane county, seat of the state capital, has a drawback of $10,519.23; Rock county, $6,655.04; Fond du Lac, $8,074.26; Racine, $5,665.90; Sheboygan, $5,541, and Winnebago, $5,116.55.

Wire Prices Advance $1 a Ton

NEW YORK CITY, Aug. 25—The American Steel & Wire Co. has announced a price advance of $1 a ton on all products to take effect immediately. This is in line with the advance of $1 a ton made by the Youngstown Sheet & Tube Co.

According to the local wire wheel dealers and manufacturers this will have no effect on the prices of wire wheels.

Approve Claims of 1,641,382 Against Pope Co.

BOSTON, MASS., Aug. 24—Claims aggregating $1,641,382 against the Pope Mfg. Co. have been approved by the receivers, according to the first report filed in the United States District Court here. This does not include a claim for $1,000,000 filed by the Empire Trust Co. of New York as trustee for the noteholders, which the receivers have approved for only $5,000.

The total assets on June 30 last were valued by the receivers at $1,562,895. Accounts payable on that date aggregated $60,595.

Since their appointment last November the receivers have sold 21,062 motorcycles and 40,602 bicycles up to June 30 last. They recommend the sale of the plant at Westfield, Mass., at public auction and as soon as an upset price can be fixed they will apply to the court for permission to sell.

Texas Fire Insurance Restricted

AUSTIN, TEXAS, Aug. 24—In a ruling to the State Department of Insurance, the Attorney-General's Dept. has held that a mutual fire insurance company is not authorized to avail itself of the provisions of the law permitting such companies to insure automobile and other motor vehicles. This includes risks against loss or damage by fire, lightning, wind storms, hail storms, tornadoes, cyclones, explosions, transportation by land or water, theft and collisions.

Sparks-Withington Adds 50,000 Sq. Ft.

JACKSON, MICH., Aug. 24—The Sparks-Withington Co., Jackson, Mich., has just completed a structural steel and concrete building at the rear of its plant which gives it 50,000 square feet additional floor space for the exclusive use of nickel plating and shipping departments.

An improvement for facilitating in and out shipments, and relieving the men of the strain caused by heavy lifting, is a concrete pit 10 feet wide by 25 feet long, which permits the automobile trucks to enter freely, bringing the body floor of the trucks on a level with the cement floor, thus enabling the men to run the hand trucks directly to the material and overcoming the necessity of hoists.

Auto Wheel Company Elects

LANSING, MICH., Aug. 20—At the annual meeting of the stockholders of the Auto Wheel Co., the following were elected members of the board of directors: E. S. Porter, H. E. Bradner, Lawrence Price, J. C. Watzel, Elgin Mifflin, Harry P. Woodworth, all of Lansing, and Henry J. Campbell, of St. Joe, Mich. E. S. Porter remains president of the company; H. E. Bradner, vice-president and D. L. Porter, secretary-treasurer. The business year just ended has been satisfactory and the outlook for 1915 is promising. The business of the company has been steadily increasing and from a small factory with only a dozen workingmen it has become a concern which now employs about 100 men.

German Cars Predominated at Swedish Show

MALMOE, SWEDEN, Aug. 24—At the exposition which opened in Malmoe, Sweden, May 15, and which it is reported was closed a week after war between Germany and Russia was declared, only four countries exhibited their products in the 117 buildings on the exposition grounds. There were 1,225 Swedish exhibitors, 668 German, 241 Danish and 151 Russian. The German automobile industry took up one-fifth of the total number of German exhibitors as every car, parts and accessories manufacturers of Germany is reported to have been represented. In fact, it is stated in German publications that never before in the history of the German automobile industry was that country so thoroughly represented. More than 150 complete German automobiles were on display.

Garage Men and Dealers to Meet in Minneapolis

MINNEAPOLIS, MINN., Aug. 24—There probably will be several hundred retail automobile dealers and garage owners in this city September 10 and 11 when the first convention of the Retail Automobile Dealers Assn. of the Northwest will take place. The 2-day affair will be a composite of pleasure and business, it being the object of the convention to be a go-between for the retail and wholesale trade. The association was organized for the purpose of standardizing the retail automobile industry and receives the co-operation of the retail dealers and garage men, on the one hand, and the wholesale accessory and supply houses, distributors and manufacturers, on the other hand. The officers of the association are: C. W. Jewett, Bemidji, Minn., president; G. A. Lewis, Mankato, vice-president; P. C. Frazee, Pelican Rapids, secretary-treasurer.

An Electric Vehicle Day Throughout America?

NEW YORK CITY, Aug. 22—An Electric Vehicle Day, staged simultaneously in a large number of American cities, is being considered by the Electric Vehicle Association of America. It was suggested by Robert Montgomery, commercial manager of the Louisville Gas & Electric Co., Louisville, Ky., and such a day may be held in that city this season. The national project, however, may not mature until next summer.

Montgomery's suggestion is that a certain day be set aside, preferably a holiday, and that parades and demonstrations be held everywhere on that date. Prizes for various competitive features would be offered by the central stations and newspaper and poster advertising would center public attention upon the electric vehicle.

Warships To South America As Sample Cases

NEW YORK CITY, Aug. 24—A resolution was introduced recently at Washington, D. C., by Senator Weeks, of Massachusetts, calling upon the Secretary of Commerce for information as to the cost and feasibility of sending six vessels of the United States navy with samples of American products to South American ports for the purpose of encouraging trade between the United States and the South American republics.

H. T. Sigwalt with Federal M. T. Co.

DETROIT, MICH., Aug. 25—A number of important changes have been made in the organization of the Federal Motor Truck Co. H. T. Sigwalt, formerly with the Fort Wayne Corrugated Paper Co, Fort Wayne, Ind., has joined the company as advertising manager. R. G. Hargreaves, well-known as an engineer, and who was formerly with the Cadillac Motor Car Co., Detroit, has been appointed transportation engineer.

In the sales department the following appointments were made: C. T. Cary, formerly with the Peerless Motor Car Co., Cleveland, O., as manager of its truck department, is now Eastern district sales manager. E. W. Hurd, formerly with the J. D. Whitmann Co. is district manager for the territory comprising Michigan, Ohio and Pennsylvania. L. L. Barnes, formerly with the Chalmers Motor Co., Detroit, is now southeastern district sales manager. Charles Case, who was with the Oliver Motor Truck Co., Detroit, has become southwestern district sales manager.

U. S. Exports Began to Fail in June

WASHINGTON. D. C., Aug. 22—In addition to the general export figures published last week in THE AUTOMOBILE, the following detailed figures show the exports of commercial and pleasure cars, together with parts, during June and the fiscal year ending June 30, 1914, with comparative figures:

	JUNE—				TWELVE MONTHS ENDING JUNE—			
	1913		1914		1913		1914	
Automobiles	No.	Value	No.	Value	No.	Value	No.	Value
Commercial	115	$167,391	90	$120,257	993	$1,737,141	784	$1.181,611

At Last an A. A. Is Formed in Oklahoma

OKLAHOMA CITY, OKLA., Aug. 25—Automobile owners and dealers have perfected a state-wide organization known as the Oklahoma Automobile Assn. Members of the association met at Oklahoma City recently to elect officers and discuss plans for preparing road maps and logs of every county for the owners and tourists visiting in the southwest. Short speeches were made on the question of good roads legislation and plans were laid for concerted effort to procure a revision of the present road laws of the state. A committee was chosen to obtain rooms for offices for state headquarters to be maintained here where residents and visitors can obtain reliable information concerning routes and road conditions.

Officers were chosen as follows: C. B. Shafer, Cushing, president; F. H. Tidman, Oklahoma City, first vice-president; Frank Kraft, El Reno, second vice-president; Directors: J. D. Butts, Cherokee; A. C. Trumbo, Muskogee; J. M. Berry, Tulsa; J. W. Deam, Geary; A. H. Purdy, Bristow; E. I. Eckelkamp, Eufaula, and W. H. Vincent, Foss. F. E. Harkness of Oklahoma City was chosen state secretary.

N. A. A. M. Appoints Committees for Year

NEW YORK CITY, Aug. 24—Appointment of committees to handle various branches of the industry has been made by the National Automobile Chamber of Commerce.

The new appointments just announced by Charles Clifton, president, are as follows: Traffic committee, W. E. Metzger, Argo, chairman; E. R. Benson, Studebaker, and R. E. Olds, Reo.

The patents committee: C. C. Hanch, Marmon, chairman; W. H. Van Dervoort, Moline; William T. White, White, and W. C. Leland, Cadillac.

The commercial vehicle committee: Windsor T. White, White, chairman; Alvan Macauley, Packard, and H. Kerr Thomas, Pierce.

The electric vehicle committee: H. H. Rice, Waverley, chairman; F. R. White, Baker, and W. C. Anderson, Anderson.

The good roads committee: R. D. Chapin, Hudson, chairman, and S. D. Waldon, Packard.

The legislative committee: H. H. Rice, Waverley, chairman; G. H. Stilwell, Franklin, and J. I. Farley, Auburn.

The show committee: George Pope, chairman; H. O. Smith, Premier, and W. C. Leland, Cadillac.

May Have Two Truck Conventions

NEW YORK CITY, Aug. 25—Whether there will be two truck conventions or one this fall will doubtless be decided at the regular monthly meeting of the Board of Directors of the National Automobile Chamber of Commerce, September 2.

Two weeks ago the Motor Truck Club of America announced plans for a motor truck convention to be held October 7, 8, 9, and 10 in Detroit and President George H. Duck of the Motor Truck Club invited the National Automobile Chamber of Commerce to co-operate with it in conducting a convention which will bring together manufacturer, dealer and user.

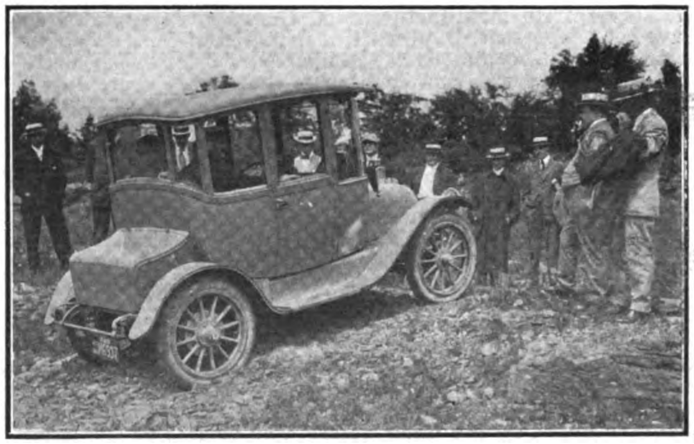
The Chamber of Commerce had been planning for some time on holding such a convention and at the summer meeting of the directors, held at Christmas Cove, Me., a plan was endorsed for a truck convention to be held sometime in the fall, the date and place to be selected at the September meeting.

The result may be a single convention combining all interests in the truck field or there may be two independent meetings. In the meantime the two organizations are conducting their plans independently, each having prepared a tentative program.

N. Y. Division of Electric Veh. Assn. Formed

NEW YORK CITY, Aug. 20—The New York City members of the Electric Vehicle Assn. of America met tonight at the auditorium of the Consolidated Gas Bldg., and formally inaugurated the New York division of that association with the following officers: chairman, Harvey Robinson; vice-chairman, D. C. Fenner, and secretary, D. F. Tobias. The executive committee consists of the above and the following: W. C. Andrews, T. C. Martin, S. W. Menefee, Nathaniel Platt, F. S. Sampson, F. W. Smith, S. G. Thomson, C. A. Ward and C. Y. Kenworthy.

The new branch will start off with a membership of nearly 200, which is the largest local in the country. Chicago has 120, Boston 110 and Philadelphia about eighty. In all, the national organization has a dozen local branches at present, and a membership of almost 1,000.



Demonstration of new Buffalo electric before automobile men and electrical engineers

Buffalo Electric Makes Debut

BUFFALO, N. Y., Aug. 23—For the purpose of formally announcing the new Buffalo Electric, the Buffalo Electric Vehicle Company on Aug. 21 entertained several of the more prominent citizens of Buffalo together with representatives of the automobile and electric industry in Buffalo.

Starting from the offices of the Buffalo Electric Vehicle Company, the caravan made a trip of about nineteen miles out to the club house of the Buffalo Automobile Club where luncheon was served. On the trip stop was made on what is known as the Transit Hill—a hill of some length with an average of about 23 per cent. grade and practical demonstrations were made of the ability of the new car to climb the hill as well as demonstration of the fact that in going down the hill it is unnecessary to use brakes of any kind other than the motor. As described before in this new electric, the motor is used for all brake purposes, excepting coming to a dead stop and when coasting down hill or even around curves the motor is transformed into a generator and charges back into the battery.

After the luncheon very brief addresses were made by: A. G. Batchelder, Laurens Enos, A. A. Grey, and Howard L. Spohn.

Baker Electric Makes 130 Miles on 1 Charge

PHILADELPHIA, PA., Aug. 21—A new record for an electrically propelled car was established here yesterday when R. S. Pullen, sales manager of the Carroll A. Haines Co., 2212 Spring Garden street, agents for Baker electrics, and S. S. Pancoast, electrical engineer, drove a Baker electric from this city to Atlantic City, N. J., and return on one charge of the battery.

The total distance covered on the one charge was 130 miles. The car was equipped with a Philadelphia storage battery and averaged 15 miles per hour.

Gasoline at 10.3 Cents a Gallon in Kansas City

KANSAS CITY, MO.—The Sugar Creek Refinery of the Standard Oil Co. of Indiana is operating at the same capacity as before the outbreak of war in Europe. About 1,000 men are employed at this refinery now.

Gasoline is selling here at 10.3 cents a gallon, the lowest price in 4 years. There is strong competition between the Standard Oil Co. of Indiana and minor producers in the local market, and as a result prices have been forced down from 15.5 cents last April to the present level.

About a month ago the Cudahy Oil Co. announced its intention of allowing the members of the Kansas City Automobile Club 1-2 cent on every gallon of gasoline sold at its stations here for their good roads fund. A little later, the Standard Oil Co. of Indiana, here, followed this up with an announcement that this company would give four of the leading Kansas City charities 1-2 cent for every gallon of gasoline sold by it here in August. It is expected that the charities will receive between $2,000 and $3,000 from this distribution.

New York City gasoline prices are quoted at 13 cents. New Jersey prices are quoted at 11 cents.

In a war between the Standard Oil Co. and the Indiana Oil Co. at Goshen, Ind., the retail price of gasoline has been reduced from 18 cents per gallon to 9 cents. Every garage in the city became involved.

County Prizes for Fair Motor Attendance

INDIANAPOLIS, IND., Aug. 24—A new feature at the Indiana State Fair, to be held at Indianapolis the week of September 7, will be an automobile contest, which is being arranged for the state board of agriculture, which controls the fair, by the Hoosier Motor Club. This contest will be for thirteen counties in central Indiana, excluding the county in which Indianapolis is situated. The county having the largest number of cars at the fair, Wednesday, September 9 will be given $100; the county having the next largest number of cars on the ground will receive $65 and the third largest $25. The counties are to decide for themselves how the prize money shall be spent.

Two-State Tour Over Pikes Peak Highway

DENVER, COL., Aug. 20—A 635-mile reliability and sociability run is being made this week from Colorado Springs to Salt Lake City over the Colorado-Utah link of the Pikes Peak Ocean to Ocean Highway. Twenty cars, representing eight states, made the start, and after those unable to take the time for the entire run turn back there will still be about a dozen cars to complete the week's trip through the Rockies.

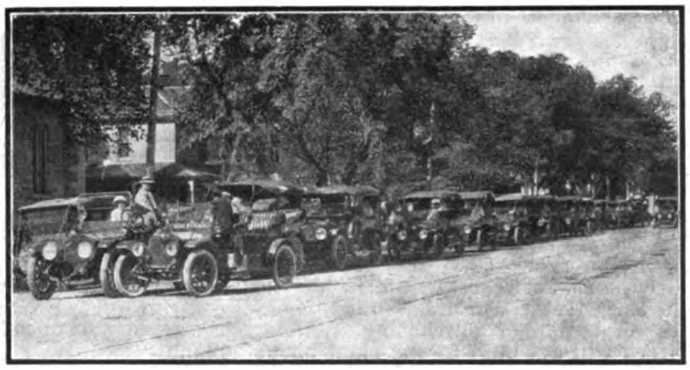
The run is expected to demonstrate the practical feasibility of this new picturesque route across the continent and through the heart of the mountains.

The road goes through Manitou, over Ute pass to Buena Vista and Leadville, then over Tennessee Pass at an altitude of 10,400 feet, where the new grade is only 4 per cent., and on through the splendid scenery of the Canyon of the Grand to Glenwood Springs, through the wild country across from Rifle to Meeker and on across the fertile Uintah Basin and the Utah plateaus to Vernal and Salt Lake City. Mountains, canyons, lakes, rivers and brooks are all along the way, and the road promises to attract a large per cent. of the transcontinental travel by motor.

Several Perfect Scores in Seattle Paper's Run

TACOMA, WASH., Aug. 18—Flying Canadian and American flags, sixteen out of the twenty-one cars entered in the Second Annual Post Intelligencer Tour completed, covering a distance of 593.9 miles in the State of Washington and the province of British Columbia, returning to the starting point, Seattle, on the evening of August 18.

The group at the demonstration of the Buffalo electric at Buffalo, N. Y.: Standing, left to right—1—J. P. Mallett, Engineer, Society for Electrical Development. 2—Henry D. Knox, F. W. Woolworth Co. 3—A. A. Grey, Managing Editor Electrical Review. 4—Richard O'Keefe, Secretary Automobile Club. 5—F. G. Peck, Engineer, Buffalo Electric & Vehicle Co. 6—John W. Van Allen, Wilson & Van Allen, Attorneys, Buffalo, N. Y. 7—Laurens Enos, Ex-President A. A. A. 8—John T. Steele, Organizer, Buffalo Electric & Vehicle Co. 9—H. B. Niblette, Goodrich Tire & Rubber Co. 10—W. A. Zimmerman, Sales Mgr., Buffalo Electric & Vehicle Co. 12—Dai H. Lewis, Secretary Automobile Club. 15—F. T. Turner, Editorial Department Buffalo Times. 17—Howard L. Spohn, Class Journal Co. 18—A. G. Batchelder, Chairman Executive Board A. A. A. 19—W. F. Fuqua, W. F. Fuqua & Co., Bankers, Philadelphia, Pa. Kneeling, left to right—1—E. J. Fouts, City Editor Buffalo Courier. 2—M. M. Wall, president Buffalo Automobile Club. 3—G. K. Rudolph, Managing Editor Buffalo Enquirer. 4—Dan Ferry, Editor Buffalo Motorist. 5—E. E. Denniston, General Manager Buffalo Electric & Vehicle Co. 6—Edward Deitzer, Advertising Manager Buffalo Courier. 7—Frank Bloomer, Assistant Editor Buffalo News



Start of the Colorado White sociability tour. This tour, which was detailed in The Automobile for August 20, started in Manhattan, Kan., and had for its objective the city of Pueblo, Col.

The first competing automobile to arrive was No. 16, a Chalmers, driven by Joe Thomas, and which duplicated its performance of last year. The Chalmers was closely followed by the Franklin with W. A. Wicks at the wheel. Other perfect scores were made by Harry D. Austin in a Metz; George Purdy, Buick; T. F. Barsby, Studebaker, and F. C. Sheraton in a Ford.

Hughie Hughes in a Maxwell "25" drove nearly the entire distance without an adjustment, but on the final day was unlucky in burning up a bearing in the connecting rod. The motor of the car had to be taken down, and for this the racing driver received a penalty of 408 points.

Novelty Racing in Denver Labor Day

DENVER, COL., Aug. 20—A revival of motor car racing in Denver will be witnessed on Labor Day, September 7, when one of the liveliest race meets ever staged in Colorado will be pulled off on the Overland Park course by the Denver Motor Club. The program will start with a race for Fords in a 10-mile dash all their own and finish with a 25-mile landscape-streaking event open to stock cars of all kinds. There will also be some novelty features of exceptional interest to motor car owners, and plans are also under way to put on an exhibition event of powerful racing machines.

The other amateur events, all of which carry prizes, will be as follows: 5-mile race exclusively for the old-timer cars built prior to 1909. Obstacle race requiring cars to dodge dummies, boxes and other obstacles scattered across the track, with a point against the driving score for every obstacle struck. 2-mile trouble race, requiring cars to stop in front of grandstand and change one tire at the end of the first mile. 15-mile open race for cars of not more than 35 horsepower.

The entries so far include several drivers noted for their daring and the meet promises to furnish plenty of thrills. The following will be among those in the final event of 25 miles: E. W. Swanbrough in a Lozier, Eddie Bull in a Franklin, Harry Ball in an Overland, Benny Knott in a Pathfinder, William Thorney in an Apperson, and Jimmie McDonald.

Two-Day Meet for Brighton Beach Sept. 5-7

NEW YORK CITY, Aug. 24—Two days of automobile racing instead of only 1 is scheduled for the Labor Day holidays at the Brighton Beach track. The matinee meet will open Saturday, September 5, and will be resumed on Monday, September 7.

The program for the opening day is to be made up of a number of small sprints, while on Labor Day will be the feature event, the Labor Day Sweepstakes, for a distance of 100 miles and for a purse of $1,000. This event is to be a class D free for all.

The majority of the star drivers who raced at Elgin have arranged to express their cars East in time to tune them up for the opening meet.

Cyclecar Race for Columbus

COLUMBUS, O., Aug. 24—Arrangements have been completed for a cyclecar race meeting to be held at the Columbus Driving Park, Sunday, August 30. The race meet will consist of about eight events ranging in distances from one mile to an hour race. Ralph S. Breckbill of the Buckeye Cycle Car Company of Columbus is receiving the entries which are coming in well. A. A. A. sanction has been applied for.

TWOMBLY Leases N. Y. Motor Factory—The Twombly Car Corp., New York City, has leased the plant formerly occupied by the New York Motor Works in Nutley, N. J., with an option of purchasing it. The concern will get busy at the plant about the middle of next month. It will manufacture light delivery wagons, taxicabs and town cars.

Will Build Taxicabs—Taxicabs built in its own factory will shortly be put in service by the Spokane Taxicab Co., according to announcement made by Manager G. E. Riegel, of Spokane, Wash.

1,000 Engers for 1915—President F. C. Enger, of the Enger Carriage Co., Cincinnati, O., announces that the company will build 1,000 cars during the coming year.

Acquires Imperial Wheel Plant—The Monroe Motor Co., Flint, Mich., recently incorporated for $250,000, to manufacture automobiles, has acquired the plant of the Imperial Wheel Co.

2,000 Sommers Motors for Allen—The Allen Motor Co., Fostoria, O., has contracted with the Sommers Motor Co., of Bucyrus, O., for 2,000 four-cylinder motors for its 1915 cars.

New Process Gear Adds—The New Process Gear Corp., Syracuse, N. Y., is taking bids for a case hardening building, 36 by 95 feet, three stories high with a basement, to be erected on Plum street.

Aluminum Co. Enlarges—The Aluminum Specialty Co., of Manitowoc, Wis., which recently added new capital, will erect a new plant, 60 by 200 feet, of brick and steel. It is to be ready for occupancy about September 15.

Besser Purchases Alpena Plant—The Besser Mfg. Co., Alpena, Mich., has purchased the plant of the defunct Alpena Motor Co., at a receiver's sale. The Besser company, which manufactures concrete mixing machinery, will operate the factory as an addition to the present plant.

Auto Products Co. Will Move—The Board of Trade of Canal Dover, O., announces that the Auto Products Co., Canton, O., will remove its plant to Canal Dover. An effort is now being made to sell $20,000 of the preferred stock of the company. It is expected the plant will be removed in about 60 days. The company manufactures automobile parts and accessories.

Largest American Diesel Engine Built—The Lyons Atlas Co., Indianapolis, Ind., has recently completed and shipped the largest Diesel engine constructed to date in this country. This engine is composed of four cylinders, 21 inches bore by 30 inches stroke, and is of the vertical, four-cycle type, rated at 600 brake horsepower with an overload capacity of 15 per cent., or 690 brake horsepower maximum.

Detroit Gear Co. Adds—A two-story brick building will be started within a few days as an addition to the plant of the Detroit Gear & Machine Co., 129 Franklin street, Detroit, Mich. The new structure will cost $22,000. The local concern started in business only 4 years ago with a capital stock of $100,000, which has since been increased to $150,000. The business has been steadily increasing and even a very satisfactory foreign trade has been worked up.

Hupp Makes New Additions—Work has been started on a large addition to the general office building of the Hupp Motor Car Co, Detroit, Mich. When completed, the offices will have about double the floor space which they now occupy and will be one of the finest and most modern office buildings in the city. One of the features will be a new and much larger dining room where the noon luncheons will be served, which have been found by the officials of the company, to be of the greatest aid in effecting close co-operation among the men.

Broc Organization Moved to Saginaw—The entire organization and equipment of the Broc Electric Vehicle Co., Cleveland, O., has been removed to Saginaw, Mich., owing to the recent consolidation of the company with the Argo Electric Co., Saginaw, and the Borland-Grannis Co., Chicago, Ill., into one concern known as the American Electric Car Co., with general headquarters in Saginaw. This company has established a service station at 1976 East 66th street in Cleveland, O., in charge of H. C. Young, formerly with the Broc company.

Blodgett Plant in St. Joseph—The Blodgett Rubber Co., Warren, O., will locate its plant in St. Joseph, Mich. The new concern was secured by the St. Joseph Development Co., which is to furnish a factory site and building which, under certain conditions, will become the property of the rubber company after 5 years. The Blodgett company manufactures a tire of non-puncture variety, under a patented process. W. E. Bryan, a Chicago attorney, is president of the company, and M. D. Wilber, secretary. It is expected to have the factory in operation in 60 days.

The Automobile Calendar

The Week in  the Industry

Motor Men in New Roles

ECCLESTON Apperson Sales Manager—Apperson Bros. Automobile Co., Kokomo, Ind., announces the appointment of J. B. Eccleston as general sales manager; Howard A. Bauer, assistant sales manager; J. H. Newmark, advertising manager, and Joe G. Roberts, general traveling representative.

Curtis Splitdorf's Boston Manager—The Splitdorf Electrical Co., Newark, N J., has appointed H. R. Curtis manager of its Boston, Mass., office.

Lebon Jeffery District Representative—M. F. Lebon has been appointed district representative for New York by the Thomas B. Jeffery Co., Kenosha, Wis.

Pickering Manager—L. C. Pickering has been appointed manager of the recently organized Grant Distributing Co., which has opened for business at 514 Grant avenue, Des Moines, Ia.

Canary Houk Chicago Manager—Dan J. Canary has become the manager of the branch of the George W. Houk Co. in Chicago, Ill. The branch is located at 2339 Michigan avenue.

Camp Chalmers N. Y. Sales Manager—A. Roy Camp has been appointed sales manager of the Chalmers Motor Co., of New York. He has been with the New York agency since its beginning in 1908.

Elkin Manager G. M.'s Chicago Branch—The General Motors Truck Co. has appointed Z. C. Elkin manager of the Chicago branch. He was formerly manager of the Thos. B. Jeffery Co.'s Chicago branch.

Paine Made Manager—Charles A. Paine has been made manager of Belcher & Loomis Co., Providence, R. I., succeeding Henry Paquin. He has been 3 years with the company and the change comes as a promotion.

Henderson KisselKar Executive—O. B. Henderson has been appointed vice-president of the Pacific Kissel Kar branch, Los Angeles, Cal. Previously he was general manager for the Baker Motor Vehicle Co., Cleveland, O.

Rutter Detroit Monarch Manager—L. Rutter has taken over the management of the Rutter. Raths & Theisen Auto Sales Co., 761 Dix avenue, Detroit, Mich., which handles the Monarch cars and conducts a service station.

Zimmerman Sales Manager—W. A. Zimmerman has been appointed general sales manager of the Buffalo Electric Vehicle Co., Buffalo, N. Y. Previously he was sales manager of the Mercury Motor Truck Co., Chicago, Ill.

Mollohan Switches to Buick—Charles Mollohan, 5 years credit manager of the *Daily Oklahoman* newspaper of Oklahoma City, has resigned his position to become identified with the city sales department of the Buick Motor Co.

Brown J. M. Special Representative—F. E. Brown has joined the staff of the H. W. Johns-Manville Co., New York City, as special representative to devote his attention to the sales development of the Noark service-meter protective devices.

Marshall Makes Change—William J. Marshall, formerly president of the Mercury Cyclecar Co., Detroit, has become general manager of H. Collier Smith, 815 Scotten avenue, Detroit, Mich., manufacturer of special sheet metal machinery.

Mauthe Batavia Rubber Representative—F. G. Mauthe, formerly manager of the Goodyear Tire & Rubber Co., in Newark, has become associated with the Batavia Rubber Co., of New York, as special representative in the State of New Jersey.

Henderson Canadian Regal Sales Manager—It is announced by the Regal Motor Car Co., Detroit, Mich., that R. P. Henderson has been appointed sales and advertising manager and Henry Nyberg production manager of the plant in Berlin, Ont., Canada.

Woodin Detroit Abbott Manager—T. C. Woodin, former eastern sales manager of the Abbott Motor Co., Detroit, Mich., has been appointed manager of the Detroit branch of the Abbott Motor Co., the salesrooms being at 467 Woodward avenue.

Birnie Joins Simplex—H. T. Birnie has joined the sales organization of the Simplex Automobile Co., New York City. He was formerly with the Packard Motor Car Co., that city. He succeeds F. H. Bowen, who has become manager of the S. G. V. agency in New York City.

Moore to Handle Rad-Fix—The Radiator Fix Co., Boston, Mass., has arranged with the William M. Moore Co., 1305 Sutter street, San Francisco, Cal., to handle the distribution of its product, Rad-Fix, in that territory. This product is a solution for repairing radiators.

Godbey Assistant Sales Manager—W. H. Godbey, Jr., formerly with the Memphis Motor Car Co., and also with the Ford Motor Co., Memphis, Tenn., has been appointed assistant sales manager of the Premier Sales Co., Memphis, Tenn., which handles the Premier, Oakland and Chevrolet cars.

Hughes Victor Parts Sales Manager—The announcement is made by sales manager W. R. Hughes of the Victor Auto Parts Co., Cincinnati, O., to the effect that in the future the products of the company will be sold direct by the factory instead of through Fulton McCutchan, formerly sales agent.

Dodge Bros. Make Appointments—Harvey Mack, with the Joy Bros. Motor Car Co., Minneapolis, Minn., has signed up for the Dodge car which is to be put in there in the near future. A. C. Templeton has been appointed district representative for Dodge Bros., Detroit, Mich. His district is Minnesota and North Dakota, and parts of South Dakota, Montana and Wisconsin.

Bush Studebaker Sales Manager—Vice-President Benson of the Studebaker Corp., Detroit, Mich., announces the appointment of W. T. Bush, formerly sales manager of a Detroit automobile agency, to be sales manager of the Studebaker Corp., of Canada, Ltd., Walkerville.

Garage and Dealers' Field

Purchase Hupmobile Agency—The Central Iowa Motors Co., Des Moines, Ia., distributor of the Hupmobile, has been purchased by Messrs. W. S. Adams, F. E. Card and H. R. Brown. The business will be continued under the same name.

Flint Sheet Metal Co. Organized—The Flint Metal Specialty Co. has been organized in Flint, Mich., to make sheet metal specialties for the automobile trade and also do a general repair work. The organizers are R. S. Gott, A. S. Allen and E. J. Vining.

Dodge Dealers' Requests Number 5,511—Voluntary requests for dealerships numbered 5,511 when a count was made recently by sales manager Arthur I. Philp and his sales force at Dodge Bros., Detroit, Mich., and it was found that from 60 to 90 per cent. of the first year's allotment of cars had been contracted for in most of the sixteen districts.

Ford Employees' Monthly Banquets—Employees of the Ford Motor Co., Oklahoma City, Okla., hold regular monthly banquets at some leading hotel of the city to discuss efficiency matters. The object of these meetings is not only to obtain the greatest efficiency among the employees but it is also for the purpose of working out various plans for the benefit of the Ford owners, especially for those within reach of the local office.

300 Chauffeurs Offer Military Service—At a meeting of the Toronto Chauffeurs' Protection Assn., Toronto, Ont., 300 men offered their services to the military authorities. A letter sent to Major General Lessard from the meeting, stated that of the number thirty were ready to leave at once, men of experience who could handle and do mechanical repairs on every kind of motor vehicle. Several of them had had military training.

Oklahoma City's Safety Plan—The automobile dealers of Oklahoma City, Okla., are discussing plans and co-operating with police authorities in preventing accidents there in preparation for the state fair by conducting a Safety First campaign. The members of the association propose not only to obey the law but to assist the authorities in breaking up speeding and hilarious joy riding. The state plan proposes that pamphlets be printed containing local laws in various parts of the state and be handed out by the gasoline dealers to drivers and tourists.

N. Y. Hupmobile Owners Reunion—A grand reunion of all Hupmobile owners is being planned by Chas. E. Riess & Co., of 1690 Broadway, New York City, on September 9. Invitations have been sent out to all Hupmobile owners in this section to be the guests of Chas. E. Riess & Co. at this reunion, and, so far, over 150 acceptances have been received. All will meet at 2.30 p. m. at 135th street and Riverside Drive, and will then proceed to Coney Island, and dinner will be served on the Upper Deck Banquet Hall, Brighton Beach Casino, Brighton Beach.

Accessories for the Automobilist

Fig. 1—Firestone demountable rims for Fords

FIRESTONE Ford Demountable—A demountable rim, Fig. 1, made specially for Ford cars is now made by the Firestone Tire & Rubber Co., Akron, O. To remove the rim it is only necessary to take off five nuts and therefore it is stated that a tire change can be made in 5 minutes. The rims are furnished complete with wooden wheels so that to install a set it is merely necessary to unbolt the hub flanges, take off the old wheels, put on the new ones with the demountable rims. The price complete is $25.

H-M Light Controller—The glare of the headlights is avoided in the device shown in Fig. 2, by means of frosting the upper part of the headlight glass to a point slightly below the center. Thus no strong, dazzling beams of light pass above the horizontal. The light diffused is not wasted but illuminates the roadway near the car, throwing the rays to both sides and thus aiding the driver when turning corners. It is made by Howard F. Mulcahey, 8 Mt. Vernon street, Providence, R. I.

Automatic Lamps—Increased safety when driving at night is obtained by the use of lamps that are designed to turn with the wheels and thus illuminate the roadway when making turns. The device shown in Fig. 3, consists of a special set of brackets that are clamped to the front of the car, a lever running to the tie rod. The device is made by the Automatic Lamp Control Co., 423 East First street, Dayton, O.

Noll Pneumatic Starter—A pneumatic cranking system, Fig. 4, in which the motor is started by means of the outward movement of a piston, which pulls on a cable and thus turns the motor over several times has just been announced.

A dust and waterproof case, 7 by 7 inches, containing the starter gearing and air compressor, is attached to the engine shaft in front of the radiator, and held in position by means of a bracket which is fastened to the frame.

The air compressor consists of a two-cylinder unit cast in a block and air-cooled, with pistons of cast iron having three snap rings, which are made from a hard alloy. The pistons and yoke form a complete unit and are operated by a specially designed movement which does away with connecting-rods.

All bearing surfaces consist of steel and bronze, one of the best combinations known to mechanics. There are no chains, gears, or sprockets, nothing to break.

The whole is lubricated by the well-known splash system which has proven so efficient in automobile construction.

The starting mechanism is controlled by a specially designed valve which is conveniently attached to the dash. The valve is fitted with patent seats which make leakage impossible. To start the engine, simply push the plunger with the foot and sufficient air is instantly carried to the starter to spin the motor at 600 revolutions per minute, much faster than any starter yet designed. The compressor is started and stopped from the seat, by means of a pedal similar to the ordinary muffler cut-out pedal.

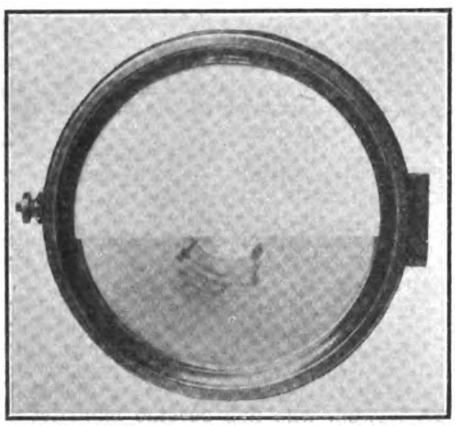

Fig. 2—H-M light controller, a dimming device

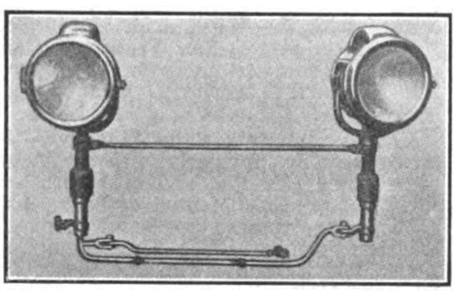

Fig. 3—Automatic lamps to illuminate turns

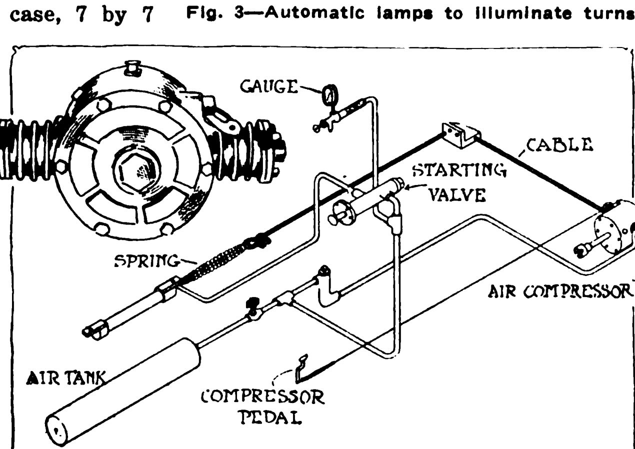

Fig. 4—Noll pneumatic starter. The air compressor that is attached to the front of the car is shown in the upper left and the piping diagram is shown below

The storage tank for compressed air, as well as the starting cylinder, is placed out of the way under the body of the car. Under the pressure gauge on the dash is fastened a specially constructed valve, with hose attachment, by the use of which any tire can be quickly and conveniently inflated, without the back-breaking work demanded by the old-fashioned foot pump. The compressor will inflate a 4 inch by 35 inch tire from complete deflation to 80 pounds in one and a half minutes. For ordinary pumping up of tires, sufficient air can be drawn from the storage tank without starting the compressor at all. It is made by the Currier-Koeth Mfg. Co., Coudersport, Pa.

Burke Tire Valve—Ease of inflation is claimed for the tire valve shown in Fig. 5. At the left it is shown with the valve open and at the right it is closed, being held merely by the pressure in the tire. The valve is provided with a re-

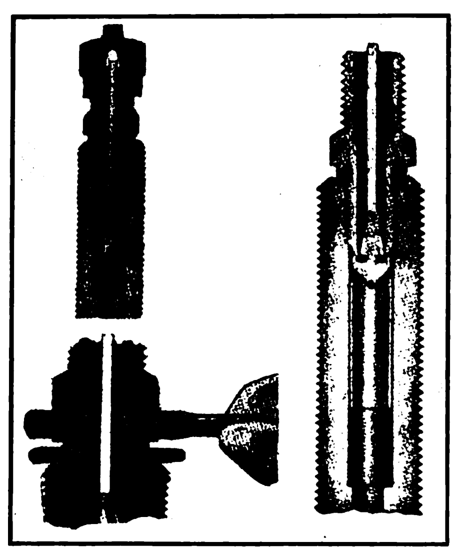

Fig. 5—Burke tire valve. The top left view shows the tire valve open. S is the removable stud, V is the valve proper, and P is a tube that limits the downward movement of the valve. The right view shows the valve closed. At the left, at the bottom is illustrated the method of cutting the gasket G

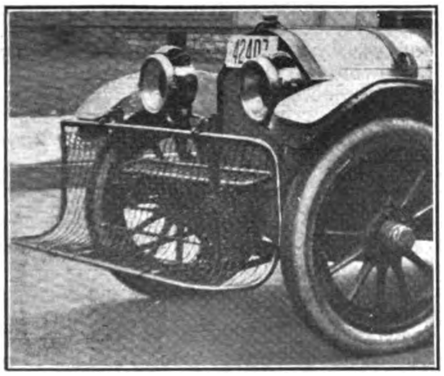

Fig. 6—Linquist automatic fender and brake

versible seat to give increased wear and the tire is deflated by depressing the plunger provided for the purpose. A feature of the device is that the stud is removable so that in case of injury it can easily be replaced.

The gasket between the two parts of the valve is automatically cut and may be made from leather, lead or any other packing material. This is shown at the left, the cutting being accomplished by screwing the two parts together with the gasket material between. The device is made by the Burke Tire Valve Co., 5213 Windsor avenue, Cleveland, O.

Stewart Radiator Meter—The Stewart Radiator Meter, described in THE AUTOMOBILE for August 20, differs from the model previously made in that the water in the radiator is at all times in contact with the thermostatic bar.

Linquist Automatic Fender—To insure the safety of those in the streets against being run over by automobiles and motor trucks, a fender, Fig. 6, has been brought out that automatically lowers itself when an object is struck and at the same time sets the brakes and shuts off the motor. It is made by Wm. A. Linquist, Minneapolis, Minn., and is attachable to any automobile. It takes up little room, extending only 15 inches in front of the car.

Airplex Inner Tires—Immunity against punctures and blowouts is guaranteed by the use of the Airplex inner tube, manufactured by the Airplex Inner Tire Co., St. Louis, Mo. It also protects the inner part of the tube. It consists of an outer cushion which takes the shocks, several layers of fabric to guard against blowouts and an inner tube that withstands the air pressure. The cushion is made of a vulcanized compound and contains no rubber, glue, gycerine, or similar materials. The inner tube is merely to hold the air.

Buob & Scheu Automobile Tops—Seat covers, dust covers and automobile tops for all the standard makes of automobiles are manufactured by Buob & Scheu, Court street and Broadway, Cincinnati, O. The seat and dust covers are waterproof and are made of the best material, it is stated. The arm rests are reinforced with leather. All the necessary hardware is furnished, together with instructions for applying.

Oakbrook Cyclecar Motor—A cyclecar motor, Fig. 7, with bore of 4 inches and stroke of 2.75 inches, and which develops 18 horsepower, it is stated, has been brought out by the Oakbrook Motor Mfg. Co., Reading, Pa. It is an L-head block construction with the valves on the left side and fully inclosed by two cover plates.

Exhaust and intake manifolds are cast separately and the cylinder is a separate casting so that by removing it all the valves and the piston heads are rendered accessible.

This motor car can be furnished either as a separate unit or combined with clutch and gearset.

Ford Valve Grinder—A tool for refacing Ford valves, Fig. 8, is manufactured by the Liberty Tire & Supply Co., 102 Chambers street, New York City. It consists of a suitable guide and cutting tools. The cutting edge can easily be resharpened. The price is $2.

Wireless Dash Light for Fords—H. J. Murphy & Co., Reading, Mass., is making a lamp, supplied with current by a self-contained battery, for attachment to the Ford steering post. In this position, it is stated that the dash is completely illuminated. When a trouble light is needed, it can be instantly detached and used wherever needed. The price is $1.25 complete, and it is finished in black enamel, polished brass and nickel, as desired.

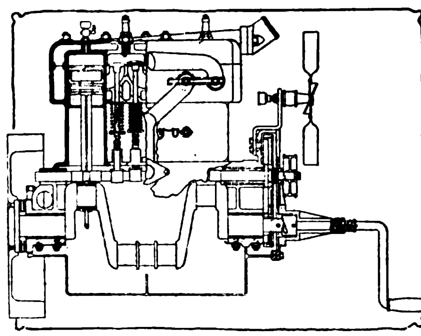

Fig. 7—Oakbrook cyclecar motor

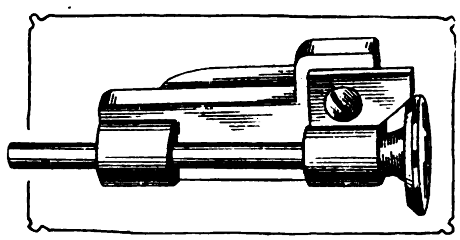

Fig. 8—Ford valve resurfacer or grinder

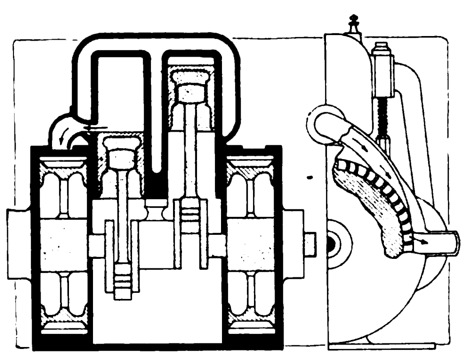

Fig. 9—Standard five-cycle motor

Standard Five-Cycle Engine—A special form of two-cylinder, two-cycle motor, Fig. 9, in which the exhaust gas from the cylinders is made to do work on a turbine type of flywheel, has recently been announced by the American Semi-Turbine Motor Co., 1414 Chouteau avenue, St. Louis, Mo.

It is stated that 30 horsepower at 1,200 revolutions per minute is developed, the bore and stroke being 4 and 5 inches respectively. The two cylinders are cast in a block. At either side of these cylinders there are flywheels, the peripheries of which are provided with vanes against which the exhaust gas is directed.

R. & H. Body—Fig. 10 shows a light car body brought out by the R. & H. Sheet Metal Co., Abington, Mass. The design of this body permits the comfortable and roomy seating of two passengers side by side. Allowance has also been made for the addition of an auxiliary seat in the main body, for a child or other small person. There is ample leg room, even with this extra seat. If wanted, the gasoline tank in the rear can be eliminated, and this space used for a rumble seat, in which case a special tank fitted underneath the cowl is used.

The large 6-inch springs in the seat cushion, and the 5-inch springs in the back cushion afford a measure of comfort seldom obtained in a low priced car. The upholstering material is good quality, black imitation leather.

The door, on the right side, allows for the installation of the popular left side drive. This allows easy access to the sidewalk on the right side of the street, against which most drivers prefer, and in many cases are compelled to stop.

The body is provided with two top irons placed on each side 22 inches apart allowing for easy attachment of the top. The hood is fitted with hinges at the top and finger hooks for lifting, permitting easy inspection of the motor.

Wolfe One-Man Top—Ordinary tops can be remodeled into one-man tops by means of a simple change in the front bows invented by J. Thurston Wolfe, 1843 Calvert street, Washington, D. C. The remodeling is effected by simply attaching the new side arms to the rear bow as shown in Fig. 11. The operation of the top is clearly indicated and therefore it will not be necessary to describe it. The retail price of a set of these bows is $5, and it is stated that any one with a little mechanical skill can put them on. In addition to remodeling, it is intended to sell the sockets to manufacturers for

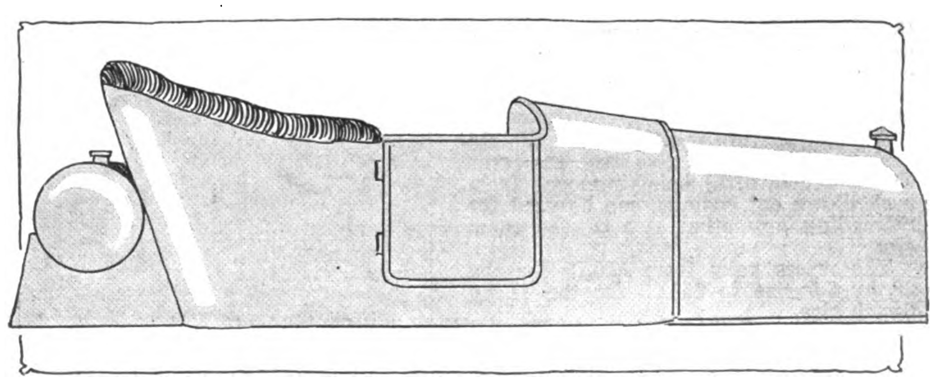

Fig. 10—R. & H. small car body. Also made with rumble seat and cowl tank

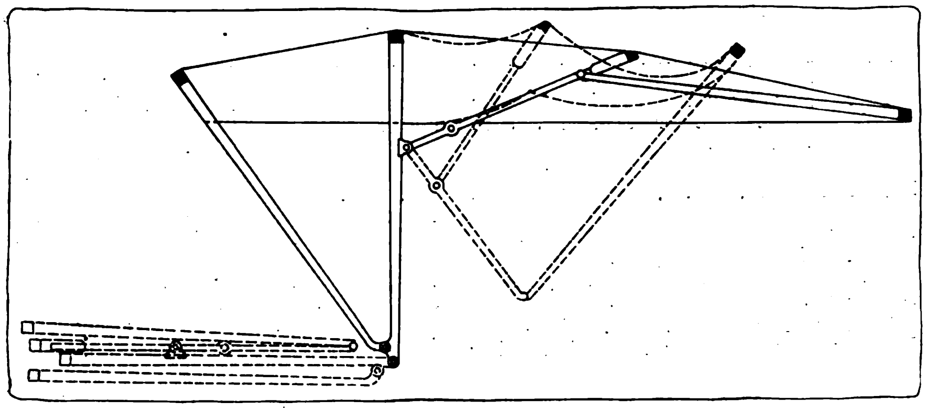

Fig. 11—Wolfe one-man top in three positions, up, half up, and down

new tops. This end of the work is taken care of by the American Distributing Co., Detroit, Mich.

Eight-Day Clock Free—An 8-day standard jewelers' regulator clock is offered to any dealer that will order one case of Non-Fluid oil, providing that he never handled this product before. A case consists of 12, 5-pound cans of K No. 000 Grade Non-Fluid oil at 14 cents per pound and the same amount of K No. 00 Special Grade, also at 14 cents. The former is for greasecups and the latter for gearsets. The clock is 38.5 inches high with a 12-inch dial and runs 8 days with one winding. It is incased in solid oak and will give good service for years, it is stated. The offer is made by the New York & New Jersey Lubricant Co., 165 Broadway, New York City.

Triple Tread Tires—At three-quarters the cost of a new plain tread tire, the Triple Tread Mfg. Co., 1545 Michigan avenue, Chicago, Ill., is offering to retread old casings with its steel studded leather tread, Fig. 12. Three plies of leather are used, the inner one inclosing the outside of the tire completely. A guarantee of at least 3,500 miles is given. Should the casing wear out before the tread, the latter can be transferred at a cost of from $3 to $6, depending on the size of the tire. This charge is to cover the cost of the labor.

The old casing is prepared to receive the tread by the removal of all the old and loose rubber, so that a firm foundation to which to fasten the tread is secured.

The three plies of chrome leather, one of which is brought down the sides of the tire and over the bead, form a tougher and more durable wearing surface than rubber giving better protecttion to the fabric against cuts, punctures, bruises, etc., it is stated.

The steel studs on the tread portion of the tire not only furnish absolutely the best protection against skidding making the use of chains unnecessary, but also protect the leather against being cut by glass, sharp rocks, etc., giving you the the advantage of the highest priced imported steel studded tires.

Another feature is that should the old casing or foundation give way, the same Triple Tread, after being removed from such blown out casings, can be used for retreading any other tire of the same size.

The prices vary from $10.75 for the 28 by 2.5 size to $51.90 for the 41 by 6-inch size.

Perfect Process Vulcanizer—To meet the demand for a medium-priced vulcanizer, simple and safe in operation, the National Cement & Rubber Co., 300

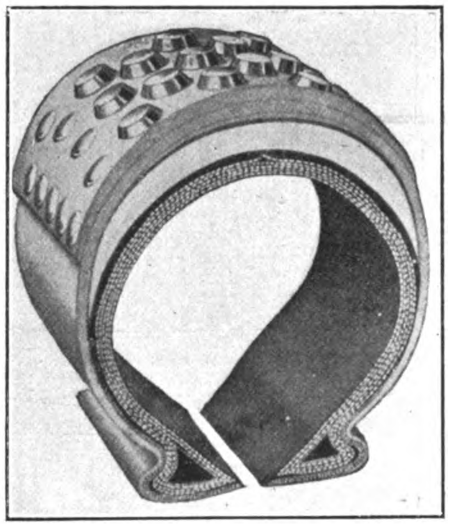

Fig. 12—Triple tread leather tire

South St. Clair street, Toledo, O., has brought out a device, Fig. 13, in which heat is generated by the combustion of gasoline or alcohol. The vulcanizer is placed in an upright position and the fuel poured into the holes in the top. A piece of thin cloth dusted with soapstone is placed over the repair and the vulcanizer is clamped on, as shown. The fuel is then lighted, allowed to burn out and then left to stand for 5 minutes.

Lewis Ideal Tape Reel—Kolesch & Co., New York City, is making a tape reel that is featured by the geared handle which allows greater speed in winding.

It is made of hard aluminum alloy.

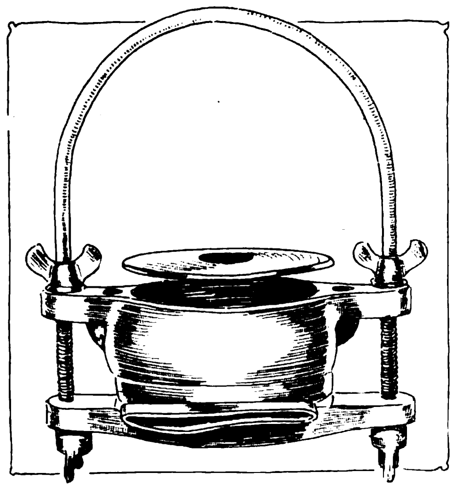

Fig. 13—Perfect Process vulcanizer

Wearing parts of hard steel, handle of bronze, 5 1-2 inches diameter, weight 10 ounces, with high-speed gearing, which will wind up 100 feet of steel tape in about 12 seconds.

Brake for stopping motion of tape at any point and holding it rigid without perceptible effort on the part of the operator. Valuable in winter, as it obviates the necessity of removing gloves.

Complete with 1-4-inch steel tape, 100 feet Eddy steel tape, $17.50 and 100 feet Lufkin steel tape, $15.

West Steel Wheels—Cast steel wheels for motor truck service are manufactured by the West Steel Casting Co., Cleveland, O. These wheels are made according to S. A. E. standards, and are produced in all sizes and styles. The advantages of these wheels are that they will not warp, twist, shrink or loosen—they are cast in one piece, and there are, consequently, no joints to open up, or bolts or rivets to break. Regardless of climate or weather, heat or cold, the shape and form remain the same.

Lefever Small Car Gearsets—Two types of gearsets, Fig. 14, are manufactured for light cars by the Lefever Arms Co., 600 Maltbie street, Syracuse, N. Y. One is a two-speed forward and reverse for cars of 10 to 15 horsepower, the weight of the car not exceeding 1,200 pounds, and the other is a three-speed selective type for cars of 15 to 20 horsepower, the weight of the car not exceeding 1,800 pounds. In both cases ball and roller bearings are used for the mainshafts while the lay shafts are pinned to the casing and the gears are bushed.

Inner Tube Armor—A protection against punctures and blowouts in the form of an inner tube protector is made by the Inner Tube Armor Co., Detroit, Mich. This armor is a liner of cotton fabric and rubber into which metal disks are secured. The armor fits between the casing and the tube and it is claimed no internal cutting is possible.

Apco Starting Crank Holder—A simple starting crank holder for Ford cars is marketed by the Auto Parts Co., Providence, R. I. This holder consists of a piece of spring steel and is applied by removing the spring clip nuts. The slight bend in the spring keeps the crank handle in an upright position thus preventing rattling. It sells for 25 cents.

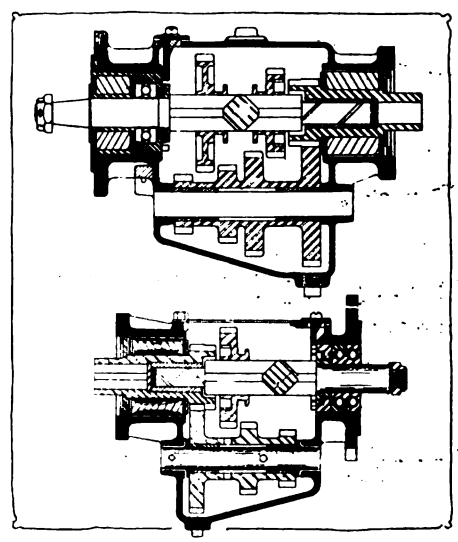

Fig. 14—Lefever small car gearsets. The upper one has three speeds and is for machines up to 20 horsepower, while the lower is a two-speed design for cars of 15 horsepower or under

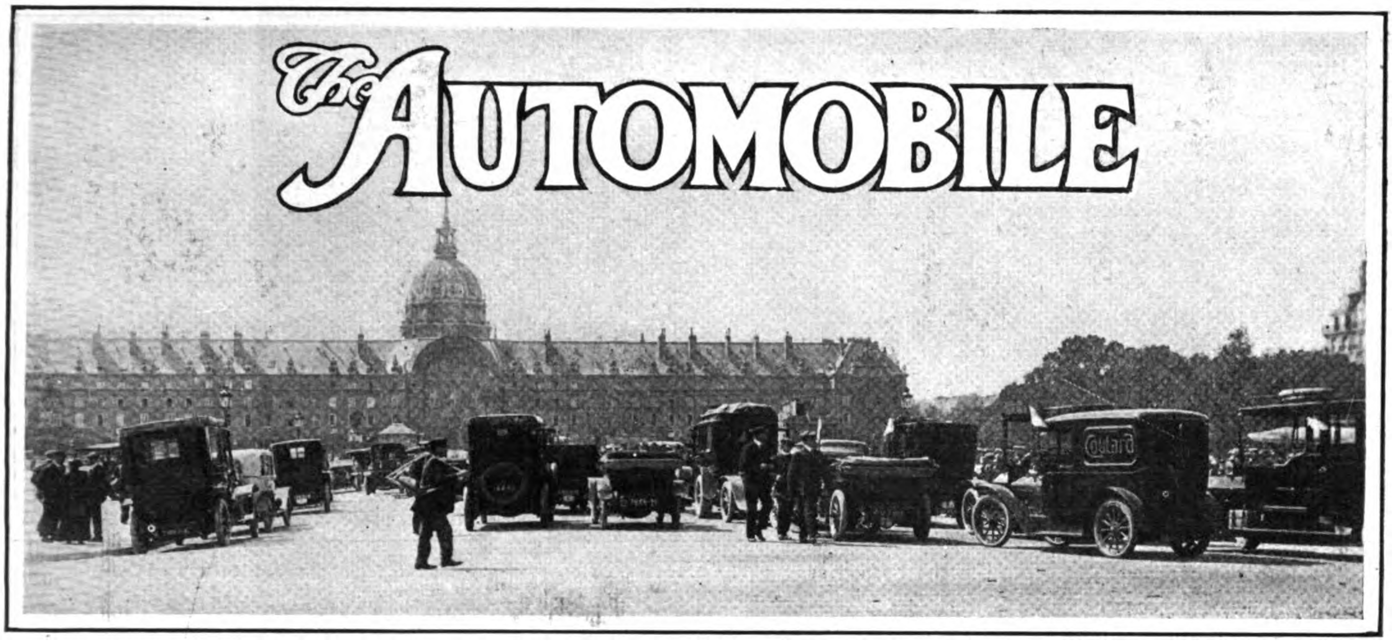
VOL. XXXI NEW YORK—THURSDAY, SEPTEMBER 3, 1914—CHICAGO No. 10



Automobiles gathered on the Esplanade des Invalides in Paris to be requisitioned for service with the troops

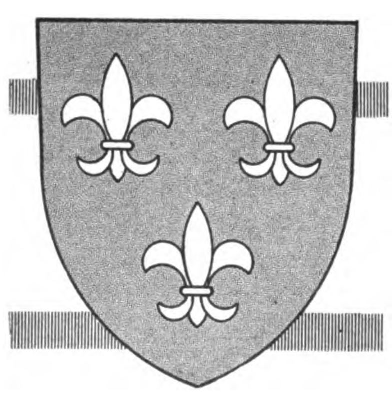
The Call of Mars

100,000 Cars and Trucks Precipitated into Military Service by European Mobilization Orders

By W. F. Bradley

(Special to THE AUTOMOBILE from Paris)

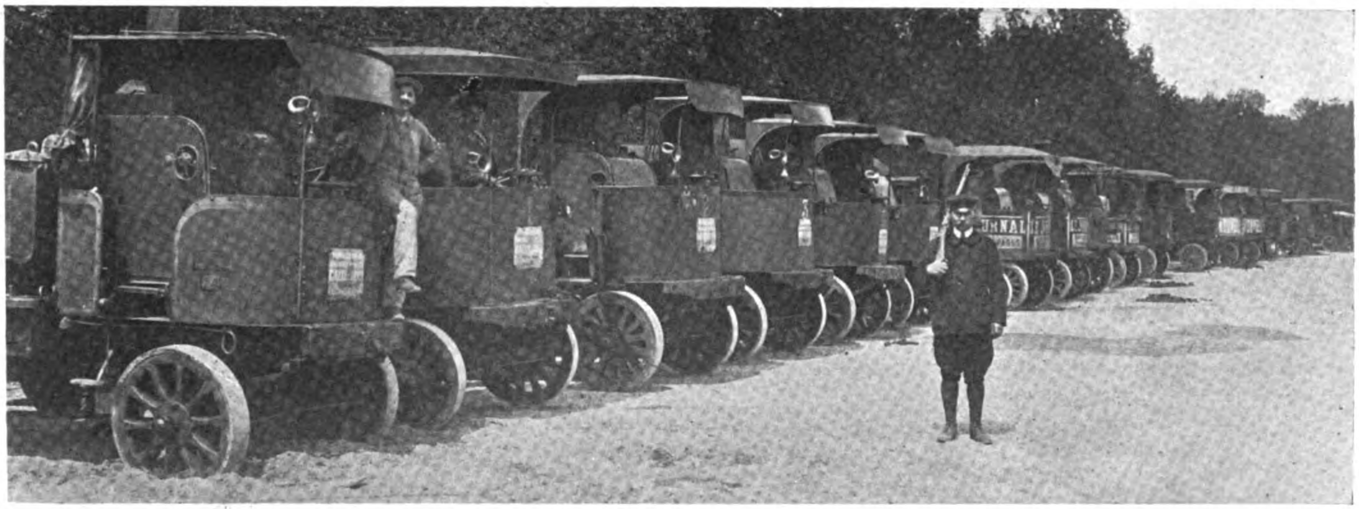
PARIS, Aug. 11—At 4.30 o'clock on the afternoon of August 2 a small, unimportant-looking poster was pasted on the walls of every public building in France announcing a general mobilization. Instantly the life of the nation was transformed. In the great automobile district around Paris machinery was stopped, workmen laid down the tools they were using and within 5 minutes were on their way to the railroad depot. This call to arms automatically shut down the automobile factories. The Delage factory, which normally employs 1,000 men, had but forty left when the army had been satisfied; these forty comprised the least useful units. All the heads of departments, being young men, had gone on the first day. The Darracq factory, which is run under English management, was left with its managers but with no workmen; every able-bodied man under 48 years of age joined the troops.



Exportation of Cars Forbidden

Within an hour of the issuing of the mobilization order another decree went forth forbidding the export of automobiles and parts. Thus, if the factories had been able to work they would not have been able to get rid of their produce. All automobiles on the railroad in course of shipment abroad were put onto sidings and will remain there until the war is over. Most of the cars for England are sent unpacked, while chassis are always exported with no other protection than a layer of grease. These machines are all laid up in railroad depots or on the docks, without any protection whatever and will suffer considerable damage.

There were few exceptions to the closing of the factories. When work could be done for the army the military authorities took over the establishment, or such portion of it as they required, placed the staff under military law and required them to work for the government. All factories producing aeroplane motors came under this heading. The Gnome aeroplane motor works was the first to be militarized; the aeroplane motor section of the Renault works were treated in the same way; Le Rhone, Anzani, Canton-Unne and Clement-Bayard works were militarized. The portion of the De Dion-Bouton factory building trucks and army searchlights continued at work for the army only. The same applied to the Panhard-Levassor factory, to the



Steam tractors commandeered for service in the French army. The transformation of these trucks from a peace to a war footing was marvelously rapid

Schneider works at Creusot, where, in addition to heavy artillery, the Paris motorbuses are produced, and to the Latil factory.

From Peace to War Footing in 10 Minutes

Within 10 minutes of the issuing of the mobilization order, subsidized motor trucks belonging to the big dry goods stores in Paris were being driven away by military reservists. Within an hour of the order going forth there was not a motorbus on the streets of Paris. The Paris General Omnibus Co., which holds a monopoly of this service, has 1,000 buses, of which 900 are constantly in service. As soon as the order was up the drivers continued the journey they were making and then ran for the central depot. Here the buses were transformed by taking out the seats and windows and fitting fine wire gauze screens. The rails for straphangers received meat hooks, and with this transformation, which occupied but a few hours, the vehicles were ready to move to the front. This work was admirably carried out; in most cases the drivers were eligible for military service and remained with their vehicles. The buses were divided into groups of about a dozen, and as all the units in the group are of one type spare parts could be reduced to a minimum. Absolute secrecy is observed regarding military movements, the journalists who publish information likely to be of use to the enemy being liable to court martial, yet it is possible to state that the transformation of the motor buses into meat wagons was carried out with remarkable celerity and that many of these vehicles are at the present time serving with the French troops. They made the journey from Paris to Belgium by road. With the taking over of the Paris omnibuses went the company's reserve supply of fuel and also all their sources of supply. To meet any emergencies a reserve of several hundred thousands of gallons of benzol is maintained in the underground tanks of the company's depots at Paris.

Over 100,000 Cars and Trucks in War

Most careful estimates point to the use of more than 70,000 motor vehicles of all kinds with the French army now advancing into German territory. Fifty thousand touring cars have been called up for service, these being made use of by officers in the various branches of the service, for reconnoitering, for despatch work, for rapid raids into the enemy's country, for flying brigades, and for the Red Cross service. Only a very small number of these cars were originally owned by the army; the immense majority have either been requisitioned or have been brought up by motor reservists, who remain as their drivers, according to a prearranged plan. When the cars are requisitioned their owners are given treasury notes payable after the war, the price being fixed by the authorities. Cars with elegant bodies are generally given over at a loss; officers have no need for fine paint work and elegant finish. Good automobiles with cheap bodies are generally paid a very satisfactory price.

Traveling work shop connected with the aeroplane corps. This is a gasoline truck with a van body containing a dynamo, lathe, drills, band saws, a forge, etc., for repairing aeroplanes

There is still a big demand for trucks. The army has secured 18,000, these comprising all the subsidized models, and many which have been purchased outright since the declaration of war; it has 1,100 motor buses supplied by the Paris General Omnibus Co.; 200 four-wheel-drive tractors, about fifty motor searchlights, and probably 100 various special vehicles, such as water wagons, traveling kitchens, captive balloon cars, etc.

The German army probably has the use of 35,000 automobiles of various types. Belgium, which does not keep up a very big service, has put into use from 6,000 to 8,000 private automobiles and trucks. This gives a total for the three Continental powers of France, Belgium and Germany of more than 100,000 automobiles in war service.

Service Test for Four-Wheel-Drive

Four-wheel-drive tractors, which have been carefully developed during the last 2 years, will come into active service for the first time. The majority of these vehicles have been built by Panhard, other makers being Latil, Renault, and Schneider. These tractors are hauling the 155-millimeter guns, together with their necessary ammunition, and are also being employed for hauling provisions on trailers. If the maneuvers can be taken as any indication of their value, they will render good service in this war. They can travel over any kind of country, for they have been tested over the most difficult land on the German frontier, while their capacity is much greater and their speed much higher than that of any horse vehicles.

Large numbers of automobiles are being used in conjunction with the flying brigade. These machines are a varied class, from light trucks carrying partially dismounted aeroplanes to what are practically ordinary touring cars fitted up to give first aid to disabled flying machines. Aeroplanes work in "escadrilles," each one consisting of seven or eight machines, and having a determined number of attached automobiles. In the important centers a traveling workshop is employed. This is a gasoline automobile with a van body containing a dynamo, a lathe, drills, band saws, a forge, etc., of such a complete nature that practically any repair can be carried out.

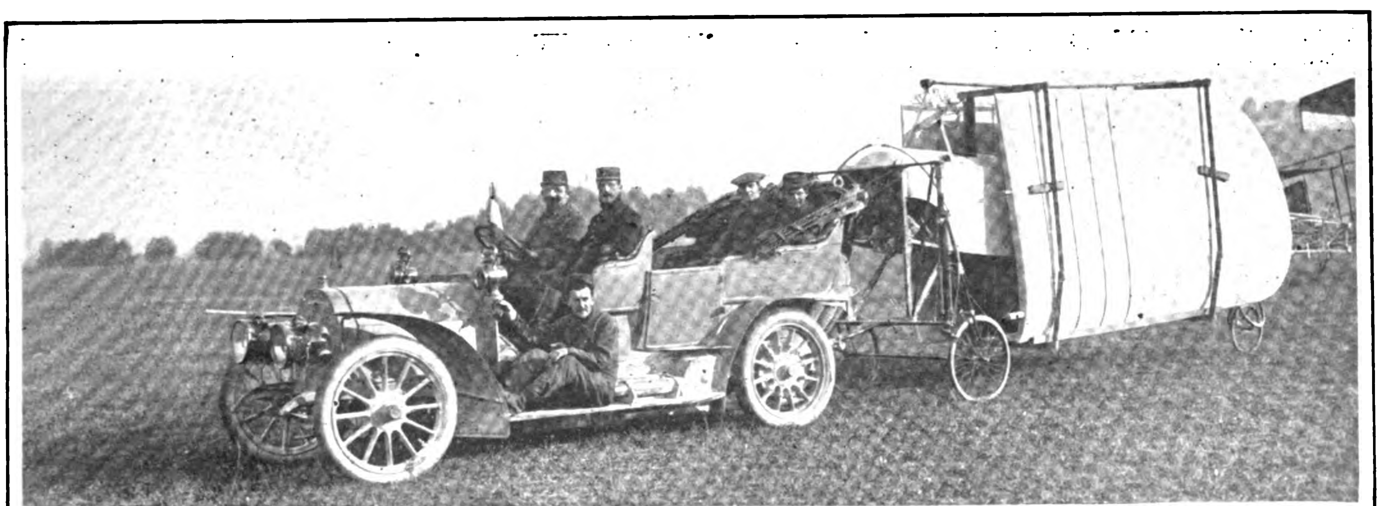
Racing Drivers at Their Posts

All the staff officers make use of private touring cars, the preferred type of machine being a five-passenger fast, open car. Practically all these machines have been taken from private service, the men who are driving them being reservists. In this category are numbers of the leading French race drivers. Georges Boillot was called up just before the declaration of war and with a fast Peugeot was given the task of driving General Joffre, chief of the French army. Victor Rigal, with a similar type of car, was attached to another general. Jules Goux's indicated post was in a fort at Belfort, practically within a stone's throw of German territory. He took up this position immediately he was called, although he might have been incorporated in the aeroplane corps if he had made application. Albert Guyot joined his corps at Orleans, where it is understood that he was given the task of driving an officer. His regiment was immediately ordered to the front and no news is available concerning it. Réne Thomas is in the aeroplane corps and Arthur Duray is said to be with the Belgian army.

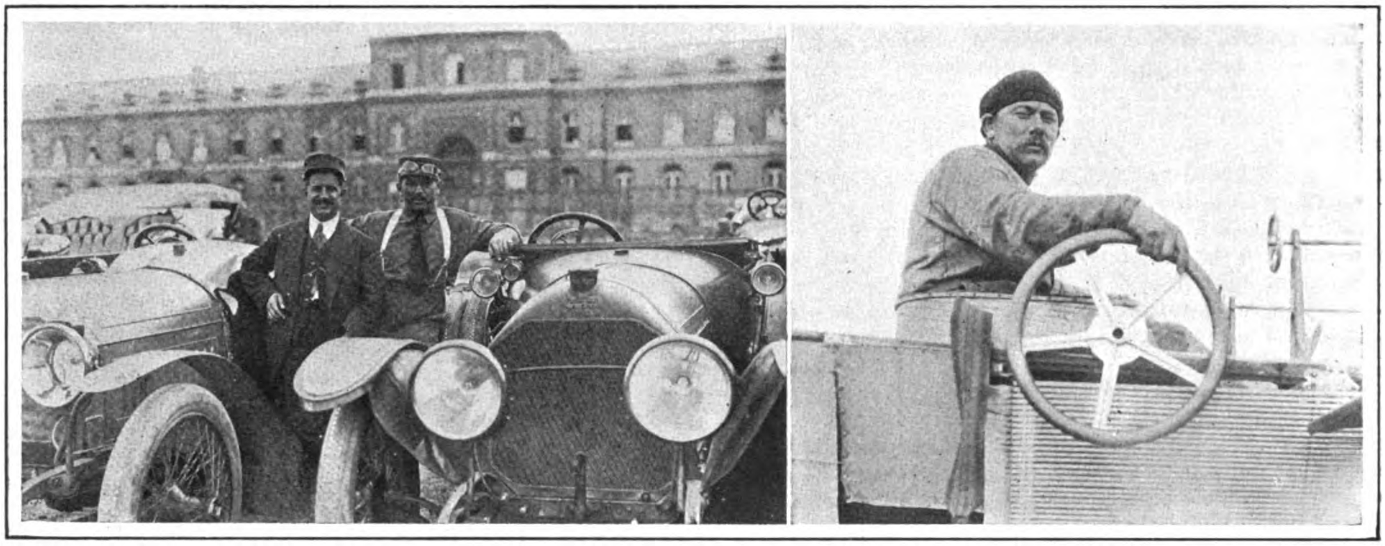
Portable wireless telegraph station used by the French army. This is a motor truck with a special body containing complete wireless outfit

Touring Is Impossible

Automobile touring in France, and indeed throughout the whole of Continental Europe, is an utter impossibility. France has been declared in a state of siege, thus putting the whole of the authority in the hands of the military. It is impossible for any person to use an automobile in Paris unless provided with a permit from the police. To travel outside Paris a special permit must be secured from the War Department. This bears the photograph of the holder and must be shown at every request of the authorities. I have just traveled from Dieppe to Paris, a distance of about 130 miles. On starting out the Dieppe authorities provided me with a pass which had to be presented to the chief of police in every town where I stayed more than 6 hours, and had to be given up for examination when requested. The first request came about 7 miles out of Dieppe. A couple of soldiers carrying rifles with fixed bayonets barred the road and asked for my papers. After they had been carefully examined I was allowed to continue. At the entrance and exit to every village, at the passage over or under every railway, at every bridge over a river, the same close scrutiny took place. At 7.30 o'clock every person had to be off the road, the guards having orders to fire on every person traveling after that hour. My own pass gave me the right to travel to Paris only; before another journey can be made a fresh pass must be secured indicating the route to be followed. This system makes it possible to keep a close control of all cars. As soon as war was declared French subjects who were eligible for military service but were not in the automobile corps had to bring their automobiles for inspection. Many of these machines were commandeered. Others, having no military obligations, had to obtain a special military pass before they could use their cars, and by reason of this application they were brought in contact with the authorities who thus obtained



One of the methods of transporting the aeroplanes over the country by the French army. The aeroplane is compactly folded together and towed by a touring car



Left—Victor Rigal and Georges Boillot as soldiers in the French army. Boillot is driving General Joffre. Rigal is driving an officer of the headquarters staff. Right—René Thomas, winner of the Indianapolis race, who has volunteered for aeroplane service with the French army

the assurance that the cars were in running order, and only consented to issue the pass if assurance was given that the cars could be obtained for army purposes when required.

Escape of American Tourists

American automobilists touring in France were badly hit on the outbreak of the war. Germans and Austrians were given 24 hours to get out of the country or be made prisoners; other foreigners had to leave the country within the same period or comply with stringent police regulations. On the expiration of this period foreigners could only leave the country with a special permit. The only means of escape for American automobilists was by the Channel ports to England. Many a party raced across France with the hope of reaching Dieppe, Havre, Boulogne, or Calais before the expiration of the first day of mobilization. After driving in many cases for 18 to 20 hours without a stop and without a break for food, it was found that the car could not be taken abroad, for at the time the expulsion notice was given an order went into force immediately forbidding the exportation of automobiles. Even if this law had not been in force, the cross-Channel boats were so crowded that it was an utter impossibility to get cars abroad. The outbreak of hostilities coincided with the English Bank Holiday period, when thousands of Britishers invaded the French coast with no thought of war. These people had to get out of the country by midnight of August 2, when all ordinary boat service with England was cut off. Boats which normally carried a thousand passengers took on three times that number; women dropped on the decks and lay where they had dropped.

Abandon Cars on Streets

Motorists, unwilling to believe that the laws were drastic, moved along the coast from Havre to Dieppe, from Dieppe to Boulogne, and from Boulogne to Calais, only to find themselves at midnight on a pier with crowds of casual visitors fighting for a place on a boat and willing to abandon all their baggage if they could get out of the country. In the town of Dieppe alone sixty English and American cars were left behind; along this coast it is estimated that 300 foreign cars were abandoned. Most of the owners had the forethought to place their cars in a reliable garage, from which they could withdraw them after the war, if not requisitioned in the meantime. Others waited until the last minute, then abandoned their cars in the public square. A few, thinking only of their own safety, told the chauffeur to do the best he could, and as soon as the owners had made for the boat, carrying their own baggage, the chauffeur left the car in the street and fought his way abroad. At Dieppe I saw two Packard cars abandoned on the quay side; a French car owned by Americans had also been left behind, the chauffeur not even taking the trouble to stop the motor. I saw this car at 7 o'clock in the evening; when the last boat went out soon after midnight the motor was still running. When the foreigners had departed the French authorities collected these abandoned cars; some have gone into active service with the troops; others can be claimed after the war.

French families were as hard hit as the foreigners. Thousands of motorists were staying on the Normandy and Brittany coasts, 120 to 200 miles from Paris. With the mobilization order the entire railroad service went into the hands of the military; passengers were carried if there was room for them, but no heavy baggage would be handled. As one, two, and sometimes three members of a family had to leave for the front within 24 hours, it was necessary to get back to Paris without a moment's delay. In very many cases open touring cars were decked over, piled up with trunks to a height of 6 feet, and the chauffeur told to make for Paris as quickly as possible. The family followed in a second car, if they possessed one, or trusted to the train service.

Officers Only Motorists in Paris

In other cases a contrary movement took place. Timid persons imagined that safety lay in getting as far away from Paris as possible, and cars were loaded far beyond their capacity to take passengers and their belongings to some distant corner of Brittany. The automobile traffic on the roads during the first day of mobilization was intense. Now that all the troops have been moved toward the east the roads west of Paris are deserted. It is possible to travel a whole day and not meet a dozen cars. Eastward, on the other hand, the movement is intense, but is entirely of a military nature.

Paris traffic is confined to automobiles carrying officers. There is not a single motorbus in the city; three-quarters of the taxicabs have been withdrawn owing to the departure of their drivers for the front. Within the city limits traffic regulations are normal, but no automobile is allowed to go out of the city without a military pass and no car can be on the roads outside Paris later than 7.30 p. m. With very rare exceptions the automobile stores in Paris are closed. The German firms, Continental, Mercedes, Benz, Opel, etc., have taken the precaution to remove all their signs in order to prevent the wreckage of their buildings. There were a few popular outbreaks against Germans on the declaration of war, although no automobile firms were attacked. Since then the authorities have taken all necessary precautions to prevent rioting, for these patriotic outbursts gave an opportunity to the criminal class to work for their own ends. A civil guard has been instituted and big sight-seeing automobiles are maintained at the police headquarters to carry police to the scene of any disturbance which may be reported with the least possible delay.

Many American Cars Held Up

There are numerous American cars held up in France, but they have not been seized. It is possible for their owners to use them, under certain restrictions, but it is not possible for them to take the machines out of the country. There are a few cases of Americans having had their cars taken from them through transgression of the military laws. One of these is James Gordon Bennett, who traveled to Chalons sur Marne, the center of one of the greatest French camps, and was ordered to forfeit his car. The interdiction against touring in certain zones was not put into force without warning, and it is doubtful if there is a single case of a genuine touring party having been detained while seeking to get home.

While the general result has been an abrupt cessation of business, the Packard company appears to be exceptional in having found the war profitable. The Paris branch has not been closed, and, it is declared, will not be shut down so long as it is possible to do any business. With the sudden outbreak of hostilities hundreds of Americans sought to hire cars to travel to the ports. Many had passages booked on steamers but without a car could not get to the shore. Touring parties were willing to pay any fancy price in order to get a car to take them to one of the Channel ports. The entire fleet of Packard touring cars was pressed into service and for several days an uninterrupted service was maintained between Paris and the sea. Among those who got to the sea by the Packard service was the sister of President Wilson.

American Cars May Gain Business

Miss Goode, who is temporarily in charge in the absence of General Manager R. N. Goode in America, states that so far as their branch is concerned the ultimate result of the war may be satisfactory. French people who have had their cars requisitioned are already making inquiries for Packards.

No Molestation of German Car Industries

The Mercedes stores spare-parts department and repair shops at Puteaux, near Paris, have been requisitioned by the army authorities. These buildings are next door to the French artillery factory and have been made use of as an extension to the gun-making works. All the cars which were found in the building have been taken over by the French troops. A portion of this building is also used as barracks for the Paris firemen, now doing service in the suburbs. The Mercedes showrooms in the Champs Elysees have been closed in the usual way, and remain untouched. About a dozen handsome cars ready for delivery are in this store, and are visible from the street, but they have not been taken nor has any damage been done to the building by the populace. Every other automobile store in Paris has been cleared of its stock, and in not a single case is any attempt being made to do business. Much of the French stock has been taken over by the army.

Panhard tractor hauling 155 millimeter siege guns and ammunition wagons

Special army pass given to automobilists, without which it is impossible to travel in a motor car of any description on French roads

In place of cars manufacturers display flags in their windows and a notice is posted to the effect that inquiries should be addressed to the factory. In the whole of the Avenue de la Grande Armée and Champs Elysees district the only store open all day is a big accessory department; a few tire and accessory dealers open for a few hours. Some firms have even taken the precaution of nailing heavy boards across the windows of their showrooms, although the city is so quiet that such a measure is entirely superfluous.

The Continental Tire Co. shut down both its factory and its general offices as soon as mobilization was declared. The precaution was taken to remove the name of the firm from all the buildings, for during the past few years rival firms have conducted a jingo campaign against this firm, maintaining that it was established for the purpose of securing French military secrets. The campaign was never looked upon as more than a doubtful business move, but with the war fever running high precautions had to be taken.

On Belgian Battlefields

I have just been able to make a journey into Belgium, where there is rather more liberty, and to travel a considerable distance by automobile and on foot. Every road is guarded, it being impossible to advance more than 5 or 6 miles without the order being given for papers to be presented. To the east and northeast of Brussels on all the roads leading to the German lines special precautions have been taken against the passage of spies and to prevent the inroads of Germans using automobiles. Heavy farm wagons are placed across the road, one wagon blocking half the road and a second wagon a few yards away obstructing the other half. It is possible to pass between the two wagons, but only at a walking pace. When attacks are feared the space under the wagons is filled up with granite blocks commonly used for paving roads. This makes a strong barricade and at the same time provides interstices for firing.

Standardize Used-Car Prices

Used-Car Central Market Reports of Chicago Automobile Trade Assn. Show Dealers Actual Prices Paid for Cars Without Revealing Business Secrets

Based on Chicago Prices at Present but System Will Be Extended to Other Centers

CHICAGO, ILL., Sept. 1—A "Used-Car Central Market Report," which tells you how much you should allow when taking a used car of any make or any vintage in trade on a new machine, is not a creation of the imagination but an actual fact.

This "Used-Car Central Market Report" has been an actuality for a little over 2 weeks.

The idea of a "Used-Car Central Market Report" was conceived in Chicago by H. M. Allison, President of the Chicago Automobile Trade Assn., on his election to that position last February. The idea was made a reality within the past 6 months by President Allison and his energetic board of directors.

The "Used-Car Central Market Report" is a forty-page book with pages 10 by 7 inches. The book is filled from cover to cover with valuations of used cars. If you are a dealer and a prospect wants to trade in a 1909 Chalmers Model F, 24-horsepower runabout, you can look up your Central Market Report and see that the average allowance for this car in trades has been $325, and further that its value has been appraised by other dealers at $220. So with twenty other Chalmers models any one of which you might have to take in trade; and so with an even hundred other makes of gasoline cars and besides these are fourteen different makes of electrics. You have the value of them all as used cars.

Fig. 1 is a specimen page taken from the first issue of the "Used-Car Central Market Report." It shows the valuation placed on used Packard and other cars. The first column gives the model, the second the year of its manufacture, the third its body type, whether roadster, touring or runabout; this is followed by passenger capacity, number of cylinders, horsepower calculated by A. L. A. M. formulæ and then comes the list price of the car when new.

Actual Prices Paid Are Given

Next you come to the real information, the column headed "Allowance," which means what the dealer selling Packard cars is supposed to allow for the different models. Do not pay too much attention to this column, but pass on to the column marked "As is." This column tells the real story, contains the information you want. "As is" means what these models have actually been sold for, after being taken in in trades. This figure does not mean what one car has sold for but it is the average of perhaps what a dozen used cars of this model have sold for.

After the "As is" column is another headed "Partial overhaul," in which are given the figures these cars have actually sold for after being taken in trade and then partially overhauled.

Then follows another column headed "Rebuilt," which indicates what these used cars have actually brought after the dealer has rebuilt them. These figures are, of course, much higher than those in the two preceding columns, in that the rebuilt used car should bring much more than the partially rebuilt one, or the car that is sold just as it is taken in in the trade deal.

We now come to the last column in Fig. 1 headed "Appraised value." By "Appraised value" is meant a value placed on the car by all of the dealers in Chicago selling other makes of cars listing in the same zone as the Packard. Thus this appraised value would be arrived at by such dealers as Pierce, Locomobile, Peerless, White, Winton and some others. Generally this appraised value comes very close to the actual prices that used cars have brought, it being quite common for the appraised value not to be more than $50 or $75 under the actual selling value of these cars.

Here is another instance from the first issue of the Used-Car Central Market Report of the Chicago Automobile Trade Assn. At the top of the page appears a portion of the Chalmers line, the earlier models being on a preceding page. The prices for Model 10, 1912, show how close the "As is" selling value is to the "Appraised Value." This model was actually sold for $680, and the group of Chicago dealers sell-

Fig. 1—Page taken from the first issue of the Used-Car Central Market Report of the Chicago Automobile Trade Assn. This page shows the valuation of several makes of used cars. Figures record actual purchase and sales prices without betraying any business secrets of the dealers

ing other cars in this class had appraised this model at $700, but $20 higher than it had actually brought during the first 3 months of this year.

Down further in this Chalmers group is a Model 17, 1913 roadster with an allowance by the Chalmers dealer of $900, an actual sale or "As is" value of $850 and an appraised value by rival dealers of $800. These three figures give proof positive of the value of this Used-Car Central Market Report, to the dealer, no matter where he resides. The report is a real guide, not a bit of guess work or approximation.

These values are all based on the first 3 months of this year, and the figures were obtained from Chicago dealers who actually took the different cars in trades and sold them at the figures given, or at other figures that were used in getting the averages of this market report.

Fig. 2 shows the blank form that each member of the Chicago Automobile Trade Assn. is provided with. This slip was actually made out by some dealer; it may have been the Pierce-Arrow dealer, or it may have been Packard, Locomobile, or any other dealer that took this Model 36, 1911 Pierce-Arrow in trade on a new car. After taking it in the Pierce-Arrow was actually sold for $1,150. The dealer who made this sale furnished the information to the dealers' association, but he did not have to sign his name to the blank form, in fact, there is not an indication on the form as to whom it was received from.

The form is mailed to the dealers' association in a double envelop. It is first placed in a plain white envelop and sealed. This envelop, without address or any distinguishing mark, is placed in an envelop furnished by the dealers' association, and on this outer envelop is a number which the trade association has assigned to the dealer. Each dealer has a different number, and one dealer does not know the number of the other. The confidential secretary of the association is the only one who knows the numbers of the various dealers and the only reason that the envelopes are numbered is that he will know what dealers have been assisting in furnishing the information.

These information blanks or sales slips are the real secret of the system. Before this scheme was evolved it was impossible for the dealers to get together. One mistrusted the other. One refused to tell the other what he allowed on a certain used car and what he actually sold it for. But with the secret sales slip scheme many dealers were at once sold to the proposition. They saw that, although giving out the information, they were yet keeping their business secrets, and not throwing open their books to any rival dealer.

The first volume of the Used-Car Central Market Report came from the printer August 5. It contains the information from 753 slips such as is illustrated in Fig. 2. The information was obtained from many Chicago dealers. Each member of the Chicago Automobile Trade Assn. has received a copy of this first report, which is based on actual values in January, February and March of this year. All of the 753 information slips were based on actual sales of used cars in these 3 months.

Not Restricted to Members of the Association

This first volume is not being restricted to members of the Chicago dealers' association, but already books have been sold to dealers in New York, Philadelphia, Boston, Rochester, Buffalo, Detroit, Columbus, New Orleans, St. Louis, Minneapolis, St. Paul, Denver and San Francisco. The Chicago organization is selling a year's service of these market reports for "xx $24." For this amount you get four volumes of the report, one every 3 months. The next volume will go to press on September 5. It will be larger than the first one, and its information will be based solely on sales made during April, May and June. Already over 630 sales slips have been received and it is yet 2 weeks before the date of closing.

When the dealer buys this market service he does not buy

Fig. 2—Blank form with which each member of the Chicago Automobile Trade Assn. is provided. These slips are made out by dealers and record actual business transactions

the books or reports but is only loaned them. He keeps volume one until volume two is published and reaches him, at which time he returns volume one. So on with succeeding volumes, a plan similar to the distribution of telephone directories.

In compiling this Used-Car Central Market Report the Chicago Automobile Trade Assn. divided the entire automobile field into four grand divisions as follows:

Div. 1—Electric automobiles.
Div. 2—Gasoline machines, listing at $1500 and under.
Div. 3—Gasoline machines, listing from $1501 to $3,000.
Div. 4—Gasoline machines, listing at $3,000 and over.

Each division is headed by a chairman and a vice-chairman and in addition to these the membership of the division is every dealer selling cars in this price zone. These dealers as a committee meet and settle the "Appraised value." They also pass on the "As is" sales, and the other department of the work. The committee or division meets perhaps three or four times a quarter year. So all four of the divisions work and pass on the market reports for each quarter.

And why should we not have market reports for used cars? We look into our daily papers for the iron and steel reports, the farmer consults them for the prices of cattle and hogs, the broker seeks them for the lists on cotton or corn. True we would not want a daily used-car report, but we have a quarterly one. In its initial scope the prices are based on Chicago only, but this is temporary. Other zones of prices can be included in succeeding volumes. The Pacific Coast dealers can be brought into line and their lists published under those of the Chicago territory. Added to this can be the New England list, perhaps the Southern list, and lists from any other zones that may be deemed desirable. There is no end to the chain of possibilities. In our grain reports we cite Chicago, Minneapolis, Seattle and other places and so in our used-car reports we can cite different territories.

President Allison of the Chicago trade association in speaking of the possibilities of this used-car market report said:

"This establishes every claim that was made in the Chicago Automobile Trade Assn. when its membership selected committees of appraisement, and emphasizes the value of Chicago as a great bourse in which standardization of used-car values has progressed to a practical point, not only for the members of our association but for dealers in every city in the country, where the clearing house method of establishing proper appraisements of used cars is not readily applied.

"If this great city volume of business in used cars does not make for a central market quotation every bit as reliable as the quotations from a stock exchange or board of trade, then all the laws of supply and demand and market conditions fail to operate."

South America Turns to United States

Long List of Commodities Will Be Supplied by This Country but Reconstruction of Financial Conditions Is Necessary

¶ *The accompanying article is digested from a summary by Charles M. Pepper in the August 27 issue of Iron Age. Mr. Pepper was for 8 years, prior to June, 1913, foreign trade expert of the State Department at Washington. He has toured extensively through South America and has been a close student of trade in all the South American countries.*

THE United States now has the opportunity to supply to the markets of South America commodities which have heretofore been secured from the European belligerents. There will be a deficiency especially in iron and steel products. Germany and Belgium, for the time being, are entirely shut off from the southern Continent and even England, though it may keep the ocean lanes open for its commercial fleet, will find its South American trade dislocated.

While this is the general situation, there is a limitation on the extent to which the United States may profit at once by the deficiency in supplies from Europe. This is the diminished ability of most of the South American countries to buy. The United States, by well-directed effort, may legitimately increase its permanent trade with South America as the result of the war. But too much should not be expected at the outset, because South America during the war period will buy much less abroad than during normal world conditions.

The probability is that the demand for material for harbor and other public improvements, for railroads and for construction enterprises of a public nature will be lessened. The war has paralyzed the ability of the South American countries to borrow money in Europe, and European loans have been the basis of their public improvements and their construction of railroads. Some of these countries were just emerging from commercial crises, due largely to economic causes, and were preparing to refund old loans and secure additional ones.

Brazil was negotiating for a loan of $100,000,000 in London, with some prospect of success. This money cannot now be obtained. Brazil, in fact, has issued an additional volume of paper currency to relieve the stress.

With the Brazilian government restricted in its opportunities for borrowing in order to carry on public improvements, and with private enterprise on a large scale compelled to restrict its activities in railroad building, it will be seen that Brazil is not likely to be a large buyer of certain commodities during the present year. This does not mean any lessening in the value and volume of its permanent market.

Argentina Recovering from Land Speculation

Argentina has been getting on its feet after the monetary crisis which followed the riotous land speculation. Argentine public credit always has been high, and there were some intimations that as conditions improved the effort to float a new government loan, which was abandoned a year ago, might be renewed. The province of Buenos Aires, which was in the market for a railroad loan, was also understood to be on the point of renewing negotiations.

None of these loans can now be floated and some big private enterprises which were dependent on foreign capital will have to be postponed. Argentina, however, is in a position to profit by the war, since the demand for its grain and beef will be increased and higher prices undoubtedly will be obtained. With this source of income assured, Argentina's purchases abroad may not be appreciably lessened on account of the war.

Finances of Chile and Peru

Chile's financial condition has been frequently described as sound, but not sane. That is, the country has abundant resources to meet its financial obligations, but is apt to be reckless in incurring these obligations. Chile will maintain her credit abroad, and will pay all her debts, but she is not likely to get fresh loans with which to carry on public improvements.

Peru was seeking a loan to refund existing loans and meet current obligations when the war broke out. It had no great public improvements under way, and no private construction enterprises of magnitude. Its demand for material therefore may not be materially lessened, but an increase cannot be looked for.

Peru has the gold standard, which helps it in economic and financial crises. The cable reports have stated that the government has authorized the banks to issue checks based on gold to meet the stringency caused by the inability to procure the loan that was sought. Credits may not suffer, but Peru, for the next year, is likely to remain stationary as a buyer of manufactured articles.

The financial and economic situation in these countries is set forth in order that a conservative view may be had of the prospect of the South American market for the United States. American manufacturers and exporters, not familiar with these conditions, might assume that South America would buy next year and this year just as much as it bought last year. If the totals show a falling off in certain lines they might draw misleading conclusions as to the real value of the market and abandon it. This would be a grave mistake.

Having stated some of the drawbacks, it is proper to describe some of the favorable aspects. The purchase of mining machinery is not likely to be altered because mining development goes forward under the most unfavorable conditions. Building and household hardware are not apt to be interfered with, since the demand for these is not affected by international imbroglios. The physical reconstruction of the great city of Buenos Aires will go right on, and the requirements for structural steel, which are so large a factor in its reconstruction, will continue to be large.

Iron and Steel Products—Customs Valuations

The nature of the market of the leading South American countries in detail, as relates to iron and steel products, is exhibited in the customs figures of imports by articles and countries of origin. Unfortunately, however, the statistics are not based on the same system as in the United States. The classifications of the different governments are in no way uniform, each country has its own practice in this regard, and none of them follows classifications similar to those which prevail in the United States.

Most of the South American countries have the system of "aforos," or fixed valuations of different commodities in the customs tariff classifications. Under this practice the value as shown in the manifest given by the exporter to the authorities in the United States may not be the same as the value under the customs classification of the importing country. A typewriter shipped to Argentina may show on the manifest at $50, while the Argentine customs may require it to be valued at $65, or vice versa. The same principle applies to numerous other commodities.

What chiefly concerns the American manufacturer is the commodities which are now imported from European countries, and which may, under the present disturbed conditions, be shifted to the United States if proper effort is made to obtain the trade.

In 1912 Brazil imported $5,368,650 worth of automobiles. Of this amount the United States sent $924,045; Great Britain, $317,873; Germany, $1,526,018; France, $1,470,795 and Belgium, $186,216. The import on motor car accessories amounted to $1,265,430 of which the United States had $110,530; Great Britain, $112,434; Germany, $320,209 and France, $483,508.

The Argentine Republic imported $5,346,149 worth of automobiles. The percentage of this from the United States was but 10.5 while Germany had 15.9 per cent. and France 43.6 per cent. In other words, of the two largest importing countries in the South American field, United States had but 10 per cent. of the business.

Must Buy More from South America

There is a forgotten side to this matter of South American trade. American manufacturers and exporters who are searching for wider markets overlook that some of the countries may also be hunting for expanded markets for their products in the United States. In the present situation it is quite essential that the market for South American products in the United States be enlarged since much of the European market is shut off.

The raw material which may be wanted for the iron and steel and allied industries need in no way be interfered with by the war. The only question is to what extent additional raw products may be absorbed by the industries of the United States.

Manganese, used much in automobile manufacture, exists in Brazil in superabundance, and it can hardly be assumed that the European war interferes with the ability to supply it. In an article on Brazil, published in *The Iron Age* on April 2, the richness of the Brazilian manganese deposits, the facility with which they can be mined and the adequate transportation facilities which now exist were explained. If the iron and steel industry of the United States is embarrassed for lack of Brazilian manganese, it is simply a case of hold-up by the Brazilians.

Big Amazon Rubber Supply

The scare of the automobile industry over a prospective shortage of rubber, because of the war, may or may not be justified, although the supply from the Belgian Congo is undoubtedly in danger, and there may be interference with shipments from the Straits Settlement. But the Amazon has an abundant reserve supply. The hundreds of boats which a few months ago were tied up at Para are doubtless now busy. The jump in the price of Amazon rubber ought to help Brazil through its economic crisis, since the drop in price was one of the prime causes of the trouble.

Chilean copper heretofore has gone largely to England and Germany. The low grade ores from the Braden mine, near Santiago, went to England. Most likely means will be found for absorbing larger quantities of Chilean copper in the United States.

Since the Bethlehem Steel Company's Tofo iron ore mines in Chile were acquired in order to supply the Bethlehem works, there will be none of this traffic to be diverted.

Peruvian copper has been so largely absorbed in the United States that there will not be large additional quantities to be taken by this country, yet there will be some increase.

A final hint may be given on the general subject. Ample data have been gathered by the Department of State and by the Department of Commerce regarding the details of South American trade. The reports of the Consuls to the State Department give much useful information regarding trade conditions. The reports of the Department of Commerce give a vast amount of technical data. What the American manufacturer and exporter should do is to digest this official information carefully and not seek to gulp it down.

United States Banks for South America

NEW YORK CITY, Sept. 1—That American Automobile manufacturers now have the opportunity to repair the damage done to themselves by their own tardiness in seizing the South American opportunity, is the opinion of Ernest E. Ling of the South American Department of the National City Bank.

The application of the National City Bank for the establishment of a branch in Buenos Aires, Argentine Republic and another in Rio de Janeiro, Brazil, is now under consideration by the Federal Reserve Board. Permission will no doubt be granted within a short time for the establishment of these two branches. Mr. Ling, in the course of his work leading up to the establishment of these branches, has closely investigated the financial situation of South America and states that this is but the beginning of wider banking relations between this country and South American nations.

Speaking of the possibilities in this field for the American manufacturer of motor cars, he said, "The automobile manufacturer does not take any risk in seeking the South American business. Of course, he must not expect to find the purchasing power in South America that was there before the war started. Financial conditions in the Southern continent have been much impaired by the war, just as they have been temporarily disarranged in this country. But they are on the eve of a sharp recovery.

"Financial conditions in South America have been bad for the past 7 years due to the wild land speculation engaged in throughout all the important countries. Improvement, however, with the establishment of better commercial relations with the United States, is sure to come and the establishment of better banking connections between New York and the Southern capitals is a big step in the right direction.

"While the purchasing power of South America may not be as high as it was last year nor as high as it will be in a year or two from now, still it will pay the automobile manufacturer to go after this business. He will not be taking any undue amount of risk in doing this, and he now has an opportunity to overcome the effects of his tardiness in securing the South American trade. He has been asleep while the German and French factories have been busy.

"What the South Americans would like to see most is not a single shipment of cars on the orders secured by traveling representatives of the factory, but permanent branches through which dealings could be carried on in a permanent manner and by means of which the owners would be assured of competent service in repairs and parts."

Australasian Trade Has Been Growing

War May Spoil Market—At Outbreak Country Was Very Prosperous—Australia Considering a Tariff

Passing a bullock train near Sydney, New South Wales

OUR trade with Australasia, which has been rapidly increasing during the past year or two, will probably fall off, on account of the European war. Facts, gathered just before the outbreak of hostilities, show that, while there are peculiar conditions to be met in this part of the world, many American companies had built up a flourishing trade. The country is in a prosperous condition. The wealth of the inhabitants is in the land and the majority of these people can afford cars but the war may prevent buying.

One feature that is worthy of serious attention is the possibility of prohibitive tariffs against imported automobiles. The question of putting a high tax on automobile bodies in order to stimulate the home manufacturers of these commodities is now being considered and extension of this policy would be disastrous to the import trade in motor cars.

"The demand for American automobiles in Australasia is increasing," according to Mr. Henry Kennady, managing director of the Studebaker Corp., of Australasia, Ltd, with headquarters in Sydney, New South Wales, and at the present time on a trip to Detroit—in an interview just before the war.

"Competition with European cars is exceedingly strong and the American automobile agent and representative has no easy task in overcoming this competition. It means everlasting hard work and using of strong, convincing arguments to show the good points of the American motor car. All leading automobiles made in Europe are represented in Australia and they were well known there long before American manufacturers of automobiles had representatives or agents in Australasia. Among the European cars most to be found are the Benz, De Dion-Bouton, Darracq and Brasier.

"The Australians want an automobile with right-hand drive, because in Australia they drive on the left side of the road and not on the right. Cars must have a high clearance, like American cars, because the road conditions are quite similar to those in the United States. There are many sections in the country where there are only sandy roads, others hilly and a great many with rocks. The Australian also wants a car with a four-speed gearset, prefers cars painted gray and having a low appearance, and with a khaki top.

Half of Business in Five Cities

"The bulk of the automobile business, at least 50 per cent., is transacted in five cities. These are the capitals of the states in which they are located: Sydney in New South Wales; Melbourne in Victoria; Adelaide in South Australia; Brisbane in Queensland, and Perth in Western Australia.

"People in the country who want to buy a car go to the big dealers established in those cities instead of going to the nearest located dealer of their city or nearby town. The retail business is conducted on time while the wholesale trade is on a cash basis.

"The farmers buy automobiles and some own several cars and all are as enthusiastic as the city people in reference to automobile matters. There is no prejudice against the automobile and the lawmakers do not spend much of their time in proposing measures which would injure the development of the motor car business. The same refers to the authorities who are well disposed towards the motorists. The taxes are reasonable and the only thing which is now very much needed is the improvement of the roads.

"Were it not for the very poor and bad roads there would be many more autombiles sold, but, outside of the city limits of the five big cities and a few smaller ones, the highways are about the worst that could be found.

"There are not many trucks and commercial vehicles and the demand for them is very limited. The cause of this is the fact that the concerns which could really use such vehicles to advantage think that owing to the bad roads, the motor cars would soon give out, and it would cost more to operate them than horses and wagons.

"The conditions of the automobile business in New Zealand are about the same as in Australia, with the difference that the business is not restricted to only a small number of big cities, but is spread over the whole country."

During the first six months of the present year motorcycles, motor car bodies, and motor car chassis to the value of £377,177 were imported into New South Wales. This exceeds the value of the motor imports for the corresponding period of last year by no less than £98,000, equivalent to an increase of 35 per cent.

These figures are significant in that the value of the motor imports for the first six months of last year showed a decrease of 10 per cent. when compared with the imports for the first half of the year 1912, and in consequence of the rapid gain in public favor of the inexpensive American runabout to the detriment, it is said, of the high-class European business, it was generally expected that the values this year would show a further falling off, despite the large numerical increase of cars on the roads of the State. This, however, is shown not to be the case. The United Kingdom still has a lead over all other manufacturing countries in the total value of motor car chassis, bodies, and motorcycles imported, but the United States of America delivered, roughly, £17,000 worth of motor car chassis and bodies more than the United Kingdom. America holds this position partly owing to her manufacturers supplying few other than completely equipped cars, whereas the British makers, as well as the majority of the Continental factories, export their cars in chassis form, leaving the building of the bodies to the Australian dealers, who thereby save a considerable amount in duty.

In the gross imports, including motor cycles, motor car bodies, and motor car chassis, Great Britain comes first with goods valued at £134,042, the United States second with £123,028, Canada third with £44,861, Germany fourth with £27,000, France fifth with £21,439, and Italy sixth with £18,520.

France is the only manufacturing country which has lost ground in her exports to the State during this period. Her motor cycle trade has fallen from £107 to nothing, motor car body trade from £2,081 to £618, and motor chassis trade from £23,362 to £20,821.

In the wheat and wool seasons, all the harbors and ports are congested with ships waiting for the big cargoes that are offering. According to a large dealer in Sydney, writing under date of July 30, "Should anything ever happen that the foreign markets become affected through any cause, such as the present scare through the Austrian-Servian war, conditions in Australia will become bad, and the reverse to general prosperity will immediately set in. As soon as the products of the land cease to find a foreign market, the city trade comes in a very bad way very rapidly. It merely requires a sign of a drought, and depression sets in immediately. Australia has been famous for droughts in the past, and everybody is nervous of the word.

"Everybody on the land who has a small holding, is making money, and this is due to the rapid rise in prices in land products. Foreign buyers all over the world are increasing in number each year, and the last couple of years or so we have had representatives of Libby's, Armour's, and Swift's, well-known in Chicago, giving good prices for sheep and cattle, and there has recently been started a direct service from Australia to American ports with frozen products for these three well-known firms.

"With such rapid rise in prices, money has been flowing very freely into the whole of this country, and the bulk of the money has gone to the man on the land, and he is to-day the most prominent automobile buyer there is in Australia. Every house in the city is advertising in such a way as to draw the attention of the farmer.

May Adopt Tariff on Bodies

"The adoption of a tariff will probably affect the trade in America a great deal. There is a royal Commission sitting in the various States taking evidence on the tariff question and there is every probability that there will be an almost prohibitive tariff imposed upon motor car bodies. The motor car body building business in this country is in a bad way. Practically no companies have any capital behind them and consequently manufacturing is carried on by what one might call amateur methods. Machine work and stamps, etc., are entirely unknown.

"However, as I have said the tariff is likely to be raised to such an extent that bodies on the cars will land here at a great expense. Strange to say the body builders are asking for very high protection against bodies fitted to the cheap American cars; that is their phrase, and as the labor market dominates a great deal in politics in this country, there is every indication of substantial increases.

"Two American small cars arc now in Australia and this line of vehicle is going to catch on and thoroughly drown the British cycle car in the matter of numbers of sales. The British car, however, will still live, on account of its superior finish and workmanship, but of course the price is more than double.

"The greatest motoring centers in Australia are New South Wales, Victoria, South Australia and Queensland, in the order named. Western Australia is only a small populated place and is principally a mining center and the interests in the mines are generally owned in the Eastern part of the continent, hence the profits and the wealthy people are living in the East.

"Of the remaining States there is an Island State called Tasmania, about 90 miles in diameter. This little island is very rich in soil, and the whole of Australia is practically fed with fruits and vegetables from it, and a tremendous fruit export, chiefly apples, is carried on each year. Tasmanian apples are well known in the English markets.

"The wealth of the country is in the land. Australia, by reason of its small population, is not a large manufacturing country, although several prominent works are now being started, including two large steel and iron factories. These have just lately been erected, and give promise of a very large industry.

"The main thing Australia depends upon is wheat and wool. New South Wales is a sheep and wool country, and the Southern portion of New South Wales, and the whole of Victoria and South Australia are practically a wheat belt. Without exaggeration, some of the largest farms in the world are to be found in South Australia. There is also a very large wool export both from South Australia and Victoria.

"Queensland is mostly a cattle country, and practically the whole of the beef for Australia comes from Queensland. Along the Queensland coast in prominent towns, are nothing else but huge meat preserving depots, carried out on the same lines as some of the American ones, but of course much smaller. As a matter of fact, there is a lot of American capital invested in these meat works.

"Each of the five States of Australia has great mineral wealth. Queensland is notable for the Great Mount Morgan Copper Mines, also many gold mines, whilst New South Wales is one of the largest coal fields in the world. It is only second to the great Welsh Coal Fields in Great Britain.

"Victoria is a gold-mining country in one of the first ranks, and so is Western Australia.

"South Australia is very rich in copper. In fact a large portion of the world's supplies comes from Moonta, Kadina and Wallaroo Mines.

"Broken Hill, which commercially belongs to South Australia, but is in the State of New South Wales, is famous for silver and lead mines. The Broken Hill Proprietary claim that they have a greater output of lead than any other mine.

"Thus it is readily seen that with the big production of mineral wealth, also of wool and wheat Australia has to look to foreign markets, and every boat that comes to Australia with general cargo, generally goes away with a full cargo of wool and frozen products, and bullion."

Russia—A Trade Opportunity

Prejudice Against American Cars Because of Ugly Appearance of Early Types and Rough Finish—Few Attempts Have Been Made to Gain Russian Market—Part III

By the Late E. P. Batzell

¶EDITOR'S NOTE.—*This article was prepared some time ago by Mr. Batzell and so must be taken as a description of conditions in Russia at the outbreak of the great European war.* THE AUTOMOBILE *is indebted for the illustrations to The Autocar and to the White Company.*

CONCERNING the standing of American cars on the Russian market at the present, it is satisfactory, no make having acquired any particular territory. Even the Ford, which is most advanced in this respect, cannot show any gain over the European cars, as was explained in the preceding installments. In this connection it is interesting that the public reveals a certain well-pronounced prejudice against the American machine, as the writer was able to ascertain by investigation of different parts in Russia. No American car has definitely conquered public antipathy in any part of that country, the Ford selling chiefly through its comparatively low price to the more undiscriminating parties. This situation is not characteristic with other American goods, which are generally well liked there, but one has a hard problem on hand when trying to convince the public as to the merits of an American automobile. Leaving aside the question of price, there is no belief in the even quality and better adaptability to Russian conditions of the American car in comparison with the European, when the matter deals with a car costing about $2,000. Those few who are more or less familiar with automobiles in a technical way and who understand their production are inclined to give due credit to the American machine and the way it is made, reproaching it merely as to its looks.

Early Cars' Appearance Created Prejudice

The American machines indeed possessed a particular appearance until very recently, differing from the general European style, the latter being the more attractive to the tastes of the Russians. Their criticism followed naturally. It is gratifying, however, for the American foreign trade, that the latest and most up-to-date American car creations have successfully overcome this point, by adopting the European style of body, fenders, etc. These will find the door into the Russian market somewhat more open than before, inasmuch as they will meet the taste of the public.

The prejudice existing against the American machines is not only because of their exterior appearance. The much less careful work noticeable on the average product of American factories building cars in large quantities certainly leads the observer to believe that the working and vital parts of the machine are apt to be made equally roughly and with a lack of accuracy essential for their proper functioning. This point of view is further increased by the amateur conception of American production methods in general. A talking point of immense scope thus is available to the dealers in European cars which are smoother, better looking and better balanced in their exterior appearance. The American car and its early efforts to come into the Russian market are both much to blame for this unfavorable reputation, from which it is hard to divert the public now, even by offering them products of much superior quality. Apparently the better American car building firms have not tried to work the various export markets until recently, because their output of cars could be easily distributed and absorbed in the home market without the additional trouble and expense connected with the endeavor of establishing a foreign trade, particularly in a country as little known and as little attractive from the industrial point of view as Russia is. To producers of popular-priced machines in very large quantities, for whom it was impossible to place all their cars in the home market, the export trade offered a good prospect for profits, and thus those cars came into Europe and into Russia. Some introduced their cars through independent agents, other who were building automobiles parallel with other articles already used in Russia, could use the services of the latter representatives. Although the imported machines could have been quite successful in the United

States, with their first appearance repulsed the public, who were used to seeing something much better looking and more carefully made. Nevertheless, the price at which the imported machines were offered made many sales, the buyers trusting that there was good stuff behind the rough exterior appearance. It is to be regretted that only very few of these purchasers have not been disappointed after short period of ownership. In some cases the machine bought was of poor quality, of a make which could not have any standing for its product at home. In other instances the cheap American machine offered at $1,500 to $1,800 in Russia was expected by its owner to do as well as the $3,000 to $4,000 European car of the same weight and power. Nobody will deny, that there can be no comparison between the above two types, because in such an American machine one does not find the materials and workmanship to be found in the European car of double the price. Therefore, the inexperienced owner trying to maintain a pace of 30 miles per hour in his cheap American machine upon the country and cobblestone roads of Russia within a few months' time reduces his car to an annoying rattlebox, at the very best. One can imagine how this owner would feel about his purchase, and, as rumors travel far and wide, the public got to base its dislike on something more concrete than mere appearance. Even now one looks on the American machine generally as a cheap product, not wanted by anybody of a certain standing, just the same as there is a different class of trade for one store than there is for another.

Some reputable American concerns are doing hard work through their agents to establish good reputations for their cars in the public opinion, and they start to have some not unfavorable returns. They sell cars and sell more from year to year, but even the sale of Fords does not approach in number the sale of European high-priced machines, as was mentioned before. The Ford car is finding much use in its inclosed body type for city driving with those who don't care to spend much on an inclosed car for winter only, having a more expensive touring car for the summer.

Large Capital Required by Agents

European automobile factories doing big business in Russia almost always have their own branch houses there. This should be preferable for a large scope of business, because many agents, especially those representing German cars, get their stock of the latter practically without deposit, just on commission. When the agent has to pay considerable deposits to the factory for cars received or shipped, he is obliged to possess a large working capital, particularly so if he works in connection with sub-agents. These are generally small parties, who even cannot always devote the whole of their time to the selling of the cars they are representing, and they seldom deposit much of an amount with the main agent who furnishes them cars, until the latter are sold. This method ties up the capital of the main agent if he has to pay for his cars to the factory on their delivery, at the same time being able to get his money back only after the cars are sold to customers. One must keep in mind, that business goes much slower in Russia than here, and whereas an automobile agent here can make a yearly business of tenfold and more than his working capital amounts to by changing it around rapidly, there he must have a much greater proportion of working capital to the yearly business transacted, because it is impossible to turn one's capital around rapidly enough. Only the richest agencies start on a big scale there, the majority growing up gradually, increasing their facilities and their scope of business with their ability to get better credit at the factory which they represent. The Russian agent is said to be a little better off than elsewhere in the matter of storage space for cars arrived in shipment. In many instances he finds it more profitable to let the cars be kept in the warehouses of the carrier, until they are needed, paying a nominal charge for that, than to rent a suitable storage house for them. This method also offers other conveniences.

Garages and Repair Shops Have Difficulties

From the standpoint of service, those buying better and higher-priced machines actually get good satisfaction. As a general rule the agencies and branch houses have their own garages and repair shops, or, if the business is small, they rent space in a garage and shop for their customers' needs. All dealers carry repair parts in stock now and it does not take much time to make a repair or replacement there. Some have shops equipped to make parts to order, serving the owners of old automobiles and those whose cars have no direct representative in the country. Occasionally the agency or branch house does not run its own service garage and repair shop, but contracts with a party well equipped to do this kind of work, where it directs its customers. This latter method is particularly profitable for a small business of late, when, with the use of electricity in cars and some other improvements, they require occasionally the service of expert specialists, which the small business could not afford to hire directly for their exclusive benefit. On the other hand large garages and repair establishments with a large trade of great variety can afford and have such specialists. The arrangement shows some benefit to the owners also, who can deal with the garage, etc., through their agent.

The repair work in branches and private establishments generally is done well, because the reputation of the enter-

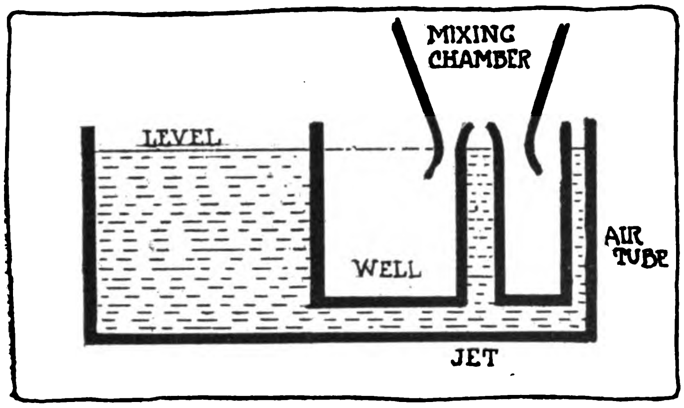

Fig. 1—Diagram showing principle of flooded jet

The Rostrum

Explanation of Flooded Jet

EDITOR THE AUTOMOBILE:—Will you please explain what is meant by the flooded jet and illustrate the working principle upon which it is based.

Atlanta, Ga. H. CORWELL.

—As the name implies, this is a jet placed below the level, Fig. 1, and through which the gasoline tends to flow constantly on account of the difference in levels. In order to eliminate a mechanical means of closing the jet when the motor is not running it is placed at the bottom of a well, the sides of which are slightly higher than the level of the gasoline. When the motor is at rest the well fills up to the level of the gasoline, completely drowning the jet and preventing it from giving off any more gasoline. An air passageway in communication, at one end with the base of the well, and at the other extremity, with the exterior allows air to pass in and carry with it the gasoline given off by the jet.

Well Filled When Motor Is Stationary

When the motor is stationary the well and the passageway are filled up to the corresponding height of the level in the float chamber. As soon as the motor is started a depression is produced in the mixing chamber or throat. The gasoline tends to rise in the well to a height equivalent to this depression. But, as the sides of the well are scarcely any higher than the level, the gasoline leaks or dribbles along the walls of the well and is carried along, at any rate in part, by the lapping effect. At this moment the carburetion is very insufficient because the gasoline that trickles along the outside walls of the well is not vigorously vaporized and carried in by the current of air. The flow of gasoline is then that of an ordinary jet acted upon by the depression which obtains at the orifice of the well. According to the degree that this depression increases the level decreases in the air passageway and as soon as the depression is equal to the column of gasoline which is flooding the jet, the air will enter the passageway, carrying with it the gasoline that remains in the well, and leaving the extremity of the latter, passing into the mixing chamber.

Depression Becomes Double

At that moment there is a discontinuance of the procedure, as the depression which exists in the mixing chamber makes itself felt in the base of the well as soon as it is empty. The moment the gasoline is taken from the well the depression, which was as great as the height of the flooding, suddenly becomes double. Further the flooded jet does not come into operation until the depression is sufficient to expel the gasoline from the well; but at that moment it is stirred up, leaving the orifice of the well, and then intermingles with the air. The gasoline thus expelled, which operation is not the least of the advantages of the flooded jet, makes an effective combination, producing a great mixture even with small depressions, which is equivalent to slow-speed running for picking up and running on a grade.

Determine Acidity with Hydrometer

Editor THE AUTOMOBILE:—1—Is there an instrument made for determining the acidity of a storage battery solution? I do not mean a hydrometer, but something to show when the battery contains the proper amount of acid and water. If there is such an instrument, please describe it and tell the principle on which it works.

2—I have been told that it is a good idea to pour out the battery solution occasionally and replace it with new solution. Do you recommend this?

3—A short time ago I had a pound in my engine which disappeared after having the carbon burned out with oxygen. After running only about 150 miles the pound is beginning to come back.

East Canaan, Conn. D. C. CANFIELD.

—1—There is no simple method of determining the acidity of the electrolyte other than by the specific gravity method which involves the use of the hydrometer.

The acidity could be determined by one of the methods used in quantitative analysis, and while this could be worked out so as to be simply done, it would not be as simple and as convenient as the hydrometer method.

With 100 per cent. sulphuric acid the specific gravity is 1.94, which means that it is 1.89 times as heavy as water at 60 degrees Fahrenheit. It is evident that if water is added to the acid the specific gravity of the solution will decrease, and in exact proportion to the amount of water added, until with no acid the gravity is unity. In other words, the specific gravity of the solution indicates the amount of acid or the acidity.

Possibly you have misunderstood the purpose of the hydrometer. It is not to determine the gravity itself, because that is of no intrinsic importance, but to find out the acidity—the proportion of acid to water. Fig. 2 gives a curve showing the percentage of sulphuric acid in water, for varying densities, at 60 degrees Fahrenheit.

2—This should never be done. You should, however, observe the following directions. Distilled water should be added weekly in summer and twice a month in winter, to replace that lost by evaporation. Add enough water to submerge the tops of the plates by about ½ inch. If distilled water is not available use rain water or melted ice.

If the tops of the plates are uncovered the effective area of the battery cell is reduced. While if too much water is added the cells will slop over.

Never add acid unless you know that some has been spilled out. Every few weeks the gravity of the cell should be determined by means of a hydrometer. The syringe type is most convenient for this purpose and can be bought anywhere.

The electrolyte of a fully charged cell should, when first put into service, have a specific gravity of about 1.280, and although with age this gravity will change somewhat, the battery will continue to give good service if the solution is between the limits of 1.250 and 1.300. If, on testing the electrolyte, it is found to be above 1.280, with the battery charged, a small amount of the solution should be removed and distilled water added. Make sure, however, that the solution is not allowed to drop more than ½ inch above the tops of the plates.

Low gravity in a battery is usually caused by acid being combined in the plates through lack of charge, although if a battery is upset and acid spilled or a jar is broken and acid leaks out, no amount of charging will restore the gravity.

Battery Should Be Charged First

Before attempting to raise the gravity of any cell by adding acid always charge the battery until sure that a maximum gravity has been reached, or, in other words, until no acid remains combined in the plates. For example, if the electrolyte in a cell should be adjusted to 1.275 when 50 points of acid remained in the plates, the gravity would come up to 1.325 if the cell were afterward charged to the maximum.

To adjust the battery to its proper value, 1.280, first bring the battery to its true maximum, which can only be assured by charging until no further rise in gravity is noted during a period of at least 24 hours of continuous charging at one-half the normal finishing rate. Then if the gravity is too high remove the electrolyte down to the tops of the plates and replace with water or 1.300 electrolyte as required.

3—The knock is probably due to some other cause than carbon, if the removal was complete. But without more details concerning the sound made it is impossible to say exactly where the trouble is. Lack of oil or improper cooling would cause a knock, but as you are using a large amount of oil it hardly can be the former. See that the water is circulating properly and that the fan belt is tight.

Next see that the compression is good in all the cylinders and that the spark lever is working properly. It is possible that some part of the linkage is loose, so that when the lever is moved the spark is not retarded. If the carbureter is not in good adjustment it should be attended to, because a poor mixture will cause a knock.

Possibly there is play in one of the motor bearings. If the knock is more perceptible when the motor is being slowed down, it is likely that this is the case.

Gasoline Consumption Low

Editor THE AUTOMOBILE:—1—I would like to know whether I could cut down my gasoline bill by putting on a new carbureter, as the one I now have gives me only 8 miles per gallon. My machine is a 1912 Palmer-Singer, having a carbureter of the three-jet type of the same make. The motor is the T-head type. This car weighs 5,300 pounds. Is the carbureter O. K.?

2—If the carbureter is O. K. what could I gain in miles by fitting another magneto to fire over the exhaust valves?

3—Where could I buy new caps for plugs for this car?

Swedesboro, N. J. T. H. BOLTON.

—1—This car should give about 10 miles per gallon in ordinary driving where a reasonable amount of stops are made and a certain mileage is spent in driving around the town or city. Where country driving at a good rate of speed is indulged in, the mileage per gallon should be somewhat above this figure.

It is possible that your carbureter is out of adjustment. By cutting down on the strength of the mixture your fuel bill should diminish.

See that the compression is good and that the valve timing is correct. Push the car over the garage floor, and if it takes much effort, look for friction in the running gear. Possibly the brakes are dragging.

Drive with your spark as far advanced as possible at all times without causing the motor to knock. Also see that the breaker points are in adjustment.

2—We do not believe that a noticeable increase in economy would result from the fitting of an extra set of spark plugs.

3—New plugs can be obtained from the Singer Motor Co., Jackson avenue, Long Island City.

Motor Overheats in 10 Miles

Editor THE AUTOMOBILE:—I have a 1913 six, seven-passenger touring car, that has been giving me a lot of trouble through overheating. It has been run about 4,000 miles and had a tendency, from the beginning, to overheat. I called the dealer's attention to the fact soon after I bought the car, but he told me it would get better after the car had been run a while, but instead has been getting worse, until at the present time I am unable to run any more than 8 or 10 miles before the water begins to boil in the radiator, and that on level country roads. I have taken it to several automobile machine shops without any results. They all declare the timing to be right; the fan seems to be working all right, so is the pump. We can find no obstruction in water lines and there seems to be nothing wrong in the timing or water circulation. The magneto is advanced as far as possible, and I am using as lean a mixture as possible. The car has a world of power and could not work any better up until the time that it begins to boil, when, of course, I have to stop and let her cool off and refill the radiator. The car is equipped with a Rayfield carbureter and Splitdorf magneto.

Ogden, Utah. J. W. L.

—You have named practically all the conditions that might cause overheating, yet since the trouble is still there it would seem that the search has not been thorough enough.

Overheating may be due to a defect in the cooling system, rich mixture, retarded spark, improper lubrication or incorrect valve timing, and possibly a slipping clutch or excessive friction in the chassis.

Under the first head there are several places that there might be difficulty. First determine that the water is circulating properly by emptying enough water out of the system to uncover the return connection to the top of the radiator. Then with the motor running note whether the water flows freely. If it does not, fill the radiator full of water and run the motor until the water boils. Then feel the various parts of the cooling system, noting the relative temperatures. For instance, if there is an obstruction in the return water header, such as a piece of loose rubber, the water on one side of the obstruction will be hot and on the other cool.

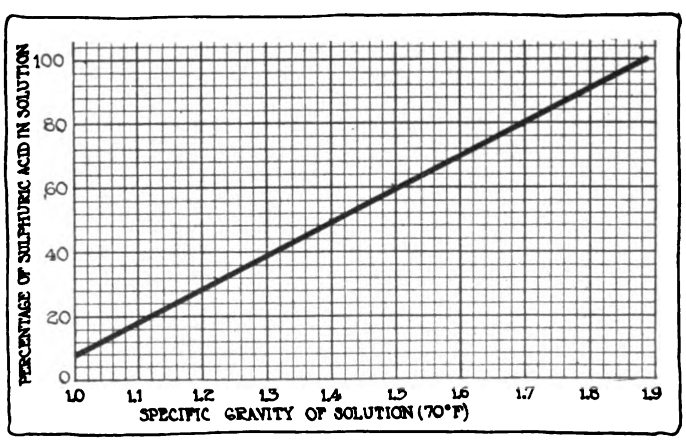

Fig. 2—Curve showing the specific gravity of various percentages of sulphuric acid and water

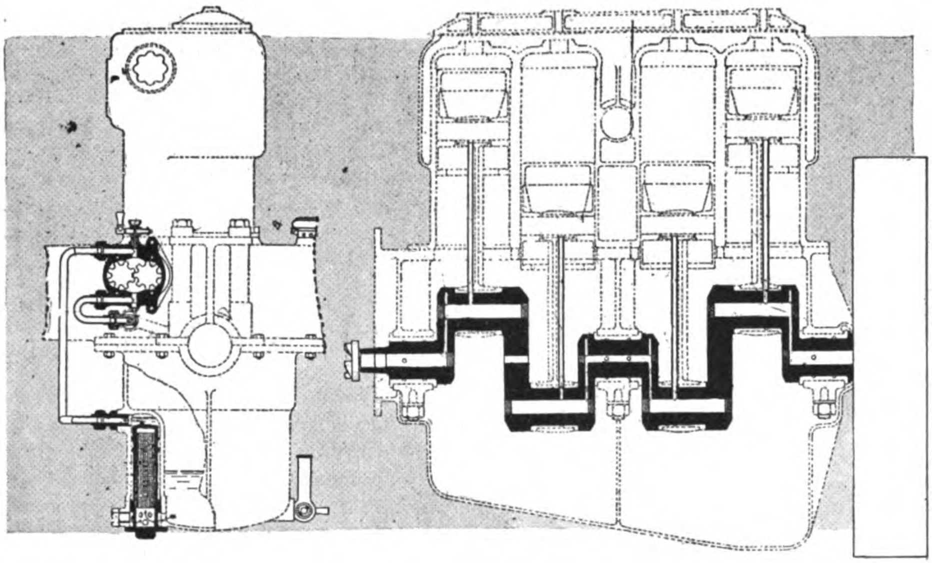

Fig. 3—Two views of the Lancia motor showing the oiling system. It is a force feed type in which oil is carried to all the bearings through a hollow crankshaft

Similarly, if the pump is not operating, due to a broken vane or to a sheared pin that holds the vane to the shaft, then the return header will be very hot, while the lower part of the radiator and the connection from thence to the pump will be cool. If the radiator is clogged up, the top should be very hot and the bottom cooler than usually. It may be that there is sand or some other obstruction in the water jackets. If the trouble cannot be found after diligent search it would be advisable to change the radiator. It may be that the fan belt is too loose.

While you may drive with the spark lever properly advanced and the magneto may be correctly timed, it is possible that the linkage connecting the spark lever with the magneto is loose, so that when the lever is advanced the breaker box is not acted upon.

See that the lubrication system is in proper working order and check up the valve timing.

Installing Spark Advanced on Lancia

Editor THE AUTOMOBILE:—I have recently purchased a four-cylinder 1909 Lancia with runabout body, 3.5 by 4.5-inch bore and stroke, cylinders cast in pairs, Bosch ignition, four-speed gearset.

1—What are the gear ratios? Is fourth speed direct?

2—The engine consumes, as near as I can measure, 1 gallon of oil per 225 miles, and consumes exactly 1 gallon gasoline per 19.6 miles. Are these figures unusual?

3—The magneto is set three-quarters full advance and has no timing control. Unless I get the car rolling at not less than 25 miles per hour it will not take any moderate grade on fourth without knocking. I find I am using third speed more than half the time, and do an excessive amount of changing between third and fourth speeds. I am told by experienced drivers that a car of this type, geared high on fourth speed, is managed differently than the usual three-speed American car, which is geared lower on high speed, and that it is customary to do a lot of gear shifting in place of manipulating the spark.

On third speed the car will take with ease all but the most precipitous hills. It knocks sharply on fourth speed if the throttle is not opened very gradually and delicately.

4—A very pronounced singing comes from transmission on first, second and, above all, third speed, but with four-speed it is noiseless. Does this mean excessive wear? The sound is musical rather than discordant.

5—Please describe the oiling system in full. A gallon reservoir with gauge leads to a rotary pump and thence by numerous leads to the bearings, apparently. Is there a splash system combined? And how is excessive oiling prevented?

LAWRENCE W. WHITE.

Milton, Mass.

—1—Fourth speed is direct. Several gear ratios are used on this car, but the common one is 4 to 1 on high, 6 to 1 on third, 8.5 to 1 on second, 13 to 1 on low.

2—The oil consumption is normal and the gasoline consumption excellent. The oil reservoir in the base of the motor holds over 2 gallons, and this should be changed every 500 miles by removing the plug at the base on the left side, Fig. 3. Take the strainer out and clean it. Put it back and replace the plug. Then flush the motor with kerosene, which is put in through the oil filler opening. Crank the motor over several times until the kerosene has penetrated to every part and then drain it out. After this the base should be filled with oil.

3—The knocking in your motor is not unusual in a car of this type, although it should not be necessary to use third as often as you state. It may be caused, as you suggest, by the early occurrence of the spark, and also to some extent by the carbureter.

In the first place it appears likely that the magneto is set too far in advance. It should be timed so that the breaker points are separating when the mark AA on the flywheel is at the top. But even with the spark so timed the motor may knock, and if the carbureter is found to be in good condition it is advisable to fit a spark advance, as will be described later.

There is no adjustmet to the carbureter except that obtained by filing the edge of the throttle valve, which is a cylindrical one. This should be left to a man that has had experience with this car. Part of the knocking, however, may be the result of dirt in the low-speed nozzle of the carbureter.

This carbureter has a large jet and a low-speed jet. The latter is located at the base of the tube that runs up the side of the main passageway. At the base of this pipe is the low-speed jet, which is so small that daylight can barely be seen through the aperture. Clean away any dirt that may be stopping up this hole and also wash all dirt out of the float chamber. If you have no strainer or sediment trap to catch the water before it reaches the carbureter, it would be wise to install one.

If it is found that the motor still knocks to a noticeable extent you should install a spark advance, as shown in Fig. 4. Return the magneto to the Bosch Magneto Co., 224 West 46th street, New York City, and have a new breaker box fitted, so that the spark can be advanced. Have the arm on the breaker box on the side next to the motor. The charge for doing this is small, but depends on the condition of the magneto, so that no definite figure can be stated.

Bowden Wire Spark Advance Used

A simple mechanism for controlling the movement of the breaker from the steering post is sold by the J. S. Bretz Co., 250 West 54th street, New York City. It consists of a spark lever that is clamped to the wheel, a flexible tube in which is carried a Bowden wire and a bracket to hold the lower end of the flexible tube in place. The spark is advanced by the pull of the cable and the return is accomplished through the spring shown. The friction in the advance lever is sufficient to hold the lever in any position in which it is set. This is accomplished by means of a small helical spring.

The bracket may be bolted to the crankcase, as shown, it merely being necessary to remove one of the bolts holding the two halves of the crankcase together and installing the bracket. Before this is done a hole must be drilled in the end of the bracket.

After the bracket is in place it should be bent by hand until the fitting through which the cable emerges is in line with the eye or hole in the breaker arm.

Be careful to order enough flexible tubing. The cable should be a few inches longer than the tubing.

Next take the spark lever fitting apart and fasten the back of it to the steering post. Then slip the cable in place, fasten it solidly and put the lever back in place. Slip the flexible tubing over the cable and pass the latter through the hole in the dash and fasten the end to the fitting on the bracket attached to the crankcase. With the spark lever at retard and the breaker box in the same position, fasten the cable solidly to the breaker arm by means of the yoked fitting shown. Finally tighten up the nuts that hold the cable in place. It only remains to attach the spring that returns the breaker to retard position and this is fastened at its upper end to the cylinder casting, as shown.

In timing the magneto set it so that with the breaker retarded the points separate when dead center is reached.

4—While the gearset may be noisy, it does not necessarily mean that any replacements need be made. Take off the gear-case cover and examine the shafts for play and note whether the teeth are in good condition. If any of the gears are very badly worn they should be replaced, and if there is any large amount of play when the shafts are shaken by hand, new bearings will be needed.

5—Lubrication is accomplished by a pressure system, Fig. 3, which delivers oil to all the bearings. The main bearings are lubricated directly from the main oil pipe. The crankpin bearings obtain oil from the main bearings by means of a hollow crankshaft, and from these bearings the oil is fed to the wristpins through tubes that are attached to the connecting-rods. From here the oil flows to the cylinder walls.

To go more into detail. The oil passes from the main feed pipe by means of canals cut into the main bearings, to the crankshaft bearings and to the timing gears. It continues to flow and enters the crankshaft itself through the small holes shown in the journals. The oil then passes through the crank arms and out into the copper tubes which carry it to the wrist-pin bearings and from thence out through the wrist-pins to the cylinder walls.

Oil circulation is maintained by a gear pump mounted on the back end of the camshaft. The pump obtains its supply from a 9-gallon reservoir in the base of the crankcase.

Pressure is automatically regulated by means of a bypass valve or oil pressure governor, at the side of the crankcase. The excess pressure opens this valve and allows the surplus oil to return to the reservoir.

The height to fill the crankcase to is determined by means of the stand pipe, or drip cock, depending on the model, at the side of the crankcase.

Double-Acting Motor Complicated

Editor THE AUTOMOBILE:—I would like to have your opinion of a double-acting four-cycle motor. I have been granted a patent on a motor that receives a firing impulse above and below the pistons.

Richmond, Ind. EDWARD L. YOUNG.

—While we do not know anythig about your particular motor the general objections to double-acting motors for automobiles are that it is too difficult to cool the stuffing box required around the piston rod; that there is danger of pre-ignition and warping of the piston due to the fact that it is exposed to intense heat on both sides; that such a motor must be a great deal higher, due, first of all, to the fact that there are two combustion chambers in the same vertical line, and also because a cross-head construction must be used.

To Cut Sheet Metal in a Vise

Editor THE AUTOMOBILE:—I have seen many a man go through all kinds of performances in cutting a strip off of a piece of thin sheet metal. Some use hack saws, some lay the sheet metal flat on a block of lead and drive a chisel through along a scratch line, and others will bend the sheet along the aforesaid scratch to an acute angle then bend the sheet straight again, etc., etc., until the break comes along the desired place.

The simplest way to cut sheet metal, provided it can be inserted into a vise, is shown in Fig. 5. Clamp the edge of the vise jaws along the line to be cut, and with the cutting edge of the chisel pressed down against the top of the vise, but as nearly at right angles as possible to the sheet metal, drive the chisel along with the hammer.

The cut made in this way is clean, accurate and easy. If you have never tried it, its simplicity will surprise you.

New York City. W. F. SCHAPHORST.

Manufacturer of Bergdoll Motors

Editor THE AUTOMOBILE:—Please publish in your next issue who manufactures the Bergdoll motor which is used in the Bergdoll 40 car.

St. Louis. E. EDWARDS.

—Write the Louis J. Bergdoll Co., Philadelphia, Pa.

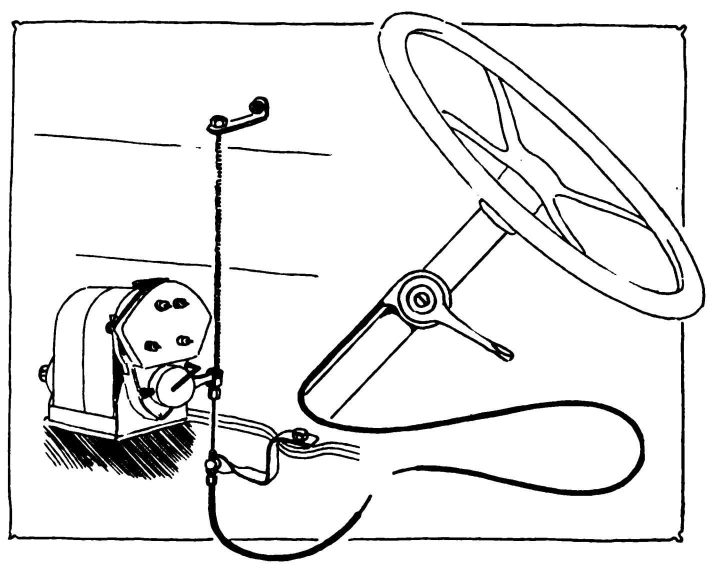

Fig. 4—Spark advance installed on 1909 Lancia. The lower end of the flexible cable is held in a bracket attached to the crankcase. This bracket is bent into shape by hand. The breaker is returned by means of the spring which is attached at its upper end to bracket that is bolted to one of the studs on the exhaust plate.

The Engineering Digest

Elements in Gearing and Clutches Serving to Avoid Jerky Starts and Needless Wear of Tires

EDITORIAL NOTE—The study which is presented herewith relating to the mechanics involved in the starting of a vehicle from an internal-combustion motor, is believed to be the first of its kind. The author seems to feel the difficulties and to grope his way toward definite conclusions. The language in the German original is super-condensed, uninviting and non-committal. But the equations which the author has gathered and the figures deduced from them to show the extent of the slip-movements involved in starting a vehicle, form an excellent basis for further attempts at digging out of the subject what there should be in it with regard to the proper relations of clutches, transmission gears, vehicle weights, motor sizes and speeds and several minor design features—a large subject which has been especially neglected, so far as theory and practical refinements are concerned, and which is especially important with regard to vehicles intended for carrying heavy and variable loads.

If, in contrast to what the author means to convey, it may be shown that heavy loads in reality may be started easily from a small high-speed motor working through any ordinary clutch—on average or poor roads and without slipping of the driving-wheels—or if, on the other hand, the opposite is shown to be true, something would evidently be gained toward getting at the reasons for the very different starting-qualities actually observed in different makes of trucks, delivery wagons and omnibuses. The essay of Mr. Achilles conveniently supplies some of the reasoning-material which might be used for this purpose.

The question of the feasibility of using small motors of high speed for heavy work is among the most important ones on which an elaboration of the subject would shed light.

WHEN a motor vehicle is so constituted that skilful slipping of the clutch and manipulation of the throttle are required in order to avoid jerky starts or the spinning of the driving-wheels, with the tires in frictional contact with the ground, it is to that extent less perfect than one which can be handled more carelessly or less skilfully without undesirable consequences. F. Achilles, an engineer of Mannheim, Germany, examines the factors which must be considered in the design of cars with reference to this matter, assuming at first that the motor runs at a certain regular speed and that the clutch has no slip. The argument may be rendered as follows:

It is necessary to know the difference in the distance covered by the actual acceleration of the vehicle from a standstill and that which would be covered if the driving-wheels followed the motor, without retarding it, during the time occupied by the acceleration.

If the motor at the starting runs with N turns per minute and the factor of total speed reduction on the lowest gear is U, the driving-wheels make n turns, n being equal to N divided by U. With a wheel diameter D the vehicle would then have a uniform speed of V meters per minute, V equalling $\pi D n$. Conforming with the custom of having V stand for meters per second, we have $V = \frac{\pi D n}{60}$. The distance S covered by the vehicle in the time T is VT.

On the other hand, the motor applies a torque which, with the transmission ratio and the diameter of the driving-wheel duly considered, gives a pull Z at the point of tire contact with the ground. After deducting the value representing the starting-friction there remains a surplus Z_1 for the acceleration of the vehicle. The value of the acceleration P involves the weight of the vehicle G and the acceleration factor $g = 9.81$ meters (corresponding to 32.20 feet), making $P = \frac{Z_1 \times 9.81}{G}$, and with this acceleration there is in the time T covered a distance $s = \frac{PT^2}{2}$.

For a given time T it is thus simple to figure the difference in the distances. But it is of more importance to know what the maximum difference in the distances amounts to and at what time it occurs. When P and T are given, these are the factors to be determined. Calling the maximum difference Y, one has $Y = S - s = VT - \frac{PT^2}{2}$, in which the greatest value for Y is obtained (according to simple maxima-and-minima rule) when $T = \frac{V}{P}$. Inserting this value, one has

$$Y = \frac{V^2}{P} - \frac{V^2}{2P} = \frac{V^2}{2P}$$

Still more directly of interest than the difference in distances at the circumference of the driving-wheel is perhaps the same factor expressed in revolutions of the driving-wheel. In other words, the difference is to be expressed between $n_v = \frac{VT}{\pi D}$, which is the number of revolutions which the driving-wheel would make in the time T from the beginning of the starting with the vehicle speed V and, on the other hand, $n_p = \frac{PT^2}{2\pi D}$, being the number of revolutions of the driving-wheel in the time T with the acceleration P beginning at the start. The maximum value is found exactly as above, with insertion of the value for $T = \frac{V}{P}$ which gives the maximum value for the difference sought, and the latter is thus seen to be $Y_n = \frac{V^2}{2P\pi D}$

To illustrate the meaning of these general values it may be

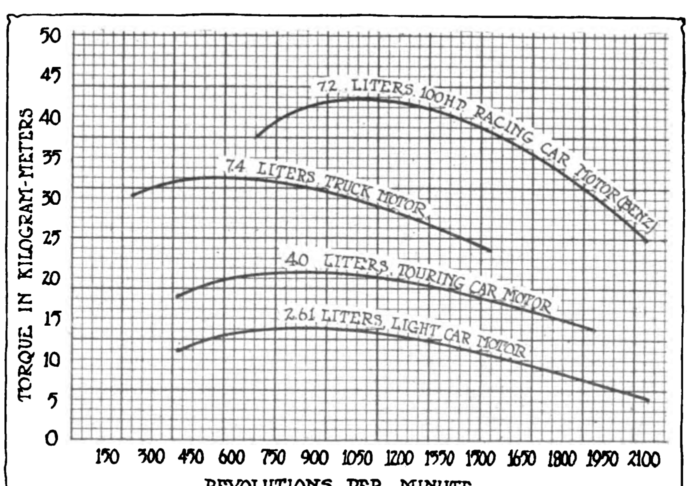

Fig. 1—Comparative torque curves of different vehicles

advisable to give also a general example. Let it be assumed, then, that a motor vehicle has a wheel diameter $D = 1$ meter and with its lowest admissible motor speed and its greatest speed reduction gives a uniform vehicle speed V of 1.5 meter per second and by its pull gives an acceleration $P = 1.5$ meter per second. With these data the figures obtained from the preceding equations may then be arranged in the following table:

TIMING OF MAXIMUM SLIP IN STARTING

Time from beginning of start T = (seconds)	1/10	1/5	¼	½	¾	1	1¼	1½	2
Distance covered S = ...(meters)	.15	.3	.375	.75	1.125	1.5	1.875	2.25	3.0
Distance covered s = ...(meters)	.0075	.03	.047	.1875	.425	.75	1.175	1.7	3.0
Difference S—s = ...(meters)	.1425	.27	.328	.667	.70	.75	.70	.55	0
Revolutions with motor speed V; n_v =	.048	.096	.12	.24	.36	.48	.60	.72	.96
Revolutions with acceleration P; n_p =	.0024	.0096	.015	.06	.14	.24	.38	.54	.96
Difference, $n_v - n_p$ = ... (revolutions)	.0456	.086	.105	.18	.22	.24	.22	.18	0

In this example, it will be noticed, the maximum differences in the movements occur when $T = 1$ second.

It is now necessary to compare practice with the principles of movement expressed in this schedule of figures. In reality the motor is not coupled rigidly with the transmission gear. The friction clutch creates the possibility for reconciling the differences in movement. When it is considered, however, that these differences are U times greater in the clutch than in the driving-wheels, it is plain that they may tax the clutch surfaces unduly. In the case of the scheduled example, where U is 16, as common for touring cars, a maximum difference of $.24 \times 16 = 3.8$ revolutions is obtained for the driving and the driven portions of the clutch. In other words, during the first second of the start the driven portion of the clutch must be allowed to slip 3.8 revolutions.

[While the author means to show principally that it is desirable in the designing of a car to take close account of the relations between speed and torque of the various revolving parts, in order to be able to proportion the clutch and the gears, and even the wheels, suitably for the work expected of the vehicle and its driver, it is clear that his argument bears with equal force upon the advantages to be derived by bringing all slip movements under the most facile control without resorting to extraordinary maintenance care of the slipping surfaces or to extraordinary demands for operative skill on the part of the driver. Indirectly the merits of a good hydraulic clutch, especially for the heavy load-carrying vehicles in which the torque of the wheelshafts necessarily must be considerable, thus enter in the subject, as well as the question of the preference for one or another of the standard types of clutch, according to the nature and purposes of the vehicle involved in each case.—Ed.]

How Tires Are Affected

The movement required of the clutch is of considerable importance. But there are other elements in which the required movements can be equalized. The yielding properties of rubber tires, especially air tires, admit of some displacement in the direction of motion. But the principal element of this nature comes into existence through slipping of the driving-wheels on the road after overcoming the road friction. The condition for having this element come into action is that the driving-pull at the tire circumference, with the lowest gear in mesh and the motor at the lowest speed which may be depended upon to start the vehicle, is in excess of the resistance to the sliding of the two wheels. If this condition exists and is aggravated by lack of skill on the part of the driver it becomes the cause for abrasion of the tires at every start.

On the whole, in order to be able to start at all, there must be the possibility for

(1) either slipping the clutch to allow for the difference in movement, and the clutch spring pressure must in that case be adjusted to correspond to the torque resistance;

(2) or slipping of the driving-wheels on the road surface, and in that case the road friction and the required pull at the tire circumference must correspond;

(3) or a movement in the transmission gearing admitting of the equalizing of the different movements.

In order to know in advance how a certain vehicle will act at the starting, the numerical value of the following factors must be known:

(1) Total weight G of the vehicle; (2) G_w, being the portion of G resting upon the driving-wheels; (3) diameter of driving-wheels D; (4) Factor U of speed reduction in the transmission from motor to wheelshaft on lowest gear speed; (5) power development of the motor throughout the lower range of motor speeds.

With regard to the latter factor, which must take the form of a schedule of figures or a torque curve like those shown in Fig. 1—giving comparative torque curves for several vehicles—the well-known fact is to be noted that each motor produces its highest pull and torque at a certain number of revolutions depending in each case on its design (see Fig. 1). At the starting, under the throttle, the number of revolutions will drop till the pull produced by the motor corresponds to the frictional resistance to rotation at the tire circumferences. At that moment the highest available pull of the highest torque is realized.

The maximum motor torque is to be figured from the mean piston pressure p, which may be done in the simplest manner by counting on $.8\ p$ for each liter of cylinder volume. And from the number of kilogram-meters motor torque so obtained the effective torque can be figured under the assumption of a mechanical efficiency in the transmission of 70 to 75 per cent., and the driving pull at the tire circumference can be determined from the wheelshaft torque when the wheel radius is known.

The starting speed of the vehicle must be determined from the number of motor revolutions giving the necessary pull.

Finally there is required knowledge of the friction coefficients on different road surfaces. These figures may be about as follows:

Ordinary macadam—rubber tires 50 to 60 per cent.; iron tires 40 to 50 per cent.

Better macadam—rubber 40 to 50 per cent.; iron 30 to 40 per cent.

Stone pavement—rubber 30 to 40 per cent.; iron 25 to 30 per cent.

Wood blocks—rubber 30 to 35 per cent.; iron 20 to 25 per cent.

Asphalt—rubber 20 to 30 per cent.; iron 15 to 25 per cent.

With this material arranged it is possible to illustrate the previous reasoning by definite examples. Let the first one refer to a light 10-tax-horsepower car with a cylinder volume of 2.61 liters. Out of the total weight of 1,500 kilograms, everything up, 900 kilograms come on the rear axle. Let the wheel diameter, including tire, be 820 millimeters and 16 the factor of the transmission ratio on low gear. On the supposition of a mean effective piston pressure of 6.5 kilograms per square centimeter there is found to be a motor shaft torque of 13.6 kilogram-meters and at the tire circumference, with the 75 per cent. efficiency in the transmission and the transmission ratio of 1 to 16, a torque of 162 kilogram-meters. Out of this torque a pull of 400 kilograms becomes available at the tire circumference, and, figuring on using about 50 kilograms to overcome the starting-friction, there remains a pull of 350 kilograms for acceleration. This has an acceleration value $P = \frac{350 \times 9.81}{1,500} = 2.3$ meters per second.

As it is further to be assumed that the maximum torque is furnished by the motor at 600 revolutions per minute, the coupling should take place at this speed, and the vehicle speed V corresponding to this motor speed, being $V = \frac{600 \times \pi \times D}{16 \times 60} = 1.6$ meter per second, is the one to be considered in the figuring.

With these figures the time T after which the difference between S and *s* reaches maximum is determined as before by giving T the value $\frac{V}{P} = \frac{1.6}{2.3} = .7$ second, because this value for T gives maximum value to $Y = S - s$ in the equation $Y = S - s = VT \frac{PT^2}{2}$

The greatest difference Y in road distances—according to whether motor speed or available torque is made the basis for the determination—is on the same plan found to be

$$Y = \frac{V^2}{2P} = \frac{1.6^2}{4.6} = .55 \text{ meter}$$

and the greatest difference in the movements as expressed in revolutions Yn of the driving wheels, being Y divided by πD, is seen to equal $\frac{.55}{\pi D} = .215$ revolution.

The difference in revolutions of the motorshaft is of course 16 times as large, or $16 \times .215 = 3.45$ revolutions.

TABLE SHOWING VARIATIONS IN CONDITIONS FOR USE OF CLUTCH

Type of Vehicle	40 H.P. Car	70 H.P. Car	100 H.P. Benz Racer	3-Ton Truck	5-Ton Truck	6-Ton Military Truck with Trailer
Cylinder volume, liters	4.0	8.0	7.2	5.2	7.4	7.4
Vehicle weight, kilograms	1,750	2,200	1,540	5,600	9,000	12,000
Weight on driving-wheels, kgs	1,050	1,350	860	3,300	5,400	4,800
Mean effective piston pressure referred to motorshaft, in kilograms per square centimeter	6.5	6.5	7.0	5.5	5.5	5.5
Torque of motorshaft, in kilogram-meters	20.8	41.6	40.25	22.8	32.5	32.5
Total transmission ratio, U	15	10.25	6.65	37	37	57
Torque of wheelshafts, kilogram-meters	235	325	200	630	900	1,300
Diameter of driving-wheels, meters	.880	.935	.810	.930	.930	1.030
Pull at the wheelrims, kilograms	535	690	495	1.350	1.950	2.550
Co-eff. of road friction corresponding to driving-pull, per cent	510	510	570	410	360	530
Available acceleration P, meters per second	2.75	2.95	3.4	2.1	1.85	1.80
Motorspeed giving max. torque, N, rev. per minute	700	500	800	400	400	400
Vehicle speed corresponding to N, meters per second	2.15	2.35	5.1	.66	.66	.38
Time T of max. slip movement, $T = \frac{V}{P}$, in seconds	.75	.80	1.5	.32	.36	.21
Max. road difference, $Y = \frac{V^2}{2p}$, in meters	.83	.93	3.75	.104	.117	.04
Max. diff. in wheel rev., $Y_n = \frac{V^2}{2P\pi D}$	.3	.315	1.46	.036	.04	.012
Max. slip in clutch, in revolutions	4.5	3.3	9.75	1.25	1.5	.73

If it is further considered that a pull of 400 kilograms can be applied through driving-wheels under a load of 900 kilograms only when the co-efficient of road friction gives a minimum resistance against slipping of the wheels of $\frac{400 \times 1,000}{900} = 44.5$ per cent., the inferences relating to practical operation of such a car as referred to in the example may be formulated as follows:

With a rigidly acting clutch the driving-wheels will slip to the extent shown on a road surface having a friction coefficient exactly corresponding to the torque required for starting the vehicle. On roads with smaller friction the slipping will occur at the application of a smaller torque, and in considerably aggravated degree because under that condition the acceleration is smaller. On roads with higher friction the vehicle will remain on the spot if the clutch cannot be slipped the required amount.

The appended table gives numerical values for the factors of interest, as applied to six other standard automobile types.

It is left to the reader to draw conclusions from these figures with regard to the properties required of the clutches and the sizes of motors by which the necessary starting torque may be produced at a motor speed sufficiently low not to tax the clutches actually available too severely.—From *Auto-Technik*, July 4.

Hydraulic Clutch with Ball Pistons Made in England

CONSIDERABLE activity is noticed, mainly in this country and in England, aimed at the improving of hydraulic mechanism for the transmission of power and foreshadows perhaps the time when cheap and very durable devices of this class will take the place in automobiles of friction clutches and toothed transmission gears. If the mechanical efficiency of the perfected hydraulic element may not be expected to equal that of refined gears when these are new, it may on the other hand be relied upon to remain practically the same for a number of years, while cheapness and lightness must be assured in the final outcome through the avoidance of costly machining and hardening of parts and through the equable distribution of stresses. The use of packings, to obviate leakage along the shafts, is still an important drawback in hydraulic devices of small dimensions, but the improvements of recent years usually include provisions for returning leaked-out oil to the circulation system—as, for example, in the Hele-Shaw hydraulic gear for ships and motor trucks—and thereby allow the use of packings which are relatively loose and not subject to much wear.

It is naturally in the easier applications of the hydraulic principle that the improvements take the most acceptable form. Pumps with fixed capacity, for each shaft revolution, and hydraulic clutches—from which only a graduated slip but not a changeable torque is required—are first to bid for serious practical attention from automobile builders, while the more complicated devices meant to take the place of the four-speed gearbox still present themselves with too many interrogation points to the critical engineer bent on safe results.

The hydraulic clutch becomes of special interest in connection with the design problems submitted by Mr. Achilles of Germany in the preceding article, relating to the starting of vehicles and clutch maintenance. A clutch of this class is one of four hydraulic mechanisms brought out by R. F. Carey of Variable Pumps and Motors, Limited, of England, and the main features of its design are shown in Fig. 2. One of the innovations is the use of steel balls as pistons, and this is also found in the three other mechanisms designed by him, comprising a pump with fixed capacity, one with variable capacity and a variable-torque transmission.

The driving-shaft or rotor A of the clutch is fixedly secured to the steel cylinder F which is formed with six radial pump bores containing snugly fitting steel ball pistons and is mounted eccentrically in the driven casing, comprising parts G and B, by means of ball bearings HH. Between the two portions of the casing there is mounted the hardened steel ring J which forms a track limiting the in-and-out movements of the steel balls, eccentrically, so as to cause the balls to reciprocate in the pump bores when the rotor is revolved. This track is held in position by the same bolts that hold G and B together. Centrifugal force holds the balls against the track, and the friction with it gives the balls a rotary movement while they are being reciprocated. The apparatus, in the dimensions shown in the drawing, is intended to transmit 20 horsepowers at 1,000 revolutions per minute.

In the position shown the casing will remain stationary when A is revolved, the oil simply circulating among the cylinders, but by moving the clutch ring C to the left the valve body D, whose inner end is a cylinder ground to fit in a central longitudinal bore in the rotor, is moved by means of the transverse pin K and obstructs more or less the communication from one pump bore to another. Pressure then rises in those bores in which the steel balls are being driven inwardly by reason of their relations to the track J, and the friction created with the track eventually causes the casing to be carried along with the rotor. The more completely D obstructs the oil flow the less is of course the slippage which takes place. When D separates the bores entirely, except for the internal leakage along the contacting surfaces, B will move at almost the same speed as A. At this point the connection can be made positive by moving D a little further, as then the dog clutch L is brought into engagement with corresponding dogs MM on the rotor, the slowness of the relative movement of the two parts rendering it easy to effect the engagement without clash of the dogs.

The box E carried on the rotor shaft is connected to an oil reservoir and is used for filling the apparatus. It also provides for expansion of the oil and for the displacement of oil which is due to forcing the body of D into it.—From *The Engineer*, London, August 14.

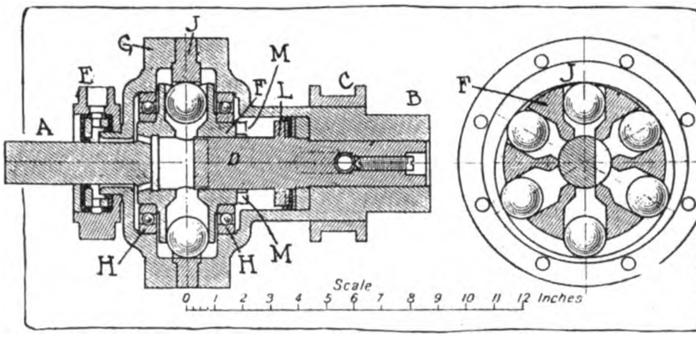

Fig. 2—Carey's hydraulic clutch with balls as pistons

How Low's Small-Size High Compression Motor is Progressing

WITH the economical production methods instituted by the American automobile industry—and now imitated more or less thoroughly in all manufacturing countries—creative engineering, and therefore also designing, is necessarily two or three years in advance of manufacture, being concerned with that which may become embodied in popular motor vehicles two to three years hence. From this viewpoint it is to those constructions and construction features which have not yet reached common acceptance but which nevertheless seem to possess a good fighting chance that most attention is paid in these DIGEST columns, rather than to fully accomplished and recognized improvements. Among the tentative constructions claiming notice the small-size motors designed by Dr. Low of England hold a prominent place because they are operated with very high compression and represent a development promising fuel economies for small and light motors similar to those accomplished with Diesel motors in another field. With regard to the progress made with the Low motors, F. X. Schmelz, a German engineer, writes from London substantially as follows:

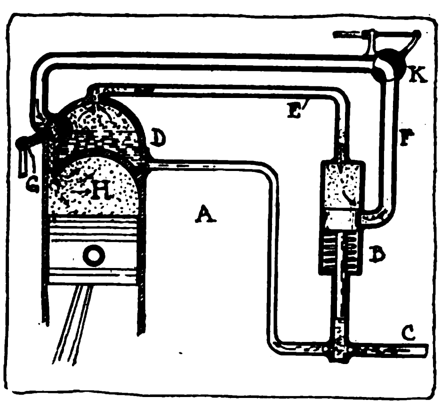

Fig. 3—Scheme of Low motor

The high-pressure motor constructions developed by Dr. Low have passed through the experimental stage and before long [this was written before war began] several models adapted for automobiles, motor trucks and aeroplanes will be placed in the market. The patents have been acquired by a strong syndicate and this is at present working with the inventor on the last refinements intended to make the motors foolproof. A number of well-known English motor firms are also experimenting with these motors and the military authorities are strongly interested in them, mainly with aeroplane service in view.

The Low motor now works on the four-cycle system. [An account of the previous stage in its development may be found in THE AUTOMOBILE of March 13, 1913, page 632.] The suction stroke takes in only atmospheric air which is brought to a tension of 35 atmospheres by the compression stroke. This high compression has made the use of a steel sleeve for the cylinders necessary, as with the ordinary cast-iron cylinders the air leaked out through the walls. A still more forcible reason for making the walls absolutely inpenetrable is that gasoline vapor under a pressure of 70 atmospheres is stored in a jacket surrounding the cylinder and if this could be forced into the cylinder through its wall an explosion during the compression stroke would be the result.

The accompanying diagrammatic sketch, Fig. 3, indicates clearly how the gasoline is taken into the jacket, how it is vaporized and how it is finally admitted to the cylinder. The jacket is in this sketch represented by the tube A and is connected at one end with a special plunger pump B and with the gasoline tank—by the pipe C—while the other end connects with a dome D over the cylinder head. From the dome a pipe E leads to the space above the piston in the pump barrel. Another pipe F branches from this barrel near the lower end of the plunger stroke and leads by way of throttle K to a valve G giving admission to the combustion chamber H. The starting of the motor is effected with small compression and magneto ignition, as in ordinary motors. The gasoline jacket is filled with gasoline by the first few revolutions and, as the motor has been preheated, this fuel is vaporized and raised to high tension. When this has been accomplished the mechanism is adjusted to produce full compression and thereafter only air is drawn in and compressed. In the first experimental motors the piston at the end of the compression stroke impinged against a needle valve which admitted high-tension vapor to the cylinder, but this arrangement did not admit of speed changes by regulation of the fuel feed, and therefore the rotary valve G was devised which could be regulated mechanically and imparted

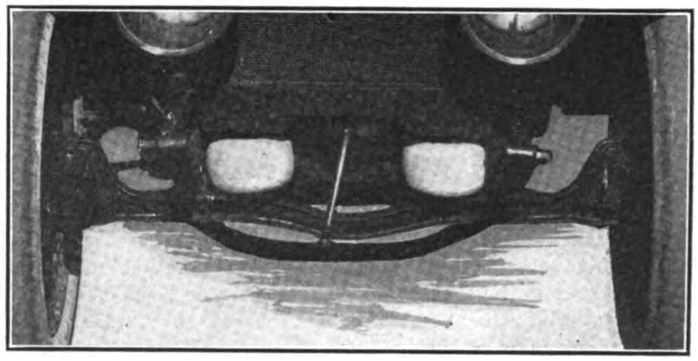
Pneumatic Spring Gives Varying Resiliency

Cox Air Cushions Automatically Increase Pressure with Load—Frame Level Constant



Cox pneumatic cushions attached to the front of a car

RESILIENCY that varies with the passenger load is obtained by the pneumatic cushion spring manufactured by the Cox Pneumatic Cushion Co., New York City.

As will be noted in the accompanying illustrations the spring consists of a ball cushion several inches in diameter that is put between the axle and the frame in the place of the ordinary leaf spring. This cushion is connected at its upper end or neck to a large auxiliary tank and when the cushion is compressed, air is transferred from it to the tank. The tank is so large, however, in comparison, that the pressure rise is negligible.

Accommodation to varying loads is automatically obtained by a regulator which changes the pressure in the auxiliary tank and cushion by allowing air to flow from the main tank to the auxiliary tank. The pressure in the main tank is maintained by a pump. The pressure in the auxiliary tank and air cushions varies from about 20 to 30 pounds depending on the load. How the regulator works will be described later but it automatically holds the frame, when the car is at rest, at a certain distance from the ground regardless of the load.

The cushion is made from several layers of rubber and tire fabric and resembles the ordinary tire casing in construction.

The life of these cushions is from 2 to 3 years although in some cases it has been more than this. A leaky cushion is unheard of.

Only the pressure in the rear pair of cushions is varied, the load on the front of the machine being so nearly uniform that the pressure is maintained constant by using a separate tank. That is not connected to the pressure regulator.

Pressure Fixed Before Car Starts

The pressure in the rear cushions is brought to the required amount, before the car starts. But after the machine is in motion the pressure cannot be changed except the small amount due to the compression of the cushions. When the axle is raised on striking a bump, the cubical capacity of the cushion is reduced and some of the air is transferred to the air tank. The walls of the cushion fold back over the conical plungers that support it at the top and bottom, thus increasing the supporting area in accordance with the violence of the shock rendered. Each fraction of an inch of axle movement thus increases the resistance, and the axle, moving upward, gradually slows down and stops.

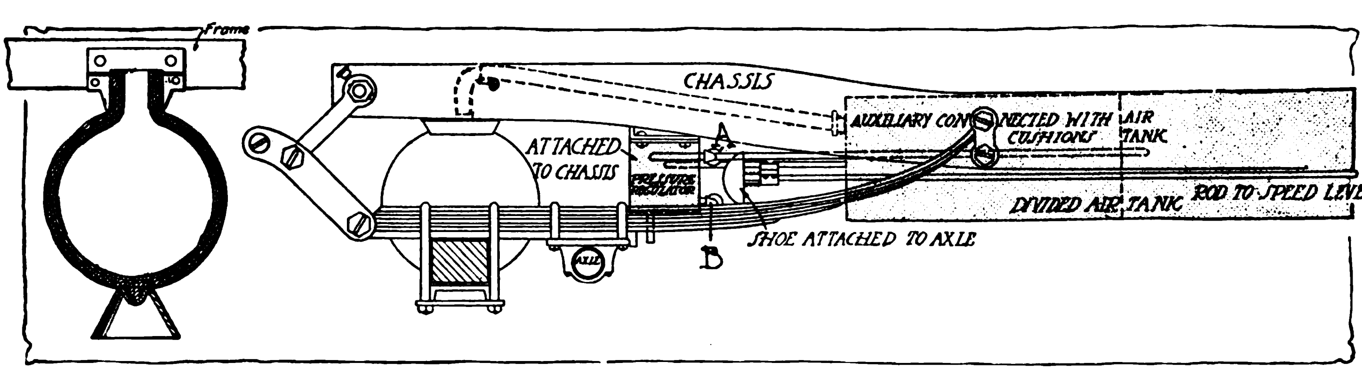
This is the principle of the pneumatic tire, and, by comparison, the spring and plungers take the place of the road and tread of the tire, the volume of air in the auxiliary tank being more than equal to the volume of air in the tire. This increase of the supporting area of the springs is very much along the same lines as the tire increases its supporting area when it flattens out on the roadbed under an added load or shock. Thus it will be observed that shocks caused by road obstructions are sustained by an automatic increase in the contact area of the springs with the plungers. The auxiliary air reservoir, owing to its large volume of air, relative to the small amount of air displaced from the springs, obviates any perceptible increase in the air pressure while the vehicle is running, thereby allowing a long travel of the plungers into the spring cushion.

Pressure is increased according to the load by means of the regulator, already mentioned, the main part of which is attached to the chassis frame. What is known as the shoe, however, is fastened to the axle. It is the relative movement between these two parts of the regulator that varies the pressure so as to keep the frame level constant.

This shoe is moved out of reach of the rollers when the car is started, by being connected to the change gear lever. If this provision were not made, the relative movement of the axle and frame would cause a transfer of air on a rough road that would prevent the working of the device.

When passengers enter the car, the frame sinks a certain

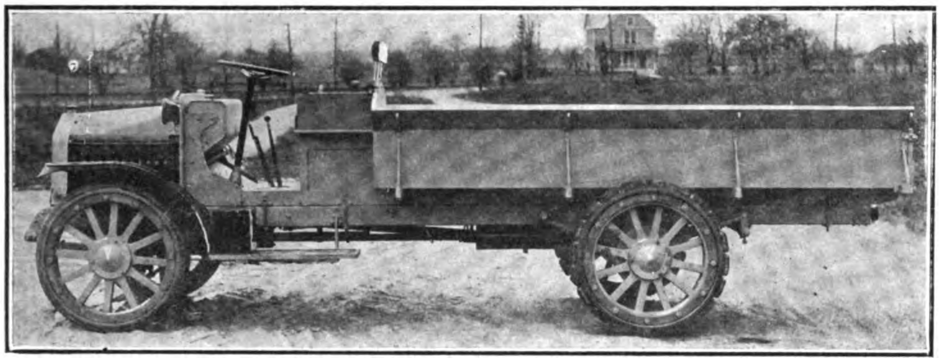
(*Continued on page* 455)



Left—Section through air cushion showing method of attachment and support. From the conical shape of the plungers, it will be noted that when the cushion is compressed, it folds back over these plungers and the effective area is increased.

Right—Cushion attached to rear of car. The spring has been sawed off and a new rear shackle put on. The cushion is placed directly behind the axle. A pipe connects the cushion with the low pressure, or auxiliary side of the air tank. The movement of air from one to the other is free and uninterrupted, when a bump is struck. The right side of the tank contains high-pressure air which is introduced into the auxiliary tank by the regulator when load is put on.

Fremont-Mais Has Double Reduction Axle



Fremont-Mais 1.5-ton truck

Made With Two Frame Lengths—Chassis 1.5-Ton—Flexible Frame and Unit Power Plant

THE new 1.5 ton truck, known as the Fremont-Mais is notable for the flexibility of the frame and of the various power units in relation to it, and for the unit power plant, and double reduction rear axle.

The truck is the design of Albert F. Mais and is manufactured by the Lauth-Juergens Motor Car Co., Fremont, O. It is made in two wheelbase lengths, 132 and 144 inches.

The frame is of pressed steel, substantially straight from end to end, with integral spring horns in front. It is designed to carry but few cross-members, these being designed with integral gussets.

The power plant is placed well forward under a blocky hood, with the radiator in front. It consists of a Buda truck type motor, 3¾ by 5½, fitted with Eisemann fixed-spark ignition and pump cooling; a Warner leather-faced cone clutch, and a Warner three-speed selective gearset, all three being rigidly secured to one another and suspended from the frame at three points. From the gearset the power is transmitted to the rear axle through a shaft with two universals.

Internal Gear Drive Used

The rear system consists of a specially-designed internal-gear-driven rear axle, the axle proper being an I-beam which carries the brake flanges. Bolted rigidly to this is the jackshaft, consisting of a bevel-driven differential driving spur pinions in each brake flange. The third member enters the differential housing through a bearing in the axle web. In the brake drums are internal teeth which mesh with the spur pinions, thus taking the drive through a secondary reduction. The spring pads are of liberal size and integral with the axle beam, the springs being relied upon to take both torque and propulsion.

Foot brakes are located in the rear drums, the hand brake being on the driving shaft, just in front of the axle. The brake and gearshift levers are both in the center, the steering wheel being located to the left. Although the spark advance is fixed, there are two levers on the steering wheel, one for the throttle and the other for the air adjustment of the carbureter.

A storage battery provides current for the electric side and tail lights. The wheels are of the square-spoked pattern, having 36 by 3½ front tires and 36 by 5 in the rear.

Pneumatic Spring Gives Varying Resiliency

(*Continued from page* 454)

amount, which brings the shoe, which is attached to the axle and moves with it, into contact with the roller A. This action opens a valve between the pressure tank and the auxiliary tank. Pressure flows from the former to the latter, until there is sufficient in the system to bring the frame up to the normal level, when the roller moves out of contact with the shoe and the pressure is shut off. Similarly, if a passenger gets out of the car, the frame will rise and the shoe will press against the roller B, and open a valve that allows the pressure in the auxiliary tank to flow into the atmosphere.

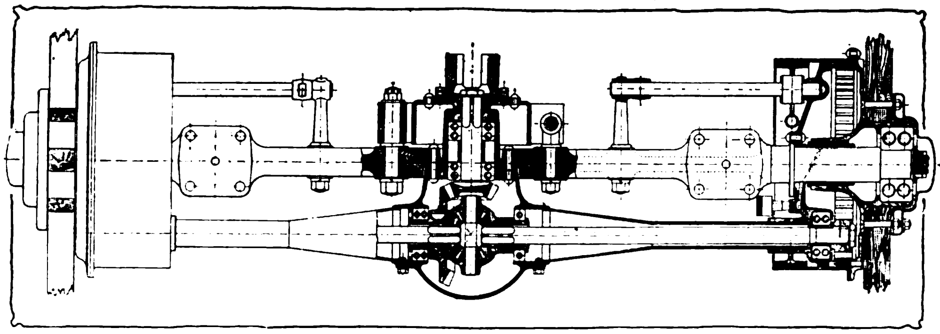
The system may be applied to any car by cutting off the rear ends of the rear springs and putting in a shackle with a double joint in it, thus allowing free vertical movement but no lateral. At the front, all the leaves but two are removed, these being merely to hold the car against side sway. Thus the spring is used as a guiding member. On new cars a solid bar would replace the spring.

A representative of THE AUTOMOBILE had a ride in a touring car equipped with these springs and found that the car rode smoothly on cobblestones at all speeds.

It is claimed that as much as 18,000 miles can be obtained from a set of pneumatic tires due to the superior resilience of these springs.

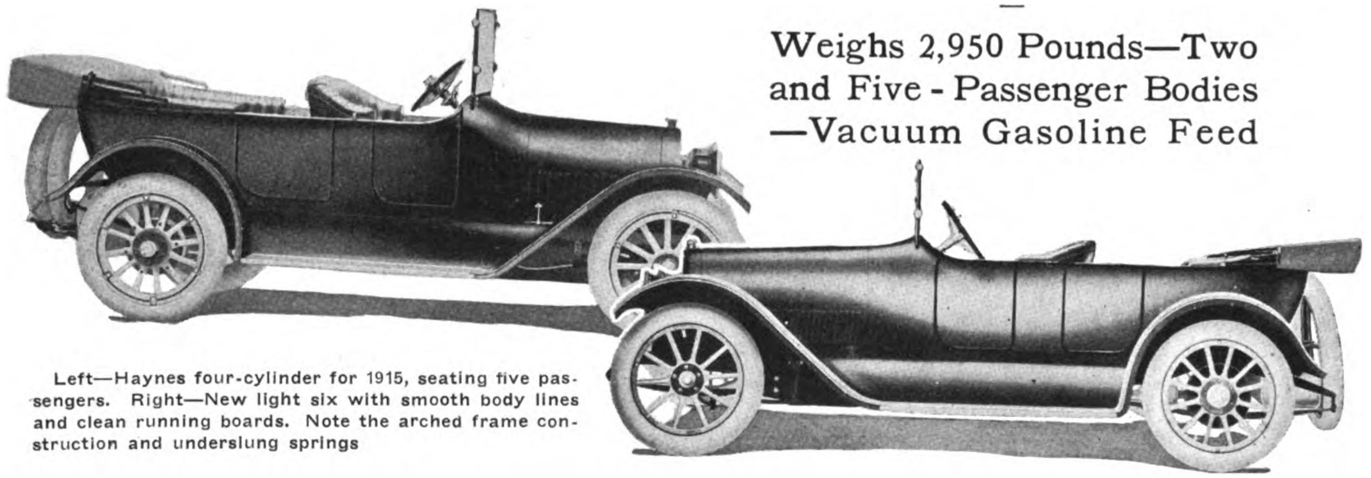
A prominent concern in New York that has a great many trucks, has been using this spring on one of its trucks for over 2 years, and greatly increased tire mileage and reduced wear and tear on the machinery have resulted.

Floating rear axle of the double reduction type used on the new Fremont-Mais truck. The second reduction is in the shape of a driving pinion and internal gear at the wheels. The load is carried on an I-beam axle and the differential gearing and driving shafts are in a separate housing at the rear. Note that the hand brake is located directly in front of the I-beam axle. It is a contracting band type, while the foot brakes expand in drums attached to the wheels.



New Haynes Six Sells for $1,485

Weighs 2,950 Pounds—Two and Five - Passenger Bodies —Vacuum Gasoline Feed



Left—Haynes four-cylinder for 1915, seating five passengers. Right—New light six with smooth body lines and clean running boards. Note the arched frame construction and underslung springs

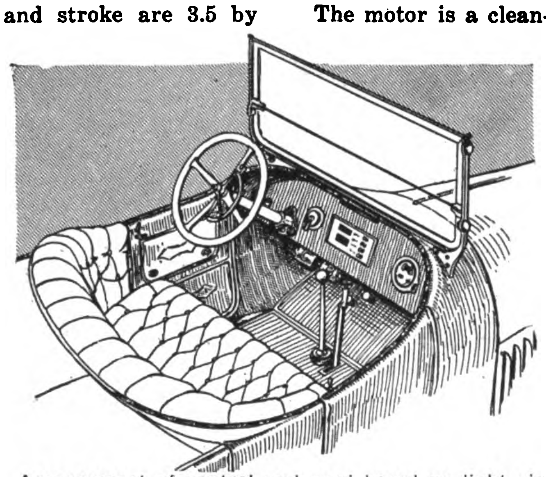
FOR 1915 the feature of the Haynes line will be a new model light six of 55 horsepower, weighing 2,950 pounds, and selling for $1,485, fully equipped. The wheelbase is 121 inches. It will be furnished in both two and five-passenger body styles, and will have left drive and center control. The vacuum system of gasoline feed has been adopted, but the electric method of gearshifting will not be used on this model. A unit power plant with the cylinders cast in a block is used. The bore and stroke are 3.5 by 5 inches.

In addition, the Haynes Automobile Co., Kokomo, Ind., is offering a big six rated at 65 horsepower and selling for $2,250, and a four developing 48 horsepower and selling for $1,660. The electric gearshift will be fitted to these two models at an additional price.

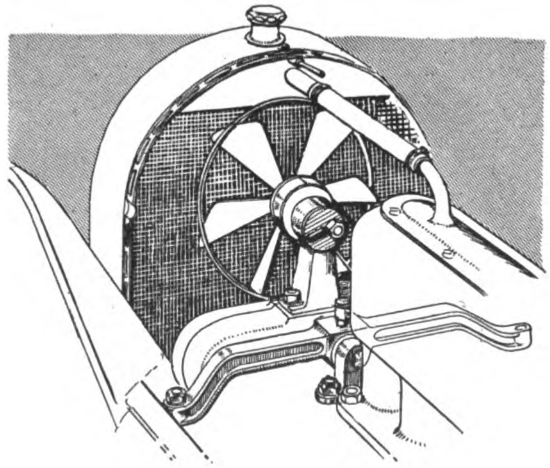
Light Six Entirely New

There are many features of interest in the new six, which is an entirely new job from headlights to spare tire. Smooth body lines are noticeable. The radiator has rounding edges, and the hood tapers slightly to the cowl, where the slant almost imperceptibly increases until the windshield and door panels are reached. The sides of the body sweep down gracefully from the foot of the windshield, the sides being practically horizontal from the center of the front door to the rear of the car. A modern feature is seen in the absence of upholstery on the top edges of the body sides, these being topped off by strips of polished wood. A rakish appearance is produced by the long, straight body lines and the low suspension that is obtained by slinging the springs under the axles.

Unusually complete equipment is a feature. This comprises a motor-driven tire pump, Firestone demountable rims, including one extra rim, and the tire carrier already mentioned. A ventilating clear and rain-vision windshield built into the cowl is part of the outfit, as well as a one-man top, with a Neverleak cover and Collins quick-adjusting curtains. There is an electric horn under the hood, operated by a button on the steering wheel. The headlights are provided with a dimming attachment for city driving. Robe and foot rails are found in the tonneau, and there is a full tool equipment.



Arrangement of control and cowl board on light six showing the flush mounting of the ignition switch, lighting control switches, and speedometer



Front motor support and fan construction on new six. It will be noted that the front of the motor is hung at just one point. The fan is adjusted by the eccentric bushing shown

The motor is a clean-cut design, rigid and compact in construction. The valves are inclosed. Cooling is by means of a cellular radiator, pressed steel fan and large centrifugal water pump. Lubrication is supplied by a combination splash and force-feed system. A plunger pump circulates oil through the motor at the rate of one-half gallon per minute. The connecting-rod dip pins splash the oil from the troughs, which are filled by the pump.

A Rayfield carbureter with hot-air connection to the exhaust pipe is employed, and the intake manifold is cast integrally with the cylinders, so that, not only is the exterior of the motor simplified, but carburetion is aided by the heating of the charge in the inclosed manifold.

Carbureter Under Constant Pressure

The carbureter is fed directly by gravity from an auxiliary tank situated on the dash. Fuel is automatically drawn into this tank from the main tank in the rear by means of the suction of the motor, the auxiliary tank being connected to the manifold by means of a small pipe. Since the amount of fuel in the tank is always the same, the gasoline is fed to the carbureter at a uniform pressure, whether the car is moving along the level, up or down hill.

Separate units, of Leece-Neville make, are used for starting and lighting. Both are dust-proof. Ignition is supplied from the main storage battery through a Remy combination circuit breaker and distributer. The intensity of the spark is independent of the speed, and this is a great advantage in starting.

From the motor the power is transmitted through a positive three-plate, dry-disk clutch which is lined with Raybestos. It is mounted on ball bearings, is completely incased, yet is easily adjusted from the outside. It is smooth and effective and easy to operate.

The gearset is a three-speed, selective sliding type. The gears are manufactured from drop-forged Samson steel, heat treated, while the shafts are also made of this material, and are mounted on imported ball bearings of ample proportions.

Semi-elliptic springs are used all around. They are made of high-quality spring steel, oil tempered. The front springs are 38 inches long by 2 inches wide, and the rear 54 by 2 inches.

The rear axle is a special Haynes floating type. Unusually large bearings are used throughout, it is stated. Nickel steel is used as a gear material, and the double internal brakes are 14 inches in diameter.

The rear end of the Haynes light six frame is arched in order that an extremely long semi-elliptic spring may be used. Such a construction gives a number of distinct advantages. The length of these springs is 54 inches, giving a very easy riding car.

The gasoline tank is carried between the frame members in the rear, and directly back of it is the carrier for spare tires.

Left drive with center control has been adopted, and all the instruments are neatly arranged on the cowl board and within easy reach of the driver.

The light six is known as model 30. In addition, there will be the big six, developing 65 brake horsepower and selling for $2,250. This car is known as model 31 and has a wheelbase of 130 inches. Model 32 is the designation of the Haynes four, which gives a maximum of 48 horsepower, has a wheelbase of 118 inches and sells for $1,660. Closed bodies are built on these two chassis. The big six is furnished with a seven-passenger limousine, selling at $3,650 and with a four-passenger coupe at $3,000. A coupe body seating four passengers is fitted to the four. This sells for $2,500.

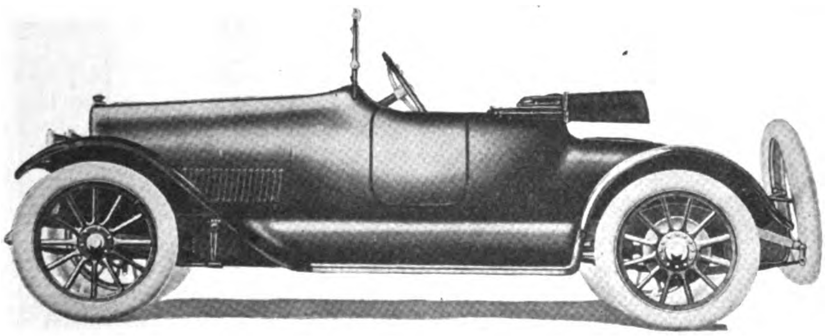
Russia—An Opportunity

(*Continued from page* 445)

prise rests upon the treatment given to its customers. A poor shop could not exist in Russia, because no high-grade machine will be left for repairs there and no fortune can be made by repairing cheaply the cheap machines only. In reliable places the charges are quite high, considering the average wages paid to the workingmen, but they are lower than in the United States, being about 40 cents an hour. In a few instances the agencies have no repair shop in the true sense of this word, because they try to get along by making the necessary quick repairs and sometimes quite complicated replacements, such as changing crankshafts, right in the yard of their location, under the open sky. An arrangement like that is feasible only with the cheapest cars, when the customers are not very exacting, and it is explained by the difficulty to get a space for a suitable show-room and garage with shop in connection with it. The available places in old houses are not arranged for that, and one has to build to obtain it. Naturally, then, one tries to do the work in the open, when a customer drives up for a short job on his car. As in this country, the general garage business is frequently associated with the renting of cars, sometimes as a taxicab company. The owner is almost always obliged to rent space for his car in a public garage, as the living houses do not offer any accommodations for them, except when specially so arranged by the owner himself. Rent is about $8 per month and as one has a chauffeur, no inconvenience is felt from having the cars housed at some distance from one's residence.



New Haynes light six with two-passenger body

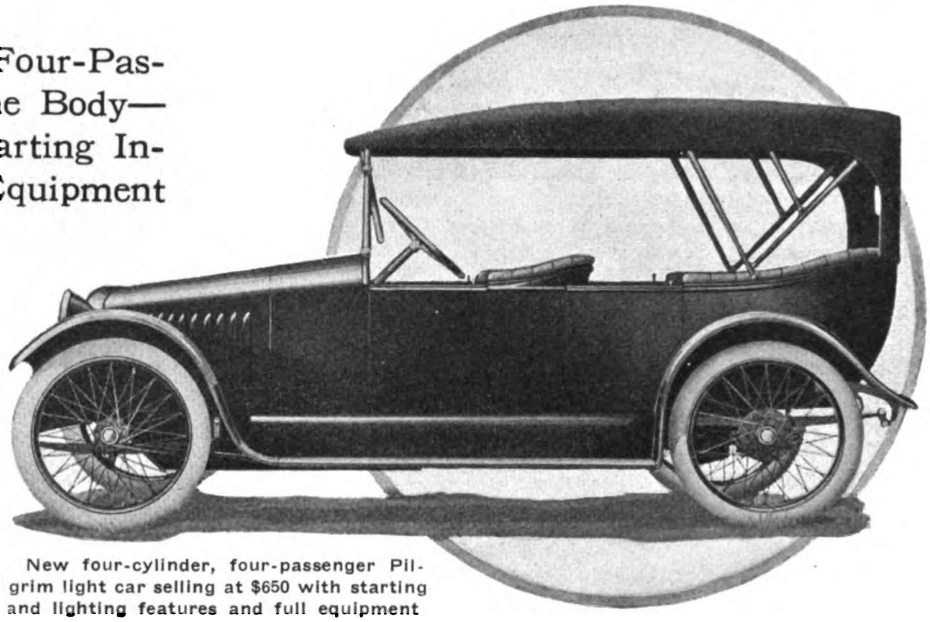
Personal element of the dealer naturally plays a great role in the matter of sales. It is remarkable how in Russia certain makes of cars are distributed in sections, one being the biggest seller in Moscow, another one in Kief (Kiev), being machines of equal standing.

Some cars have changed representatives before finding one who is giving satisfaction. The proper selection of agents is obviously very important for the business, and one can name a few makes of cars which did not get due favor at first but which are gradually spreading now chiefly due to the efforts of their present agents.

THE END.

Pilgrim Light Car to Sell for $650

New Car Has Four-Passenger Streamline Body—Lighting and Starting Included in Full Equipment



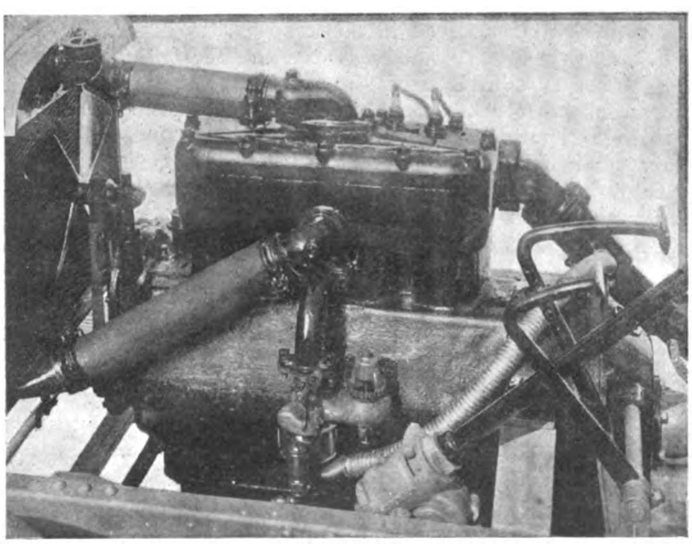
New four-cylinder, four-passenger Pilgrim light car selling at $650 with starting and lighting features and full equipment

DETROIT'S latest light car is the Pilgrim, designed by W. H. Radford, former chief engineer of the Warren Motor Car Co., and previous to that connected with the engineering departments of the Olds Motor Works and the Hudson Motor Car Co. Some time ago it was announced that Mr. Radford was at work upon a light motor vehicle, but THE AUTOMOBILE is now able to give complete details of this machine, which, with full equipment, including lighting and starting features, is to sell for $650 with four-passenger streamline body.

The Pilgrim Motor Car Co., which is laying its plans to manufacture in Detroit, is said to be amply financed by eastern capital, all of which is subscribed, the company being a close corporation. The factory has been located, material contracts are being let and dealers are contracting for territory, according to advices received from the new concern.

Deliveries are to commence on December first, and well-known standard units are incorporated in the design. Mr. Radford has had the first car on the road for some time, having driven it over some 3,000 miles so far.

Though the Pilgrim is a light car and weighs but 1,300 pounds fully equipped, it is amply roomy for four passengers on the wheelbase of 100 inches. Tread is standard at 56 inches, and the body is constructed of sheet steel, has 18-inch doors and 28 inches of leg room in both forward and rear compartments. The fenders, which are domed, conform closely to the wheels and bring the design strictly up to the minute. The fenders and running boards are 9 inches wide, the running board having a length of 57 inches. These parts are made of pressed steel.



Left side of four-cylinder block-cast motor used in new Pilgrim light car. Note the location of the radiator filler cap on water outlet pipe under the hood. Also note hot air intake for carbureter

Wheels are of demountable wire type and carry 30 by 3-inch tires on interchangeable clincher rims. The gasoline tank is also placed in accordance with present-day dictates under the cowl and has a capacity of 8 gallons.

The motor is an efficient appearing four-cylinder water-cooled type of 3⅛ inches bore and 4 inches stroke, block cast, with all valves on the right side and completely inclosed. This cylinder diameter gives the engine a rating of 15.6 horsepower, according to the S. A. E. formula, but it has developed considerably more than that. Valves, of conventional type, are 1⅛ inches in diameter and have adjustable push rods.

The motor does not combine the gearbox in unit with it, but rather that part is combined with the rear axle. At the same time, the power plant is three-point suspended and the flywheel inclosed.

Manifolds are a little out of the ordinary in that the cast exhaust manifold alone occupies the right side, bolting to the cylinder casting and having an opening to each exhaust port, while the intake passages are cored within the cylinder block itself and pass from the opposite side, where the Schebler carbureter is placed with but a single external opening from the casting to the vertical pipe from this carbureter.

The cylinder head is removable and bolts rigidly in place. It goes over the entire top of the casting and when removed exposes valves, water jackets and cylinders. This is a commendable feature of present-day motor design.

The working parts of the motor are all substantially made of conventional type. There are three main crankshaft bearings. These measure 1¾ inches in length for the front end crankpins and 3 inches for the other two. Pistons are each fitted with three rings, and the camshaft has its cams forged integral. Gears at the front end drive it, as well as the lighting generator.

Cooling is by thermo-syphon, employing a 12-inch fan, belt-driven. The radiator is a McCord vertical tube type with horizontal fins. The core has four rows of ¼-inch tubes. Ignition is taken care of by Connecticut distributer in connection with a Willard storage battery rated at 6 volts and 35 amperes.

This battery is also used with the lighting system and for cranking purposes. The Auto-Lite generator, located on the right side of the motor has the ignition distributer in unit with it, and serves for charging the battery. The starting unit has not definitely been decided upon, but it will utilize this same battery current for turning the crankshaft.

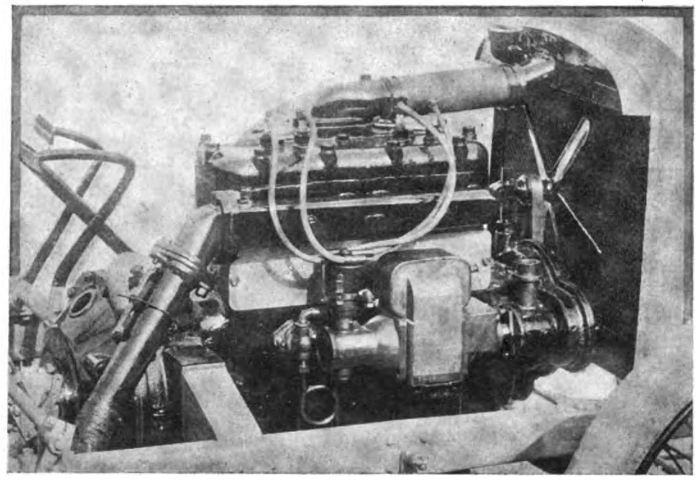
The drive back from the motor is through a cone clutch, leather faced, and a conventional form of driveshaft inclosed with a neatly designed torsion tube which is fitted with a Spicer double universal joint at the front end. In accordance with usual practice when the gearbox forms a unit with the rear axle, this box is inter-positioned between the tube and the axle housing, bolting to each through flange construction. The gearset is of the Northern Engineering Co.'s special design and gives three forward and reverse speeds. It utilizes Hyatt roller bearings, and the drive shaft is four-splined, insuring strength. The countershaft is mounted below the main shaft, and thus gets good lubrication.

The rear axle is semi-floating and has Hyatt bearings also. The drive is through bevel gears with a ratio of 4 to 1, while the propeller shaft and driveshafts are all of chome-nickel steel having a diameter of 1 inch. Due to the torsion tube and its diagonal brace rods all torsional strain and drive strain are carried to the forward cross member of the frame through the yoke at the front end of the tube. The brakes are external and internal, operate on the hubs and use 8-inch drums.

Spring suspension is standard in every way. The 30-inch front half-elliptics are overhung on the axle, as are the 40-inch rear three-quarter elliptics. All leaves have a width of 1½ inches, and, due to their length, these springs should be conducive to very easy riding. The frame is of pressed steel, having a channel 3 inches deep and a 3-inch kick-up at the rear over the axle. The top of the frame is 18 inches from the ground, and there are the usual cross members.

Steering is on the left and control in the center. There are no levers on the wheel, the accelerator pedal being so arranged that it can be either used in a fixed position or as the ordinary accelerator. The spark advance is on the dash. The steering gear is of the worm-and-wheel type, fore and aft, and the wheel has a diameter of 18 inches.

Standard equipment, in addition to that already mentioned, includes one-man top, top envelop, storm curtains, windshield, speedometer and electric horn and tools. The car is really ready for the road when purchased, it is pointed out.



Right side of four-cylinder motor used in Pilgrim light car. Note mounting of starting and lighting unit. Also single exterior manifold, the intake passages being cored within the cylinder block

Low's Small High-Pressure Motor

(*Continued from page* 453)

a flexibility to the power output which can be compared only to that of a steam engine. Until lately the design of this valve constituted the principal difficulty in the construction, as it was exposed to very high temperatures. It has now in fact been replaced by a slide valve.

As soon as the motor works with full compression the ignition by magneto might be switched off, but it has been found that the greatest economy and the smoothest operation is secured by introducing the vapor gradually and maintaining the ignition by magneto throughout the explosion stroke. In this manner the expansion curve of a Diesel motor is obtained. Only the combustion chamber is watercooled.

[The report dwells further upon the claimed and very extraordinary economy of the motor and its very high power combined with small weight, but, as the mechanical description remains very fragmentary, all the statements should probably be accepted with much reserve.—Ed.]—From *Auto-Technik*, July 4.

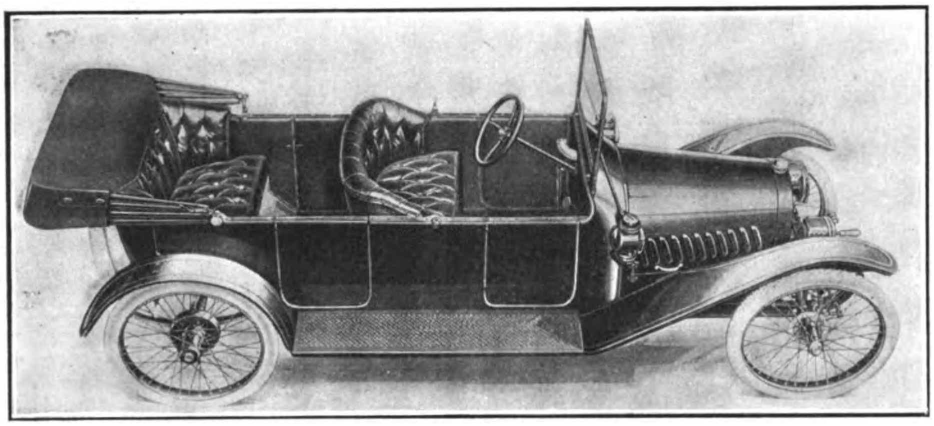
New Woods Follows Big Car Practice



New Woods Mobilette showing tapering hood and streamline body

Sells for $380—Tandem Seating Continued—Streamline Body—Four-Cylinder Motor and Sliding Gearset

AN entirely new car has been announced by the International Cyclecar and Accessories Company, Chicago, as its product for 1915, this car to be known as the Woods Mobilette, model 3. It is featured by a four-cylinder water-cooled motor, body with tandem seating, 36-in. tread and selective gearset, and its price has been set at $380. The general appearance has been changed so as to make it entirely different, having long running boards, tapering hood, cowl fuel tank, streamline body and as an added feature under-overslung pressed steel frame.

The motor has a bore and stroke of 2½ by 3½ inches and is of L-head construction with the valve mechanism inclosed. The cylinder and upper half of type crankcase are cast as a unit, and the cylinder head is bolted to the top of the casting. The left side of the engine is clean except for the water inlet pipe. On the right side is the magneto, carbureter and oil pump. Cooling is by thermo-syphon system. The engine is suspended by three points from a pressed-steel frame which is of the under-over type. In this the front portion is suspended under the axle and the rear portion over the axle.

From the motor the power is taken by a leather-faced cone clutch with spring inserts and thence by shaft to a two-speed selective gearset incorporated with the rear axle. This is of the floating type. The rear springs are elliptic and underslung, while the front are semi-elliptic and hung above the axle. Propulsion is through the springs and torsion tube which surround the propeller shaft.

Wire wheels of 28 by 2¾ inches are regular equipment. The body is of sheet metal and accommodates two persons sitting tandem. The car's wheelbase is 102 inches and the tread 36 inches. Equipment at $380 includes two side oil lamps, taillight and set of tools, and added equipment, including top and windshield, is $15 extra. The body is interchangeable with a commercial body.

How to Go from Missoula to Spokane

For the information of automobile tourists who contemplate making a trip from Missoula, Mont., west to Spokane, or through Washington and Idaho points, George R. Metlem, secretary of the Montana Highway Commission, has secured the following data regarding road conditions now prevailing in the western part of Montana.

Of the main state roads leading west from Missoula the tourist has the option of three outlets to the states of Idaho and Washington, first, by way of St. Regis, to Wallace, Idaho; second, by way of Ravalli Plains, Thompson Falls to Spokane, Wash.; third, by way of Ravalli, Polson, Kalispell, Libby and Troy to Spokane, Wash.

It is true the grade just west of St. Regis is rather steep, but a new grade is being constructed, the work being in progress at this time, and when completed it will not exceed a 10 per cent. minimum at any place. At present cars that are unable to pull the old grade will be taken over without any charge by the teams working on the new grade.

Tourists taking this route will do well to replenish their gasoline supply at St. Regis in order that they may have a full tank for the grades.

The roads west of Wallace to Spokane, are in good condition. Leaving Missoula on the route by way of Thompson Falls, a good road has been constructed from Missoula to Ravalli and from that point the road leads down to Clark's Fork River. The best road from that point to Spokane follows the line of the Northern Pacific Railway, and is also in splendid condition.

The third route, leaving Missoula west by way of Ravalli over the Flathead Indian reservation to the foot of Flathead Lake at Polson. Here the tourist should take the west side lake shore route via Dayton. This road is open to traffic at all seasons, and leads to Kalispell. From Kalispell west the outlet is over the old line of the Great Northern Railway to Marion and Jennings thence through Kootenai Canyon to Libby.

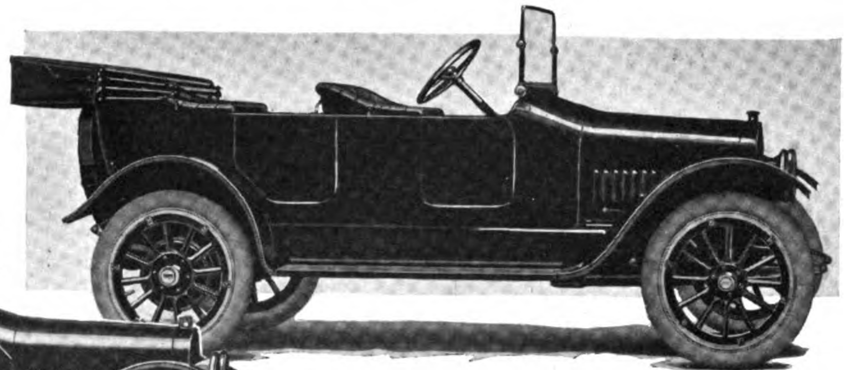
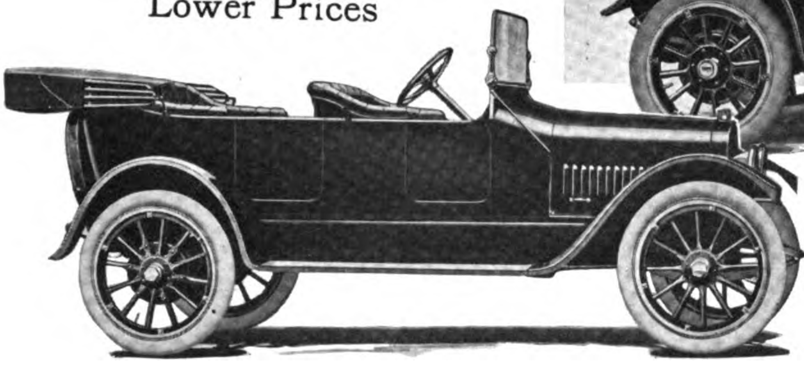
Two New Jacksons for 1915

New Streamline Four and Six Replace Former Three Models—Greatly Increased Values for Lower Prices





Above—Jackson Olympic 46 four-cylinder five-passenger touring car, which sells for $1,375, with complete equipment, or $10 less than the smaller four of 1914

At left—New Jackson 48 Six touring car, which sells for $1,650, a reduction of from $500 to $650, as compared with the corresponding five and seven-passenger models for 1914

THE big plant of the Jackson Automobile Co., Jackson, Mich., will be devoted to the production of only two models for 1915, instead of dividing its efforts between three types as in 1914. The new models are, quite naturally, a four and a six, and they are both of the trim, streamline design so much in vogue today.

Last season's Olympic small four, Majestic larger four and Sultanic six have really disappeared, and their places are filled by the 48 Six and the Olympic 46. The latter is mechanically somewhat similar to last year's Majestic, having about the same motor as that model used.

More Value for Less Money

Thus, not only is the four-cylinder Jackson of 1915 a more powerful car than that which carried the name Olympic last year, but it is also offered at a lower price—$1,375 with all equipment, as compared with $1,385 last season. This really is not a fair price comparison, for with nearly the same mechanical chassis features as the larger four of last year and with the same motor, it should be compared with that model in price. On this basis, the reduction has been very great, the 1914 Majestic listing at $1,885. The cut is therefore really $510.

The new Jackson six is also a much less expensive car than was the 1914 six. The price of the 48-Six is $1,650, as compared with the figures of $2,300 and $2,150 asked for the seven and five-passenger models, respectively, last year. This is a reduction of from $500 to $650. The new six is a lighter vehicle than its predecessor, but equally efficient and dependable.

Both Models Are New

Because the two new Jacksons are really not continuations of any previous models, it is hard to draw comparisons with former constructions. Nothing has been neglected to bring the cars up to the latest demands of the motorwise public and in appearance as well as mechanically they are in the front rank. They have the latest of appointments, smooth-sided bodies, clean running boards, hoods sloping gracefully into cowls and sloping bonnets which carry out the general lines.

As compared with the four-cylinder Olympic model of 1914, the new car bearing this title has a longer wheelbase, being increased by 2 inches to 117 inches, while the motor has fully 5 horsepower more, its rating by the maker being about 45 horsepower. This is largely due to the use of the 4½ by 5¼-inch motor in place of the 4⅛ by 4¾-inch type formerly used. The cylinders are cast in pairs and the unit power plant construction of three point suspended type is employed. All valves are on the left and inclosed by cover plates.

334 Cubic Inches Displacement

The cylinder dimensions give a stroke bore ratio of 1.17 to 1, and a displacement of 334 cubic inches. With its bore of 4½ inches, the A. L. A. M. formula accords it a rating of 32.4 horsepower. This naturally falls much below the true power of which the engine is capable.

Working parts are all well designed and aid in this power development. The crankshaft and camshaft, both of which are of drop forged steel, are supported by three main bearings each. Connecting-rods are also steel forgings, while pistons and cylinders are constructed of gray iron. Steel tubing is used for the making of the wristpins within the pistons. Valves are rather large and thus do their part to increase the power, their diameter being 2 1/32 inch. They are of tungsten steel and interchangeable. The pistons have three rings each.

Timing gears, housed at the front, are drop forged steel and iron, this combination being used to make them more silent, as steel running against iron is less noisy than iron against iron or steel against steel. These gears drive the camshaft and magneto shaft in the usual way.

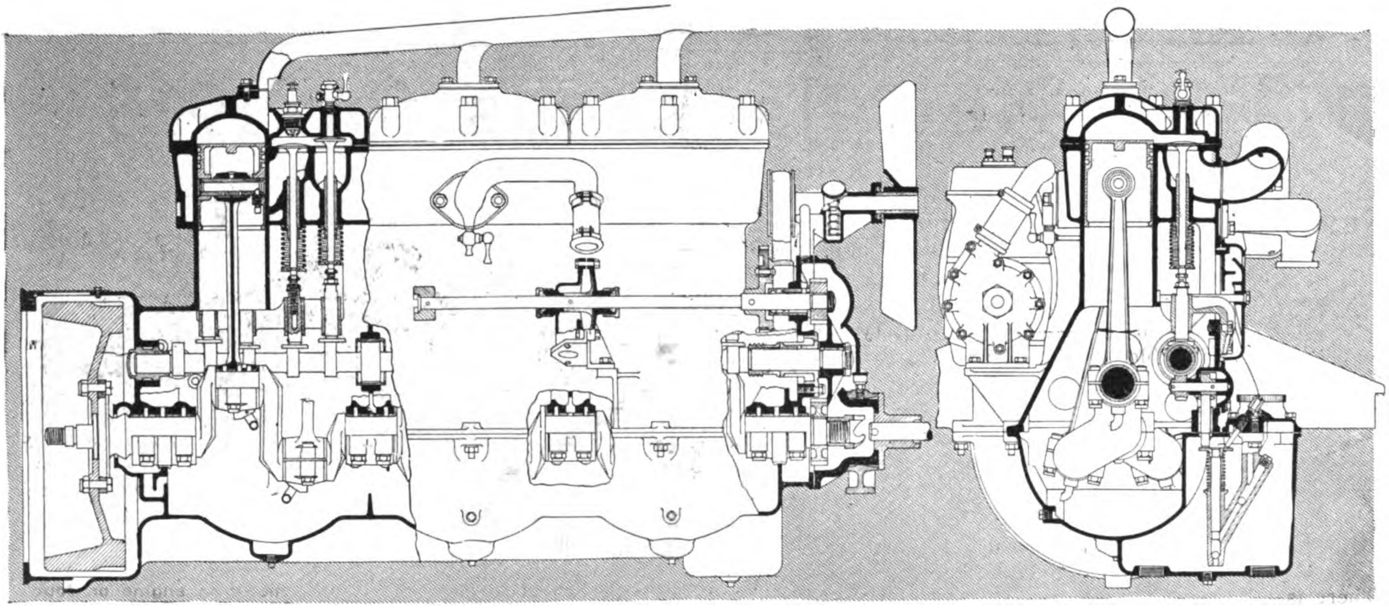
Some of the motor dimensions are given:

Crankshaft { Front bearing—1 7-8 by 3 7-16 inches.
Center bearing—2 inches diameter.
Rear bearing—2 1-8 by 4 1-2 inches.

Camshaft { Front bearing—1 by 1 27-32 inch.
Center bearing—1 by 2 1-8 inches.
Rear bearing—1 by 1 9-15 inch.

Connecting rod bearings—2 by 2 3-4 inches.
Piston pin bearings—1 1-4 by 2 9-16 inches.
Length of pistons—6 1-16 inches.
Length of connecting rods—10 inches.
Valves { Diameter—2 1-32 inches.
Length stem guides—3 13-16 inches.

Piston pin bearings are constructed of phosphor bronze



Left—Part sectional view of unit power plant used in the new Jackson 48 Six. Right—Front section through same motor

while connecting-rod and crankshaft bearings are made of die cast babbitt.

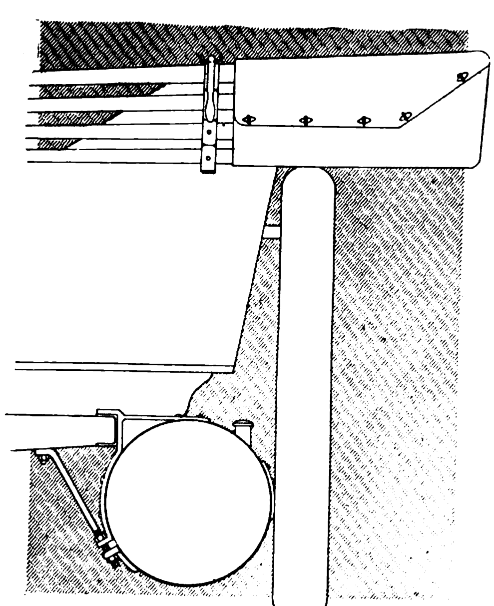
Force-Feed and Splash Oiling

The cooling system of this engine is of the positive type employing a centrifugal pump driven from a shaft on the right side. Back of the pump is the magneto and driven by the same shaft. Oiling is maintained by a force-feed and splash arrangement of conventional form. The oil is pumped from the reservoir at the bottom to the bearings and into the troughs from which it is splashed by the moving rod ends up into the cylinders and to the various other surfaces.

Auto-Lite Electrical System

As heretofore on its four-cylinder cars, the Jackson company uses Auto-Lite cranking and lighting on this car. The cranking motor is mounted in a rather unusual position at the forward end of the engine, as last year, and drives through an inclosed chain and ratchet construction. This electric motor really rests upon its end, its armature shaft being vertical instead of horizontal. The armature shaft carries a spiral gear which drives a sprocket on a countershaft through engagement with a gear on this shaft. The sprocket in turn connects with a sprocket on the crankshaft which sprocket carries one member of a ratchet clutch. When the starting switch is thrown in, the other sprocket member, which slides on the splined starting shaft, is mechanically brought into engagement with the sprocket member of the clutch, and the crankshaft is rotated.

The generator is placed on the right side of the engine on a bracket. It is driven also by a silent chain, and runs at a speed 2.5 times that of the crankshaft. The cranking speed is about 100 revolutions a minute. The system works at 6 volts, and there is a centrifugal governor to prevent overcharging of the battery or too high rate of charge due to high engine speeds. A Willard 120 ampere-hour storage battery placed under the rear floorboards is a part of the electrical system. In connection with the lighting arrangements, a dash lamp has been added, which is a refinement to be appreciated.



Rigid mounting of tire carriers to gasoline tank straps at the bottom and to an iron running within the body piece at the top on the new Jackson cars

Cone Clutch Is Continued

As already brought out, the gearset is an unit with the engine, and gets its power through the intermediary of a leather-faced cone clutch. There are three speeds forward and reverse, and the main shaft and jackshaft are carried on ball bearings. These shafts have a diameter of 1¼ inch.

Back of the gearbox, there is a universal joint, after which the drive shaft enters a torsion tube bolting through a flange construction to the rear axle housing, in accordance with conventional practice for such design. The axle used is a floating type made by Salisbury. It has a pressed steel housing, and Hyatt bearings are used in the differential and wheels. Thrust is taken by ball thrust bearings.

As with other Jackson designs, the new four uses elliptic springs both front and rear. This construction makes very easy riding, it is pointed out.

One change which marks a tendency of the times is the adoption of center gearshaft and emergency brake levers instead of the left position heretofore used. Drive continues on the left.

Although a cowl gasoline tank was incorporated on the fours last year, this has been removed entirely, and a vacuum system with tank at the rear has been adopted. The Webb-Jay type of vacuum device for lifting the gasoline automatically to the tank portion of the outfit on the back of the dash is used. From this small reservoir, it feeds by gravity to the carbureter.

Other minor changes are the adoption of much more rigid tire carriers at the rear which hold the spare casings without vibration. A rigid iron at the top runs through the rear portion of the body to the framework, while the lower supports are attached to the tank.

Tires are 34 by 4 inches, and as an added feature of equipment the rears are of the non-skid variety. A Brewster green finish has been adopted which is very attractive.

A three-passenger roadster is also offered on the four-cylinder chassis at the same price as that specified for the touring car type.

Although very similar to the four-cylinder Jackson in outward appearance, the new six is somewhat different mechanically. Built upon a wheelbase of 125 inches, this car still has all of the Jackson earmarks, however.

The motor is a 3½ by 5-inch Northway which develops the horsepower indicated by the model designation—48. Due to the small bore, the A. L. A. M. rating is low—29.4—but since the stroke is nearly twice the bore as shown by the ratio of 1.43, this large difference is readily understood. The piston displacement is 288.5 cubic inches.

The design is an L-head unit power plant type with the cylinders cast in one block. Valves are all on the left side, and the upper half of the crankcase is in unit with the cylinder casting, making a compact construction. There are three separate cylinder heads in this engine, each covering two cylinders. When removed these plates or cylinder heads expose the pistons and valve heads which is of great advantage. Heat-treated alloy steel bolts securely fasten the head pieces to the casting proper, and interposed between the two parts is a copper gasket, making a tight joint.

There is no departure from Northway standard design in this power plant. The lower part of the crankcase takes care of the oil reservoir, and at the front the spiral timing gears are completely housed. The centrifugal water pump is driven by shaft on the right side, and back of it is the Delco combination unit which will be spoken of more in detail later. The flywheel is completely inclosed, and at either side of its housing there is a crankcase arm integrally cast for supporting the unit. The front support is at the center of the front end.

Lightweight Reciprocating Parts

The moving parts are all constructed of recognized standard parts. Drop forged connecting-rods, camshafts and crankshafts are made as light as possible consistent with strength and their bearings are all of ample size. The crankshaft and camshaft are each carried on three bearings.

Some of the dimensions follow:

Crankshaft	Front bearing—1 5-8 by 3 7-32 inches.
	Center bearing—1 7-8 by 2 19-32 inches.
	Rear bearing—1 15-16 by 3 7-16 inches.
Camshaft	Front bearing—1 1-8 by 2 inches.
	Center bearing—2 1-8 by 1 inch.
	Rear bearing—1 by 1 3-4 inch.

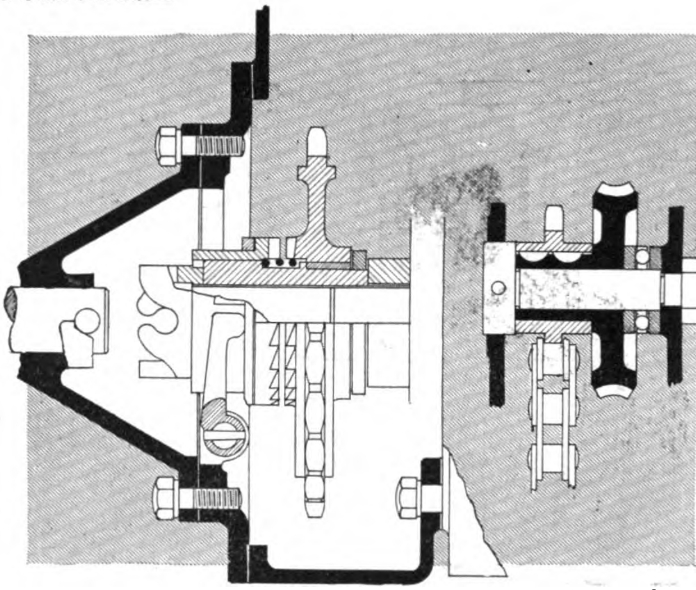
Connecting rod bearing—1 5-8 by 2 1-4 inches.
Piston pin bearing—7-8 by 1 7-8 inch.
Piston length—4 1-2 inches.
Connecting rod length—10 3-8 inches.
Valve diameter—1 23-32 inch.
Valve lift—5-16 inch.
Flywheel diameter—14 inches.

The oiling system of this engine is of the constant level splash type, and the reservoir is located on the left front side of the oil pan. A plunger pump operated by the camshaft pumps the lubricant to the crankcase, after which it runs from trough to trough, and the cylinder walls and other parts get it by the connecting-rod splash.

Delco Motor-Generator Unit

The standard Delco motor-generator unit is employed. This also takes care of the ignition through the use of a distributer. The unit is driven off the end of the pump shaft on the right rear side of the engine. Its gears mesh with those of the flywheel for starting purposes in the usual way, while when these are out of mesh, it drives from the pump shaft as a generator. It uses a Willard storage battery located under the rear floor boards as does the other car, and current from this is sent to the unit for cranking purposes when the motor-generator is temporarily operating as a motor.

Like the four, the new six uses a cone clutch and three speed gearset. The shafts and gears are of alloy steel and properly mounted on their bearing. Drive to the rear is through an open propeller shaft which is fitted with two universal joints, one at either end. A torsion member parallels the shaft and takes the drive. The rear axle is also a Salisbury floating type and is fitted with Hyatt roller and annular ball bearings.



Ratchet clutch attachment of cranking motor to engine on four-cylinder 1915 Jackson model

Like the four, the spring suspension is characteristically Jackson due to the use of elliptics all around. The frame is dropped to bring the car close to the ground.

Unlike the four, the six has its gasoline tank under the cowl with gravity feed to the carbureter. There is a supply tank at the rear, however.

Tires are 36 by 4 inches and non-skids are used in the rear. Dark blue is the standard body color.

The Call of Mars

(*Continued from page* 437)

Hundreds of military automobiles were to be found on the road to the east of Brussels; these were taking ammunition and food to the main forces. The Belgians have not the same system as the French, and do not possess any subsidized motor lorries, but they have pressed into service every type of car and hundreds of private touring cars are engaged in transporting food. Near Diest and at the village of Haelen the results of actual fighting were to be seen. The previous day the German advance forces had attacked these two places, but had finally been driven off with loss. Dead soldiers were still lying on the roadside and in the fields. A very large number of dead German horses were lying around, many of them disembowled and causing a stench noticeable a mile away. Peasants were digging trenches into which the carcasses were dragged. If the legs protruded they were chopped off; a thin covering of earth was thrown over the dead animals. The village schoolhouse had been transformed into a hospital. As it could not hold all the wounded some of the German soldiers were put on mattresses under trees in the village street and were tended by the peasants.

After a Cavalry Charge

On one of the main, straight granite-paved roads a cavalry charge had been ordered. Belgian troops were in hiding behind the hedges and were fortified at the bottom of the road. At frequent intervals dead horses lay by the roadside, and at the bottom of the road they were piled up in a solid mass. Several of the German officers killed in this fight, and whose bodies still could be seen, had their pockets filled with gold.

Continental Develops High Speed Motor

New Light Engine Follows Foreign Practice of Long Stroke and High Piston Speed

TO meet the demand for a small, high-speed, small-car motor, the Continental Motor Mfg. Co., Detroit, has lifted the curtain from its newest model which is the result of careful study of conditions both here and abroad.

This new Continental is the smallest motor which has emanated from the plant. The motor, designated Model U, is the same motor as contracted for by Morris-Oxford, Ltd., London, England. This English small car manufacturer placed its contract some months ago. Quantity production will be started the first of the year, and samples supplied in November or December.

It is a unit-power-plant type, adapted for any one of the standard makes of clutch and gearset units on the market. The cylinders, cast in a block, measure 2 3-4 by 4 inches. These dimensions give a S. A. E. horsepower rating of 12.1. On brake test the motor has about shown from 15 to 18 horsepower.

Outwardly the new motor has a distinctive appearance, in that the upper half of the crankcase is integral with the cylinder casting. The cylinder head is removable and is held down by steel bolts and allows for the exposing of all the valves, pistons and cylinders. The other main unit is the lower half of the crankcase which carries the oil pan. The motor is arranged for four-point support, integral arms extending outward for attachment to the side rails of a chassis, being a part of the cylinder block casting.

The valves are on the left together with the exhaust manifold, while the carbureter opening is on the right. A cored passage extends across within the cylinder block to the valve side where the gases are distributed internally to the four cylinders.

The magneto drive is transverse at the front end, there being a spiral gear mechanism driving the cross shaft to which the magneto is attached, it being carried on a bracket cast integrally with the cylinder block. Just ahead of the magneto and its drive, the fan is mounted and is driven by a belt. This arrangement of magneto and carbureter leaves the sides of the motor free from any complications, and accessibility is thereby gained. The lower half of the crankcase carries at its forward end the complete starting crank assembly, including the crank.

Thermo-syphon cooling is employed and in casting the cylinders and crankcase as a unit, the waterjackets are carried the full length of the cylinder bore. Large water connections also do their part.

The lubrication is in accordance with Continental practice, being a combined force feed and splash system whereby the oil pump supplies the individual trough under the cylinder maintaining a constant lever of oil in them. The ends of the connecting-rod dip into these troughs.

The moving parts are all of standard construction and in accord with Continental practice. The pistons have three rings each, and the crankshaft is carried on three bearings and the camshaft on two. The valves have standard form of tappet construction and adjustment.

The weight of the motor including the flywheel and regular equipment is 210 pounds.

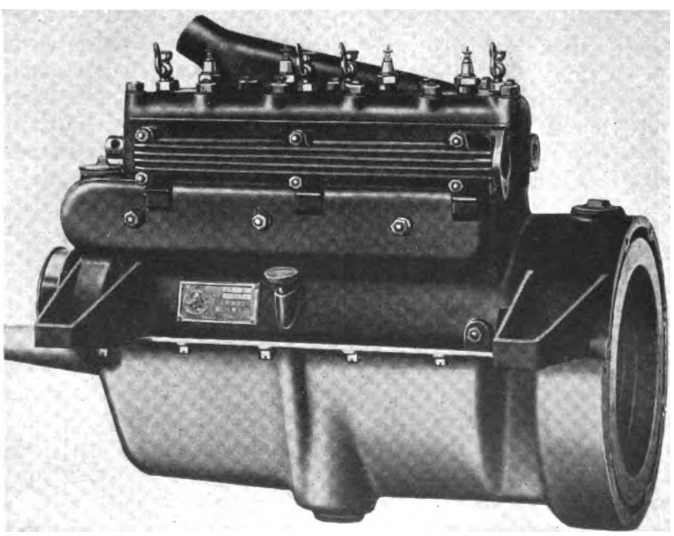
The principal specifications and dimensions are given below. Where two dimensions are given the first refers to the diameter and the second to the length.

	Inches	Millimeters
Camshaft diameter	1	25
Camshaft bearing, front	2x1 3-4	51x44
Camshaft bearing, rear	1 15-16x1 1-2	49x38
Connecting rod, length	7 1-2	191
Connecting rod bearing	1 3-8x1 1-2	35x38
Crankshaft bearing, front	1 1-2x2	38x51
Crankshaft bearing, middle	1 1-2x1 5-8	38x41
Crankshaft bearing, rear	1 1-2x2 7-16	38x62
Crankshaft extension	As ordered	
Piston length	3 1-8	79
Piston pin bearing	5-8x1 13-32	16x36
Piston rings (three in number), width	3-16	5
Valve diameter	1 1-2	38
Valve stem diameter	3-8	9
Valve lift	5-16	8
From supporting arm face down to center of crank shaft	1 1-2	38
From center to center of supporting arm bolts	20	508

A. C. A. Increases Its Laboratory Facilities

NEW YORK CITY, Sept. 1—The Automobile Club of America has increased its laboratory facilities considerably by moving the laboratory to a new position in the Club building, offering a greatly increased floor space. In line with the policy of the club to give efficient laboratory service to commercial concerns, a new dynamometer will be installed on which tests on the entire chassis may be carried out. This will be one of the Diehl rear wheel plants, in all probability.

Herbert Chase, who was recently appointed to the position of chief engineer of the club, has organized an efficiency scheme by means of which the cars of the club members are kept up to their highest standard. Mr. Chase's former position of Laboratory Engineer is now filled by Ferdinand Jehle, who was formerly engineer of the Commercial Engineering Laboratory, Detroit, Mich.



Valve side of the new Continental—the intake enters by means of a cored passage across the cylinder

War Should Increase Automobile Exports

Great Demand for Cars Among Warring Nations — South American and Colonial Trades Must Be Supplied by the United States

THE bearing of the war situation on the automobile industry has so many phases that it is impossible to trace the actual result on business as a whole, except to state that, taking the consensus of opinion, it cannot result except for good in this country.

Little is exported from the territory already affected by strife to the United States, and yet the little town of Liége, which was the scene of the first serious clash, is noted for its automobile and accessory productions. Here the Minerva cars and F. N. automobiles and motorcycles are manufactured and here is located the factory of the Englebert tires, one of the makes used to some extent in America.

Liége is but a single example. Throughout the entire country now overrun by the soldiery of Europe are industries closely allied to that of the manufacture of automobiles. The mines and steel works have abandoned their activities, and motor vehicles are being destroyed as rapidly as they were formerly manufactured.

Every Car in Use

The increase in the demand for horses which has always been the natural outcome of previous wars will naturally now be paralleled by the increase in demand for the new method of transportation. This has been demonstrated to the sorrow of many American tourists who found their cars confiscated for war purposes with the small recompense of a scrap of paper signifying that they were to be repaid out of the future war indemnity to be collected by the Government of that particular country should it be victorious.

In a word, Europe is now using every kind of motor vehicle that it can lay its hands upon and is using them in a service far more arduous than that for which they were primarily designed. On one hand, we read of the entire British expeditionary force estimated at 150,000 men transported by motor trucks at rates of speed which outdo the efforts of troop trains. On the other hand, reports reach us of charges by groups of armored motor cars carrying batteries of artillery. The lesson learned in recent maneuvers are now being made use of in actual warfare. Whole batteries of artillery are being towed at speeds averaging in the neighborhood of 20 miles per hour.

American trucks had been looked upon with favor for war purposes in European countries. This is due to the fact that they are of wide tread with good clearance and large wheels, making them adaptable to the worst mountain roads. It is not surprising to learn that one of the Detroit companies has already received a cablegram from one of the European nations now at war, asking how soon the factory could ship 100 motor trucks to its seaports. This is but a forerunner of a practically certain demand, as armies now operate at considerable distances from their bases and a vast supply of vehicles is a necessity.

Export Market Large

It is not alone in Europe that a shortage of cars will make itself felt, but as has been already completely realized by this country, nations to which cars were formerly exported from the Continental and British factories will demand the American product if only through sheer necessity. The passage of the shipping bill will put at the disposal of American manufacturers a greater tonnage than has borne the American flag for many years.

Still another phase which has been mentioned by the sales manager of one of the big production companies is that the cars which are temporarily held here, and that would otherwise be exported, would be of value in meeting the abnormal demands that are always made by dealers in the opening of a new season. Thus, the full attention of the factory can be concentrated on the supplying of the dealers' demands at its heaviest period and then, this demand satisfied, attention can be given to the newly-developed export field.

It is not only in the United States that America's chance to establish her commercial supremacy has been recognized. One of the foremost financial experts of Great Britain prophesies that the war will bring great wealth to American industries and an economic benefit to the people of the United States. He predicts that Americans will be able to sell their goods at prices which will give them a larger income than could possibly be realized had there been no war.

America—the Important Producer

America cannot be criticized ethically for taking advantage of the opportunity presented by the calamity which has befallen a large part of the civilized world. The sympathy of the people of this country has gone out to distressed nations in a way that history has never before recorded. Still, the enormous demand created by the fact that men who formerly gathered the crops of Europe are now shouldering guns in the defense of their countries must be met largely by this country. The United States, as one of the principal grain producing countries in the world, will exchange its products for the gold that Europe has hoarded for its war. The American farmer and the American manufacturer, the producers of the country, will gain, and they in turn, with the enormous purchasing power put into their hands, will carry with them every industry.

History has been made by the motor car in this war. Nothing has had as much to do with the speed of mobilization as the power driven vehicle. Independent of rails and capable of traversing parallel roads simultaneously, immense trains of motor trucks and even passenger cars, were one of the chief factors in making possible the rapid assembly of the huge armies of armed men. Cavalry and motor-towed artillery were the factors that made up the personnel of the almost unbelievably rapid German advance across the difficult country to Brussels. The entire tactics of war have been affected by the possibility of bringing heavy guns to the front almost as rapidly as light scouting parties of cavalry.

Officers have made important use of speedy passenger cars in keeping in touch with headquarters and the motorcycle brigades are recognized as one of the most important branches of scouting service. From the main base to the sub-bases the commissary departments of the various armies are making full use of vehicles that were formerly in commercial service. And even from the sub-bases to the points of distribution along the fighting front, trucks are used wherever the roads render them possible.

Member of the Audit Bureau of Circulations

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

War Truck Requirements

INTERCHANGEABILITY is one of the great factors in motor trucks for war purposes on the march, with motor trucks for commissary, for ammunition, for guns and for transporting infantry requires that the trucks used be as standardized and interchangeable as possible. If a front wheel of one is crushed it should be interchangeable with that of another.

Supply parts have to be carried for these trucks, and if two different pieces are carried for two trucks in place of one, the handicap on the army corps is correspondingly more. The French government has required that trucks for subsidy be standard in certain respects, but there is yet much to be done.

Some years ago more or less wonder was expressed at the army requirements that a motor be capable of using three different fuels, gasoline, benzol and alcohol with the same carbureter. The present war, with its shortage of fuel, has demonstrated how essential it is to be able to use one or the other. There are places in the zone of activities where only benzol can be had; at another place alcohol only is available; and at a third gasoline is on hand. It was a wise precaution that made it imperative that a motor be capable of using one or all of these fuels.

The performances of trucks with four-wheel drive is being watched and the reports from the front on the relative performance of trucks using all four wheels as drivers and those driving by the rear wheels only or front wheels only will have an important bearing on the purchases of our war department.

Used Car Standards

SO GREAT is the evil of over-valuing used cars by dealers taking them in trade on new machines that the dealers' association in Chicago is to be congratulated on its initiative in publishing the first volume of Central Market Reports on Used Cars, for the use of its own members as well as for distribution throughout the country.

Dealers from coast to coast have erred in allowing too liberally on old cars in trade deals. In some cases it was because of too great a desire to make a sale, and in other cases it was through ignorance. The Central Market Report should be a great aid. It is a guide to valuation by the dealer on cars other than those he sells. We have our weekly markets on iron and steel; we have our daily stock quotations; we have our markets on scores of commodities, and the institution of a market standard on used cars is but in line with an old-established custom.

How many buyers of iron or steel would think of making a purchase without consulting the market report? How often will a dealer in live stock make sales or purchases without looking over the markets? Then, why should not our motor car dealers be provided with a similar price list? There are many reasons why every dealer should have such a standard of used-car values close at hand. It is impossible for the dealer to carry in mind the actual market value of all makes of cars that he may be called upon to handle in a trade deal. The Central Market Report at once becomes his book of reference in these matters; in fact, it goes further, and becomes his guide.

The fact that the prices quoted in the Central Market Report are based on actual sales lends value to it, and puts it on a par with any other authentic reports. The values published for a certain make of used car are not fictitious but are actual. They give hard facts. They will have the effect of making the dealer conservative.

We should have the Central Market Reports for motor trucks as well as for passenger cars. The evil of over-valuation is present in the truck field as well as in the passenger car trade. Central Market Reports on trucks are needed even more than in passenger cars, because of the greater ignorance among dealers as to the actual selling values of used trucks. Many dealers are new in the truck industry. They have little actual knowledge of used trucks, and are consequently the more in need of some standards of value as furnished in the Central Market Reports. It is to be hoped that soon the price of used trucks will be incorporated in these reports and that the evil of over-valuation will be wiped out before it has done the injury to the truck dealer that it has done to the passenger car dealer.

N. A. C. of C. Holds Optimistic Session

Find That War Slowed Up Industry First 2 Weeks in August But Last 2 Weeks Show Increase of 2,401 Carloads Over 1913 in Car Shipments—Truck Convention Postponed

NEW YORK CITY, Sept. 2—Conservative optimism on the fall trade in automobiles prevailed at the directors' meeting of the National Automobile Chamber of Commerce, representing ninety-three automobile manufacturers at the New York headquarters yesterday. The European war resulted in an almost complete shut down of the automobile trade during the first 2 weeks in August, but reports received yesterday show that a reaction has taken place and shipments for the last 2 weeks were far ahead of the same period last year. It is believed that the trade this fall will be almost up to expectations.

Increase in Shipments Over 1913

The Traffic Department figures showed that during August, 1913, the automobile industry shipped 4,469 carloads, while last month the shipments were 6,870 carloads, most of which were made during the last 2 weeks of the month.

It was decided that the present was an inopportune time for a convention of commercial vehicle manufacturers and a date for holding one will probably be decided upon for late in the year.

There was a most interesting report from the Patents Committee relative to the automobile patent situation and also in regard to the proposed changes in the patent laws at Washington.

Resolution on Accessory Makers' Suits

The directors adopted a resolution expressing their disapproval of various accessory manufacturers having controversies among themselves on patent rights, bringing suits against the makers of motor cars. The resolution is as follows:

WHEREAS members of the National Automobile Chamber of Commerce have been annoyed and embarrassed by threats of patent infringement and by patent infringement suits brought against them or against their customers and users of their cars by certain manufacturers of automobile accessories and parts; and

WHEREAS it is unnecessary for such manufacturers of accessories and parts to bring suits against automobile manufacturers, vendors and users of motor cars in order to assert their rights under their patents, inasmuch as such manufacturers of accessories and parts have ample recourse against the infringing manufacturers of such accessories and parts;

THEREFORE, BE IT RESOLVED that the directors of the National Automobile Chamber of Commerce regard any such suits by accessory and parts manufacturers against motor car manufacturers, vendors or users of motor cars as being unwarranted, unfriendly and against the best interests of the industry; and be it further resolved that the Motor and Accessory Manufacturers Assn. be advised of the attitude of this Chamber on this subject with the end in view of giving all manufacturers of accessories and parts due notice of the attitude and feeling of the National Automobile Chamber of Commerce.

To Make Pope Car Parts in Hartford

HARTFORD, CONN., Sept. 2—*Special Telegram*—Announcement is made today of continuation of the manufacture of parts for Pope-Hartford passenger cars, trucks and fire apparatus to be conducted here. The purchase of this business in its entirety by the Pope-Hartford Co., of Connecticut, the new corporation, includes all the parts finished and in process, tools, jigs, fixtures, patterns, drawings, tracings, formulas, and everything pertaining to this important branch of the business. The repair and service department formerly operated by the Pope company will also be continued by the new company at the main works on Capitol avenue. This department will be manned by experts selected from the best men in the employ of the Pope Mfg. Co.

The Pope-Hartford Co. of Connecticut is composed of men who have been connected with the design, manufacture and sale of these cars since the production of the first model in 1902. The officers of the new company are: Wilbur C. Walker, president; Ralph A. Barkman, vice-president; Charles E. Walker, treasurer, and Joseph A. Taylor, secretary. The capital stock authorized is $200,000, divided into 200 shares, par value, $100. There is $60,000 of preferred stock and $140,000 of common stock. The amount of capital stock with which the corporation intends to begin business is $10,000. The incorporators are: W. C. Walker, Charles E. Walker, of Hartford and Ralph A. Barkman, of West Hartford.

To Handle Dodge Cars

The Hartford Motor Car Co. of Hartford, has filed a certificate of incorporation. It proposes buying, selling, and dealing in motor vehicles. The company is the Dodge representative in this section. The capital stock authorized is $50,000 divided into 500 shares, par value $100. The amount of capital stock with which the corporation intends to begin business is $10,000. The incorporators are: Frank M. Ridder, W. C. Walker, Charles E. Walker, of Hartford and Ralph A. Barkman, of West Hartford.

To Test Washington Anti-Glare Regulation

WASHINGTON, D. C., Aug. 22—New traffic regulations affecting motor car drivers went into effect here this week and met with general approval with the exception of the provision prohibiting the use of brilliant headlights with reflectors. The authorities hold that cars equipped with headlights with reflectors cannot be used at night unless the glass is covered with paint, cheesecloth or some similar material. The use of dimming apparatus is also declared to be illegal.

A test case was made this week when R. H. Martin, manager of the Buick Motor Co., was arrested for driving a car equipped with electric headlights on which there was a dimmer attachment. He was fined $10 and promptly noted an appeal to the court of appeals. It is expected it will be several months before the case will be reached by the higher court. In the meantime the district commissioners are being flooded with protests against the headlight regulation, the protestants pointing out that lights with dimmer attachment should be allowed. There is a possibility that the commissioners will so amend this regulation as to make the use of such lights legal.

Combination Rubber Takes Over Keaton Tire

NEW YORK CITY, Aug. 31—The Keaton Tire & Rubber Co. has been taken over by the Combination Rubber Mfg. Co., this city, which will continue the manufacture of special brand tires and tubes, and take over the business in its entirety.

H. A. Forbes, formerly general manager of the Keaton company is now connected with the Combination company as manager of its tire department, and F. C. Braden is now identified with the company as sales manager of the tire department.

Benham Mfg. Co. Asks for Dissolution

DETROIT, MICH., Sept. 2—*Special Telegram*—A voluntary petition for dissolution has been made by the Benham Mfg. Co., which has been making the Benham six, which was formerly known as the S and M. The petition was made upon the suggestion of the creditors' committee and the Union Trust Co. has been appointed receiver and will decide after verification of the concern's condition and the inventory, what the best policy will be concerning the future of the company. According to the latter's statement, the liabilities amount to $76,889 and the assets to $109,000.

Canada Buys Trucks—17 Go to War Camp

OTTAWA, ONT., Aug. 28—The Militia Department of the Canadian Government has supplied itself with motor trucks with the least possible delay. The government has purchased twenty-five, the idea being to have these trucks, all of 2-ton capacity, accompany the Canadian contingent abroad, there to be utilized for the hauling of supplies and other work which heretofore has been done with horses.

The details of the purchase were handed over to T. A. Russell of the Russell Motor Car Co. of Toronto by the Militia Department. The following well known manufacturers received the orders:

The Russell Motor Car Co., of Toronto, 8; the White Company, 5; The Packard Company, 4; The Gramm, Walkerville, 4; and the Reo, 4—twenty-five in all.

A stipulation of the orders was quick delivery, and how soon this was accomplished is illustrated in at least one instance. The White Company received its orders on Sunday, the 15th, and at 2:30 o'clock on the following Tuesday, the 17th, these five motor trucks were in Canada and on their way to Val Cartier where its troops are mobilizing.

Cars, Trucks and Accessories Contraband

NEW YORK CITY, Sept. 1—At a meeting of the New York Chamber of Commerce held last week a statement of information to shippers was adopted. This is of interest in view of the fact that motor vehicles, gasoline and lubricating oil have been declared contraband of war. The report states, that goods shipped to a neutral destination are exempt from capture whether carried in an American, neutral or belligerent bottom. The only exception to this rule is when goods, though shipped to a neutral port, are intended for a re-shipment to some point in the territory of the nations at war. The burden of the proof is then on the captor who must show beyond reasonable doubt that such re-shipment was intended.

The report further takes up the question of ordinary marine and war insurance, the difference between the two classes of contraband and upon what points the capture may be justified. A copy of this statement may be procured by addressing the committee on problems of foreign shipments, during the war, in care of the New York Chamber of Commerce.

Bosch Unaffected by War in Europe

LONDON, ENG., Aug. 31.—*Special Cable*—Editor THE AUTOMOBILE—The Bosch Magneto Co. informs me that it has supplies of magnetos available for all possible requirements. The plant is available if necessary for production. The general state of trade in this country is as reported in THE AUTOMOBILE for August 30.—J. S. Critchley, president of the Institution of Automobile Engineers.

Krit Has New Model for $850

DETROIT, MICH., Sept. 1—*Special Telegram*—To meet the demand for a lower priced car, the Krit Motor Car Co., Detroit, will bring out another model to sell at $850 with electric cranking and lighting.

This new Krit, designated as model O, has the same motor and chassis as the models selling at $995, but it is less of a de luxe proposition, though it is just as good from the standpoint of service. The motor has a bore of 3¼ inches and a stroke of 4 inches, and is an L-head type with block cylinders.

Though the body is a streamline type, it is not so refined; it has the familiar paneled edges which are absent on the other car and is a strictly manufacturer proposition.

To illustrate the equipment differences making possible this lowering in price as compared with the other Krit, the top is not of the one-man type, though it is of a good grade of mohair; there is no gasoline tank gauge; the fenders are not crowned, though preserving the popular curve. The Bosch magneto is not fitted, the new Disco combination electrical system taking care of ignition as well as lighting and cranking. A Schebler carbureter will probably be used.

Though not so refined as its running mate, it is pointed out that this Model O Krit is very good value, for it possesses many high-priced car features. For instance, there is the coped over radiator, tapered bonnet, left drive, rain-vision and ventilating windshield, leather-covered instrument board, Stewart speedometer, demountable rims, and tire carrier at the rear with the gas tank in the cowl.

It is probable that a large proportion of the Krit factory will be devoted to the making of this model, a schedule of about 6,000 of them being figured on. Due to the low price, this car is to be had only in stock form. No changes will be made in color, equipment or fittings. Both roadster and touring car are offered at $850. Deliveries are underway, the first carload going forward to-day.

Stutz Brings Out New Light Four

INDIANAPOLIS, IND., Aug. 31—A light four runabout selling at $1,450 has been announced for 1915 by the Stutz Motor Car Co. In addition another 1915 model is the Bull Dog which consists of a close-coupled four-passenger tonneau on the standard four-cylinder Bearcat roadster. This car sells for $2,250.

The new light four is standard in every way. It has a four-cylinder L-head block motor, 3.75 by 5 inches, made by the Wisconsin company. A cone clutch and the Stutz gearset and rear axle, combined in one unit, are continued. The wheelbase is 108 inches and 32 by 4-inch tires mounted on wooden wheels are used. The front axle is of Timken make and the springs are semi-elliptic all around. The Remy starting and lighting system has been adopted and carburetion is furnished by a Stromberg carbureter.

Right steering and right control are used, the steering gear being a Gommer. The equipment includes Hartford shock absorbers, Warner speedometer, Baker demountable rims, trunk and tire carrier and the body is ironed for a top.

The Bull Dog model is identical with the present Bearcat with the exception that Bosch ignition is used and the gravity tank has been displaced by a pressure system.

Apperson Light Four and Six Appear

KOKOMO, IND., Sept. 1—Apperson Bros. Automobile Co. has added to its line a light four and a light six streamline model. Both cars will be produced in quantities to sell at popular prices.

The building of these two models is an innovation for this company, for they have devoted years to the production of high-powered cars.

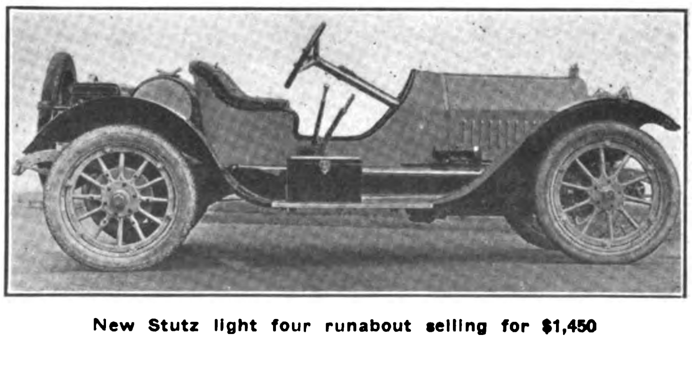
Like all Apperson cars, these two new models were designed by Elmer and Edgar Apperson. The price of the light six is $1,785, with full equipment; and the four is $1,485, fully equipped. The company builds in addition to these cars, other fours and sixes, ranging in price from $1,685 to $2,350.

Trucks Abused by Use of Trailers—C. of C.

NEW YORK CITY, Aug. 28—Inquiries addressed to members of the National Automobile Chamber of Commerce regarding the desirability and economy of using trailers with standard motor trucks have been answered in detail by the following twelve companies:

Avery	Kissel	Speedwell
Baker	Locomobile	Velie
Federal	Packard	Waverley
General Motors	Pierce-Arrow	White

The preponderance of opinion is decidedly against the practice except under very favorable conditions, such as level, smooth, hard roads, slow speed and proper handling. Given such conditions the standard truck may be used successfully for hauling trailers, but under no circumstances should a trailer be used without the consent of the manufacturer, as the guarantee does not contemplate such use. Under any other conditions the practice is of very doubtful economy; therefore truck manufacturers do not encourage the use of



New Stutz light four runabout selling for $1,450 trailers unless they examine the field of operation and know that their trucks can handle the work with trailers under the conditions.

—

Low Gear, Non-Stop Test by Franklin Dealers

SYRACUSE, N. Y., Aug. 29—On Thursday, September 24, the Franklin Automobile Co., through its agents, will hold a nation-wide, 100-mile low-gear, non-stop cooling demonstration. The object of this test is to demonstrate the fact that the air cooling system used on the Franklin cars is adequate to take care of the needs of the motor under the most trying circumstances.

The test will be run in about the same manner as the fuel economy test which was made by the Franklin dealers on May 1, 1914, when ninety-four stock Franklin six-30 touring cars averaged 32.8 miles on 1 gallon of gasoline. Every Franklin dealer has been invited to enter the test with a Franklin six-30 car. The run is to be started at 8 a. m. on September 24, regardless of weather conditions and is to be supervised by two or more disinterested observers. The engine is to be kept running throughout the entire demonstration and the cooling system is to be left in its ordinary condition. It is expressly forbidden in the rules that extra oil be supplied either to the motor itself directly, or through the gasoline.

The hood is not to be raised during the run and before starting all the oil is to be drained out, and the fresh oil replacing it is to be carefully measured. The amount remaining in the car is also to be measured after the run to obtain information on the amount used. The number of gallons of gasoline used during the run are also to be measured, and the finish must be within 10 hours of the start.

A complete booklet instructing the agents in the methods of making the test has been issued in order that every agent will carry off the run in a similar manner. In going 100 miles on low gear in 10 hours, each cylinder fires the same number of times as in going 336 miles on high gear. At the conclusion of the run, the time consumed, weather and road conditions, oil and gasoline consumption, will be telegraphed to the company at Syracuse and following this an affidavit will be made out detailing the results of the test.

—

Chandler Co. Developing Exports

CLEVELAND, O., Aug. 27.—"We have been shipping cars to countries outside of Europe ever since the war has been in progress," said sales manager C. A. Emise, of the Chandler Motor Car Co. "We are going after the trade in South America, South Africa and Australasia and believe that American manufacturers will in time get the biggest part of the automobile business done in those countries.

"American automobile manufacturers have been getting many automobile supplies and accessories from Europe: for instance, ball bearings, spark plugs, magnetos from Germany; silent chains from England; upholstering material from France; special alloys, steel, windshield glass, etc., from other European countries. The war now gives an unexpected opportunity to American manufacturers to supply some of these materials or supplies and it depends entirely upon them to have the demand become permanent for their goods.

"As far as our own company is concerned, I may say that we have a very large supply of all materials and supplies and accessories of European origin, and are in no way worried. We will make all the cars we have planned for 1915 and we are looking forward to a big business year."

—

Chalmers Reduces Light Six Price $200

DETROIT, MICH., Sept. 1—*Special Telegram*—The Chalmers Motor Car Co., Detroit, has reduced the price of its small six-cylinder model from $1,850 to $1,650. This cut of $200 means a sheer reduction of this amount, the car at its new price being identical in every respect as heretofore. This price reduction brings this small six into the price zone of small sixes the public has been observing closely for months past.

—

W. R. Chandler Gets Eastern Sparton Territory

NEW YORK CITY, Sept. 1—The Sparks-Withington Co., Jackson, Mich., is greatly increasing the scope of its retail activities. W. R. Chandler has been allotted a large territory in the East, including New York, Pennsylvania, Delaware and the District of Columbia, and has established headquarters in the U. S. Rubber building, Broadway and 58th street.

Big Rubber Stock for Goodyear—Tire Prices Hold

—

Some Companies Still Announcing Price Raises —Scarcity of Boats and Tight Exchange Cause Low Imports

NEW YORK CITY, Aug. 31—Tire prices have undergone no material changes this week. The Pennsylvania Tire Co. announced, however, it has increased the price on its vacuum tire 5 per cent. and an increase of 12½ per cent. on its plain tread stands.

Those tire prices which remain the same as before the war are as follows: Kelly-Springfield, Lee, McGraw, Michelin, Overman, Goodyear, Ten Broeck, and Swinehart. The following tire prices are increased: Empire, 12.5 per cent.; Federal, 12 1-2 per cent.; Firestone, 12 1-3 per cent.; Fisk, 15 per cent.; Goodrich and Diamond, 12 1-2 per cent.; Pennsylvania, 12 1-2 per cent.; Republic, 12 1-2 per cent.; United States, 12 1-2 per cent., and the Lee, 12 1-2 per cent.

The Goodyear Tire & Rubber Co. has obtained 1,500,000 pounds of rubber from the London market. This big supply is now nearly all on the way to the factory in Akron. The company has since taken other steps to insure a continuous supply.

The other companies have succeeded in getting a small lot of rubber, but the lack of ocean transportation facilities has greatly hindered them in getting even this small lot.

The demoralization of the foreign exchange market is giving fully as much trouble. As is well known, the principal sources from which crude rubber are obtained are Brazil and the Far East. In both cases the product is paid for through London. Unless the foreign exchange market improves substantially in the near future the buying of crude rubber will be on a reduced scale.

It is expected that 11 of the guayule rubber factories in Mexico will have resumed operations by September 5. Preparations are being made by the Intercontinental Rubber Co., which is composed of Aldrich-Rockefeller interests, to run all of its factories, including the large plant in Torreon, full time. Gangs of men have also been set to work cutting the guayule shrub upon the 2,000,000-acre Cedros hacienda in the State of Zacatecas, that is owned by the company, and a large supply of the raw product will be on hand at the different factories in a short time. It is stated that the recent advance in the price of rubber is stimulating activity in the guayule industry, and that there will be several other large factories established in the Torreon district and in the upper border region of Texas if prices continue high.

Notwithstanding the predictions made in the beginning of this year that, owing to the decrease in prices, crude rubber shipments from the Amazon Valley would show a falling off, variously estimated from 15 per cent. to 25 per cent., it would appear that the amount exported in the crop year of 1914-15 was only slightly less than the average for the last 5 years and but 9.4 per cent. below the record season of 1913-14.

For the crop year ended July 31, 1914, the exports of crude rubber from the Amazon Valley, by port of shipment, were:

There is no doubt that if prices continue to rule low it will affect shipments, but for the present at least the output will continue about as given above.

—

DETROIT, MICH., Aug. 27—The directors of the Packard Motor Car Co., this city, have declared the regular quarterly dividend of 1¾ per cent. upon the preferred stock, payable on September 15 to the stockholders of record upon the close of business on September 5.

Big Trade Boom in Newark—Business Grows 73 Per Cent.

Cars Selling Under $2,500 Seem the Most Popular in 1914 Sales—Dealers' Reports

NEWARK, N. J., Aug. 29—Never before in their history have the automobile dealers in this city reported such remarkable sales. For the first 7 months of 1914, the average increase in sales is 73 per cent. The cars selling under $2,500 seem to be the most popular.

The Ford company again leads in sales, which number 900, an increase of almost 200 per cent. Philip Plaistridge, the new Ford dealer, expects sales to reach the 1,200 mark this year.

The following is a report in detail:

Velie and Briscoe—Sold seventy-one cars. No increase over 1913. Shipments have been prompt and their delivery immediate. Big 1915 advance in sales. During July and August twenty-eight cars have been sold. The five-passenger touring car is most popular.

Reo—Best year it ever had, with a 300 per cent. increase. Sold 499 cars, including wholesale and retail. Wholesale amounted to 317, its Paterson branch alone selling forty-two. Sold ten cars in last 9 days. Maintains its own service station with a monthly inspection of its customers' cars. Its August business was $9,000 more than the same month in 1913.

White—Reports good business, with a 15 per cent. increase.

Buick—Reports 52 per cent. increase over 1913 sales. The 1915 sales are 50 per cent. better than for the same period in 1913. Predicts the biggest fall business in its history. It is 6 weeks ahead of its factory allotment.

Oakland—Business on a par with 1913. 1915 sales are very promising.

Chalmers—Sales for 1914 were 35 per cent. better than 1913. Expects good 1915 sales. Its allotment is 30 per cent. larger this year.

Mercer and Chandler—Sold 44 cars in 1914 as against 29 for 1913, a 54 per cent. increase.

Pierce-Arrow—This concern did a remarkable business for 1914. Including its service-station work, its special painting department, its second-hand car department and its new car sales, the business amounted to approximately $1,000,000. The second-hand car business amounted to $185,000. Sales for the new series model are 50 per cent. ahead of last year for the same period. Truck business is about 60 per cent. ahead of the preceding year. Thirty per cent. of its passenger cars sales are in closed cars.

Stutz and King—This agency shows a 75 per cent. increase, its sales amounting to sixty-five cars.

National—Sold forty-seven cars in 1914 and thirty-five in 1913, a 34 per cent. increase. Its allotment will be about 40 cars this year. Touring cars are most popular.

Oldsmobile—Has increase of 25 per cent. Will have allotment of 250 of the small-car type and 40 big cars.

Overland—The rush for 1915 cars has brought the agency 3 days behind in its orders. Starting February 1, the sales during the first 5 months of this year have equaled the 12 preceding months. The sales for 1914 are approximately 100.

Locomobile—Sales were on a par with 1913.

Market Reports for the Week

The usual changes occurred in this week's market reports. Rubber rose to $0.77 at a gain of $0.22 over Thursday's quotations. Owing to the smallness of supplies on hand, nominal conditions prevail. It was reported that the London market was firmer for plantations, but no details as to prices were available. Petroleum prices are steady. Quotations on cyanide potash have stopped. An importation, however, was noted of 150 cases of cyanide. Sulphuric acid is steady at $0.90. Both Bessemer and Open-Hearth steels rose to $20.50 at a gain of $0.50 per ton. One interesting development in the steel market was the practical placing of an export order for 2,000 motor trucks and ambulances with an American manufacturer, who is in turn placing contracts for steel shapes to be used in the construction of the various parts. The contract price of the trucks is about $4,000 each, making the total $8,000,000 for the full contract. Copper exports in August amounted to 44,000,000 pounds, while the imports at Atlantic ports is estimated at 22,400,000 pounds.

Recent Trade Changes in Newark

NEWARK, N. J., Sept. 1—During the last few weeks, a number of the automobile agencies have made important changes in the way of the addition of new cars or the establishment of new agencies.

L. J. Wyckoff, for many years the Ford agent for this city, has taken on two new cars, the Oldsmobile Four and the Saxon. The taking on of the small Oldsmobile follows somewhat the plan of the New York City Oldsmobile dealer, who has established a number of agencies throughout the city for the small car. The Oldsmobile Co. of New Jersey, 254 Central avenue, will in the near future become the state agency for the Oldsmobile cars. It expects to establish about fifteen small car agencies throughout the state.

Hereafter all sales of Stevens-Duryea cars for this territory will be conducted at the New York City agency, 1875 Broadway. The Newark service station, however, will be maintained.

A $5,000,000 Overland Stock Increase

TOLEDO, O., Aug. 29—The Willys-Overland Co. was authorized on Thursday to increase its capital from $25,000,000 to $30,000,000. Overland officials stated that the increase will be used in declaring stock dividends. The common stock was increased from $20,000,000 to $25,000,000 which, with the $5,000,000 preferred stock outstanding, makes the total $30,000,000. During the present month the company has brought in $250,000 worth of preferred stock for retirement, in accordance with the terms of its charter which specifies that amount to be applied annually in the retirement of preferred stock.

Anderson Electric Conventions in Series

DETROIT, MICH., Aug. 28—Instead of holding one single convention for all their branch managers, dealers, salesmen, etc., the Anderson Electric Car Co., which makes the Detroit electric vehicles, has been holding and will still hold several conventions.

One of the first conventions held was that of factory salesmen. Then there was a convention of branch managers, one of Pacific coast dealers, another of Southern dealers, one of Central West dealers.

At these meetings, which were held at the big plant on Clay and Riopelle, about 160 co-workers of the Anderson company from all over the country have taken part. The 1915 models were thoroughly explained; sales methods and plans for selling campaigns were talked about; there were exchanges of views concerning the second-hand electric vehicle problem and concerning the garage systems and facilities.

"We are now employing 1,200 men," said A. C. Downing of the Anderson company, "and the outlook for 1915 is very satisfactory to us. We are planning to build 30 to 35 per cent. more vehicles than we did this year, the demand all over the country being larger than ever.

"There seems to be a general tendency to help the electric vehicle business as we notice that many other trades or industries or business which heretofore could have assisted the electric vehicle trade in becoming bigger and expanding more rapidly are now coming to the front and helping. Probably the biggest improvement in this connection is the assistance given by the electric light companies, which are not only giving more favorable rates but are employing electric vehicle experts to give advice to electric vehicle users."

Briscoe Branch in New York—Other Agencies

New York City, Sept. 1—Changes in automobile agencies in the city, either planned or accomplished, are many just now. One of the most important is the opening of the Briscoe Auto Co., of which Rudolph L. De Lisser is the head. This company, a direct representative of the Briscoe factory, will have a store on Broadway just above the northeast corner of 58th street, at 1794 Broadway.

James W. Gilson, advertising manager of the L. P. C. Co., has been here arranging for an agency for the Lewis Six. Another car that will probably be represented by an agent instead of a branch hereafter is the KisselKar. Negotiations are pending with one dealer to take the local retail end. C. H. McCausland will retain charge of the wholesale business of the Atlantic seaboard.

C. B. Derby & Co., local agent for the Abbott-Detroit and Westcott automobiles, has been appointed distributor in Brooklyn for the Oldsmobile. They have established offices and salesrooms at 1270 Bedford ovenue.

The Colt-Stratton Co., eastern distributor of the Cole car, has secured the distribution of the Dodge Bros. car for this territory.

The Greenhut Department Store has taken over the distribution of the Argo car for the Metropolitan district and all surrounding territory, including Long Island, Brooklyn, Staten Island, Westchester County and Fairfield, Conn. This department will be in charge of T. P. Ward. A service department will be installed, near the store, probably next door.

Northwest Dodge Allotment Snapped Up

Detroit, Mich., Aug. 27—A. C. Templeton, district manager for Dodge Brothers in Minneapolis, Minn., after a 6 weeks' tour through Minnesota, the Dakotas, Nebraska and Wyoming, has returned to Detroit, having closed contracts for 75 per cent. of all the cars which Dodge Brothers have provided for that section of the country. In some parts of the state visited by Mr. Templeton the crops have been much heavier than in any previous year and are also bigger than in other sections of the state, this being due to the fact that blight and the terrific heat has caused some damage to the crops in certain sections.

Splitdorf Charges Patent Infringement

New York City, Aug. 31—The Splitdorf Electrical Co. has brought suit against the Eisemann Magneto Co. charging infringement of patent No. 1,102,385 covering improvements in magneto mounting. The Splitdorf company is the assignee of Ernest W. Brackett, Newark, N. J., and claims that the Eisemann company made or sold or caused to be made or sold in the borough of Manhattan, magneto mountings embodying the invention of the patent. The plaintiff prays for a writ of injunction, as well provisional as permanent, and also for damages and costs of the suit.

The Eisemann Magneto Co. claims that the so-called invention described in the patent was manufactured and marketed by others for some years before the granting of the patent in suit. The Eisemann company will contest the suit on this ground.

Studebaker Demand Biggest in Years

Detroit, Mich., Aug. 27—According to first vice-president A. R. Erskine of the Studebaker Corp., the demand for Studebaker cars is the heaviest the corporation had in many years and at the present time the concern is more than 3,000 cars behind its schedule of deliveries.

"We are shipping 160 to 180 cars daily and doing our utmost to catch up with this unprecedented situation in our plants," said Mr. Erskine. "Anyone who thinks that the war in Europe will affect to any great extent the automobile business is mistaken. It seems to me from the reports I have received from all over the country that the farmers of the United States will buy more cars than in any previous year, while in most cities and towns the reports from agents, representatives and branches, are the most encouraging and indicate a bigger demand than ever before."

Reorganizes Standard Roller Bearing Co.

Philadelphia, Pa., Sept. 1—In conjunction with manufacturing and banking interests in Philadelphia, New York and other Eastern cities in the East, S. S. Eveland, former president of the Standard Roller Bearing Co., which went into the hands of receivers last year, has plans under way for a reorganization of the company.

At the headquarters of the Eveland Engineering & Manufacturing Co., Mr. Eveland could not be seen today, as it was said that he was attending an important conference bearing on the reorganization plan. It was announced, however, that such a plan was nearing completion, but until the preliminaries were cleared up it was not possible to get more than a mere outline of what was to be accomplished.

The only information forthcoming was to the effect that a substantial payment to the creditors' committee had been made to bind the bargain.

It is understood that the plan of reorganization contemplate the payment to the company of a large sum for working capital, and also the payment to creditors of a certain percentage of their claims, including debenture holders, banks and mercantile creditors, the balance to be paid gradually. All stockholders will retain an interest in the concern.

Receiver for American Voiturette Co.

Detroit, Mich., Sept. 1—*Special Telegram*—The Detroit Trust Co. has been appointed receiver for the American Voiturette Co. of this city, builder of the Car-Nation small car and the Keeton car. H. L. Stanton, who is in charge of the receivership, states that all creditors are being notified by circular letter of the situation and that work will be immediately begun on making inventory and issuing a statement of the assets and liabilities of the concern. The order of the appointment of the receivership was signed by Judge Sessions of Grand Rapids and the receivership is in the United States District court, eastern district of Michigan in equity. The application for the receivership was made by a creditor of the organization.

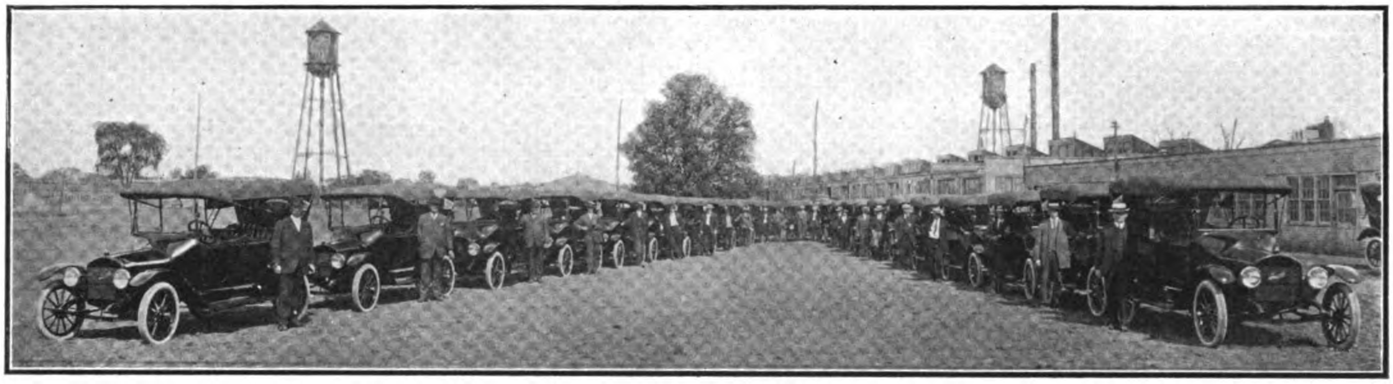
The receiver states that the liabilities according to the company's statement approximate $231,000. No statement of assets is made, but there is material for 600 Car-Nations on hand in construction and material for 100 Keetons. The receiver will carry on manufacture of these parts as soon as the inventory is taken. Since April 1 the company has manufactured 1,200 Car-Nations and has distributed these through more than a dozen centers. A representative of the concern makes the statement that the narrow tread, which has demonstrated its value on all kinds of roads has been generally criticized by all dealers selling standard tread cars.

Hoosier S. A. E. Prepares Winter Program

Indianapolis, Ind., Aug. 29—At a dinner and meeting of the Indiana branch of the Society of Automobile Engineers, at Crows Nest, near Indianapolis, a few days ago, plans for the winter meetings were discussed. One meeting will be held each month and an interesting program of technical papers and other features will be arranged for each meeting. A committee is now at work on a program for the first meeting, which will be held the evening of September 9 at the Claypool Hotel, Indianapolis. Efforts are to be made to increase the membership during the meeting.

Boston, Mass., Aug. 31—On motion of the creditors, Judge Dodge in the U. S. District Court today postponed the question of sale of the Walpole Tire & Rubber Co., until October 15.

Third annual outing of the Motor Truck Club, New York City



Twenty-five dealers from western New York State at the Maxwell plant taking delivery on new Maxwells

De Palma Will Drive at Brighton Beach Races

NEW YORK CITY, Aug. 27—The 2-day automobile race meet scheduled for Saturday, September 5 and Labor Day, September 7, at Brighton Beach track, will bring forth a few of the Elgin stars. Ralph De Palma will drive the same Mercedes with which he won the recent two Elgin road races, also the Mercedes with which he captured the last two Vanderbilt cup races and the Elgin road race in 1912. His brother, John De Palma, will drive one of these Mercedes cars in some events and possibly a Peugeot racer in others. Ralph Mulford is at present on his way from Elgin, driving his Peugeot over the roads.

Harry Grant will probably drive a Sunbeam. Jack Le Cain of Boston will drive one of the two Chevrolet specials entered; the other driver is not nominated as yet. Dickinson has entered a Stutz; Strang will drive a 120-horsepower Benz; Vail will be at the wheel of the old Ford 999. Armour Ferguson will probably drive his 160-horsepower Peugeot, while other entries are George Smithson in a Cole, Neil Whalen in the Greasy Bullet, and a Lozier, Fiat, Paige-Detroit, Isotta, National and a Mercer.

Race Meet at Boston, October 10

BOSTON, MASS., Aug. 31—In connection with the First Annual Light Car and Cyclecar Show to be held at Horticultural Hall, Boston, October 12 to 17, there will be a race meet on Combination Park's 1-mile dirt oval at Medford, Mass., on Saturday afternoon, October 10. The card of events as arranged by manager E. P. Blake calls for a 2-mile Class A race for cars up to 71 cubic inches cylinder displacement, a 5-mile race for Class B cars from 71 to 100 cubic inches cylinder displacement, a 5-mile Class C race for cars from 101 to 125 cubic inches and a 25-mile free for all race for all cars up to 125 cubic inches and 1,150 pounds chassis weight.

Postpone Wisconsin 3-Day Tour to Sept. 7

MILWAUKEE, WIS., Aug. 31—The fourth annual tour of the Wisconsin State A. A., scheduled for September 2, 3 and 4, has been postponed to September 7, 8 and 9 so that the run may start on Labor Day and contestants will actually spend only 2 working days on the road. When entries closed August 27, there were eight actual entries and five conditional entries, depending upon the arrival of 1915 models. To accommodate the uncertain entrants, the tour was set forward 5 days, and in the meantime additional entries will be solicited.

The cars already officially nominated are: Mitchell, Mitchell Automobile Co., Milwaukee; Franklin, Sanger Automobile Co., Milwaukee; Chevrolet, Olson-Pauly Co., Manitowoc, Wis.; Buick, Buick Motor Co., Milwaukee; Studebaker, Wolleager Automobile Co., Milwaukee; new R. C. H., Creek Motor Sales Co., Milwaukee; White, White Automobile Co., Milwaukee; Oakland, Creek Motor Sales Co.; Reo V, Curtis Automobile Co., Milwaukee; Jeffery 4, Reeke-Osmond Motor Car Co., Milwaukee. These ten cars will be supplemented by at least five others, making an entry list of 15 for the only reliability-economy tour to be run in the United States this year.

The tour will be run under grade 1 rules of the A. A. A., with supplementary rules framed by the W. S. A. A. to cover the economy feature of the run. It will be run in eight divisions, for economy purposes, the classification being according to price, as follows: Up to $450; from $450 to $800; from $800 to $1,200; from $1,200 to $1,600; from $1,600 to $2,000; from $2,000 to $3,000; from $3,000 to $4,000, and over $4,000.

There will be eight trophies, donated by *Wisconsin Motorist*, one for each class in the economy test; the *Milwaukee Sentinel*, $1,000 gold cup as a sweepstakes prize; the *Milwaukee Free Press*, cup for reliability, and the Emil Schandein cup for private owners. The Schandein cup class has already two entries, and officials of the W. S. A. A. say they will be satisfied to have a total list of 5 private owners. The tour will last 3 days and cover approximately 475 miles through the most thickly populated section of Wisconsin.

Races and Show at Michigan State Fair

DETROIT, MICH., Aug. 31—The chairman of the contest board of the American Automobile Assn. has informed the promoters of the 2-day race meet to be held on the Michigan state fair track September 6 and 7, that the ban upon the track has been lifted for those 2 days. Among the prominent race drivers thus far entered to drive in the races are: Bob Burman, Louis Disbrow, Johnny Rainey, Fred Horey, Charles Coey and Harry Davison.

Half Fees for Owners Alone in Ohio

COLUMBUS, Aug. 29.—The attorney general of Ohio has handed down an opinion in which he holds that the provision of law for half fees after September 1 refers only to automobile owners and not to chauffeurs, dealers or manufacturers. After that date the fees for registering gasoline cars will be $2.50; electrics $1.50.

State Registrar Shearer believes there will be 120,000 cars registered in the Buckeye State as the number is now 115,000.

Amateurs Win from Trade in Chicago Run

CHICAGO, ILL., Aug. 31—The fourth annual team match between amateur and trade members of the Chicago Motor Club for the A. J. Banta trophy took place Friday and Saturday of last week and resulted in a victory for the amateur team by a score of 181 for the victors and 251 for the losers. The trip was to St. Joe, Mich., and return, a journey of about 210 miles. The amateur team was made up of six cars, while the trade team had the same number. On the winning side L. H. Phiffer in a Velie, O. W. Hahn in an Overland and E. Turner in a Mercer made perfect scores. Captain J. Frank Meyer in a Ford drew 178 points, while L. M. Barr in a Peugeot was docked 1. On the losing side the clean scores were made by R. C. Cook in a Stearns-Knight and John D. O'Connor in a Buick. John A. Bell in a White and F. E. Sparks in an Oakland each drew 1 point. B. McSteele in a Scripps-Booth was the chief offender, drawing 222 points the first day.

Maxwell Dealers from Buffalo Region at Plant

DETROIT, MICH., Aug. 28.—Under the leadership of the Meyer Motor Co., Buffalo, distributor for the Maxwell cars in that city and vicinity, twenty-five dealers and sub-dealers from that territory came to the Maxwell plant this week to take delivery of their 1915 demonstrators. They were entertained by the Maxwell company at luncheon and were shown through the plant and given a talk about the new car and the company's selling campaign. The visitors returned to Buffalo by boat but took their new demonstrators with them and started for their home towns in them.

FORD Employs 9,031 Foreigners—A count was made recently among the workingmen at the Ford Motor Co., Detroit, Mich., to find out how many foreigners were employed and to what nationalities they belong. This resulted in finding that the 9,031 foreign workers belonged to twenty-two different nationalities. The Poles numbered 2,677; then came the Russians, 2,016; Roumanians, 750; Italians, 690; Germans, 606; Austrians, 388; English, 380; Syrians, 330; Hungarians, 269; Canadians, 226; Servians, 210; Irish, 148; Scotch, 133; Lithuanians, 73; French, 55; Hollanders or Dutch, 26; Danes, 21; Croatians, 13; Turks, 8; Belgians, 6; Japanese, 3; Australians, 3. Total, 9,031.

Entire Denby Organization in Plant—The entire organization of the Denby Motor Truck Co., Detroit, Mich., is now located at the plant, Dubois and Franklin streets. The general offices were up to the present in the Dime Bank Bldg.

Robie Co.'s Plant in York—The Robie Motor Car Co., which had temporary quarters with the Massnick-Phipps Mfg. Co., in Detroit, has moved to York, Pa., where it will manufacture a light car. No information has been given by the company, but an announcement is expected to be made within the next few weeks.

Mohawk Rubber's New Plant—A building permit has been granted to the Mohawk Rubber Co., Akron, O., for the construction of a $15,000 addition to its factory on Second avenue and River street. It is planned to construct another building of similar design and size during the Fall. Each of the buildings will be 100 by 61 feet and two stories high.

Wheel Plant for Rockton—The Great Northern Mfg. Co. organized to manufacture a new wheel for motor cars which will do away with the necessity of using pneumatic tires, has decided to build a factory at Rockton, a few miles south of Beloit, in Winnebago County, Ill.

Will Make Ford Tires—A new tire making concern is being organized in Toledo, O., and application for a charter will soon be made to the secretary of state. The concern will take for its name the Ford Tire Co., and will manufacture tires and tubes exclusively for Ford cars. It is said the company will be financed on the co-operative plan by Ford owners.

U. S. Truck Plant in Covington—For the purpose of taking over the United States Motor Truck Co., of Cincinnati, O., a new concern of that name was recently incorporated under the laws of Kentucky with an authorized capitalization of $25,000. The new company has located its plant in Covington, Ky., where it is turning out U. S. trucks in 2, 3 and 4-ton sizes. New 1 1-2-ton models will be announced shortly.

Additional Plant for Ball Bearings—Announcement has been made in Philadelphia that the Hess-Bright Mfg. Co. will add to its plant at Front street and Erie avenue in that city in view of the necessity put upon it by the war of manufacturing in this country ball bearings which have been manufactured heretofore in Germany. It is stated that plans have been made for the necessary additions and work will begin at once. Automatic machinery will be employed to the largest extent possible, the higher wage scale in this country furnishing a greater incentive to the use of such machinery than exists in Germany.

M. & M. Co. Enlarges—To take care of its increasing business the M. & M. Co., Cleveland, O., dealer in automobile supplies, has acquired addiitonal property and will erect a new plant. The M. & M. company of which J. C. McLean is general manager, recently took over the stock and good will of the Kinsey Mfg. Co., Toledo, maker of radiators and parts. This stock will be shipped to Cleveland to be disposed of.

Russell Co. May Add Men—The Russell Motor Car Co., Toronto, Ont., has announced its intention to keep its full staff on its books and is very optimistic regarding the stability of Canadian business. "We are endeavoring to keep every man employed, so that our workmen may not suffer to any considerable extent," said an official of the company, "We have no intention of laying off men or of closing down the works. We feel that Canadians will be fair enough to support a Canadian industry which at a time like this gives support to Canadian workmen." Both in the automobile and bicycle departments of their concern, the Russell company said that there has been no falling off in the number of orders and that they may have to hire additional men instead of discharging any. The company has enough work on hand, declared the official, to keep it busy for several months.

The Automobile Calendar

Sept. 4	Des Moines, Ia., Track Race, Iowa State Board of Agric.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

Delaware

WILMINGTON—Postles Automobile Brokerage Co.; capital, $50,000; to transact a motor car brokerage business. Incorporators: G. P. Postles, L. A. Braidley and S. D. Townsend, Jr.

Illinois

CHICAGO—Eagle Cycle Car Co., under Massachusetts laws; capital, $250,000; to manufacture motor cars. Incorporators: J. Parker, U. B. Curtis and E. G. Lancaster.

CHICAGO—Modern Auto Parts Co.; capital, $20,000; to manufacture motor cars, parts, gasoline engines and parts thereof. Incorporators: E. S. Carr, W. R. Fetzer and E. A. Biggs.

Massachusetts

SPRINGFIELD—Hendee Mfg. Sales Co.; capital, $50,000; to sell motorcycles, motor cars, aeroplanes, etc. Incorporators: G. M. Hendee, Suffield, Conn.; F. J. Weschler, Springfield.

Michigan

DETROIT—McKenney-Devlin Co.; capital, $10,000; to manufacture and sell motor cars. Incorporators: George A. and Lyle A. Devlin and Paul R. McKenney.

DETROIT—Stoepel Co.; capital, $1,000; to deal in motor cars and supplies. Incorporators: H. Robert Stoepel, David M. Whitney and Nathan T. Viger.

New Jersey

CLIFTON—Lubricating Accessories Co.; capital, $25,000; to manufacture motor cars and lubricating specialties. Incorporators: J. Swanson, R. W. Haubner and P. A. Ott, all of Clifton.

New York

JAMESTOWN—Gabrielson Car Parts Mfg. Co.; capital, $35,000; to manufacture motor car parts, etc. Incorporators: John Gabrielson, Gustaf A. Lawson and Oscar A. Lenna, all of Jamestown.

ROCHESTER—J. Lawrence Hill Co.; capital, $10,000; general motor car business. Incorporators: J. Lawrence Hill, 40 Warwick avenue; James Jaffray, 45 Richard street; Joshua C. Harris, 327 Webster avenue.

NEW YORK—Saxon Motor Co. of New York; capital, $1,000. Incorporators: Harry W. Ward, 1305 Bellevue avenue; Lincoln R. Scafe, 173 Clairmont avenue; Laurence Moore, 473 Jefferson avenue; all of Detroit, Mich.

SYRACUSE—Reo Sales Co.; capital, $15,000; general motor car business. Incorporators: George E. Norris, 136½ Furman street; Harold N. DeWitt, Camden; Charles H. Norris, 28 James street.

Ohio

MASSILLON—Wagner Auto Garage Co.; capital, $10,000; to deal in motor cars and operate a garage. Incorporators: C. W. Wagner, F. M. Lore, G. A. Siebaneller, C. A. Wendling and C. M. James.

Pennsylvania

HARRISBURG—Cummins Motor Car Co.; capital, $25,000; to deal in motor cars and operate garages. Incorporators: O. O. Cummins, T. Y. Gregg and H. R. Walker.

PITTSBURGH—Motor Square Auto Dealers' Co.; capital, $5,000; to deal in motor cars. Incorporators: William H. La Fountain, Frank P. Blackmore, Lovell M. Johnson, C. P. Galanot and Frank Nichol, all of Pittsburgh.

GARAGES AND ACCESSORIES

Indiana

FRANKLIN—Parr Auto Shoe Co.; capital, $10,000; motor car supplies. Incorporators: W. A. Parr, G. E. Parr and William Feathergill.

GARY—Fifth Avenue Garage; capital, $5,000; general garage business. Incorporators: William Sykes, Ralph Sykes and Carlisle Dorman.

INDIANAPOLIS—Garage Owners' Association of Indiana; to improve conditions relating to public garages. Incorporators: W. N. Mitchell, A. L. Mitchell and George Pfleger.

INDIANAPOLIS—St. Clair Taxicab Co.; capital, $2,000; to conduct a motor vehicle business. Incorporators: B. G. Schwankhaus, Roger Kinney and C. B. Miles.

New Jersey

PATERSON—New Jersey Motorbus Co.; capital, $50,000; to operate motor buses, hacks, cabs, etc. Incorporators: L. Cramer, Sr., L. Cramer, Jr., and J. J. Purce, all of Paterson.

New York

LONG ISLAND CITY—Astoria Auto Trucking Co.; capital, $3,000. Incorporators: Philip Silliman, 192 Purdy street; Christopher Straub, East Elmhurst, L. I.; E. W. Ryder, 104 Taylor street, Brooklyn.

NEW YORK—Accident-Proof Tire Co.; capital, $250,000; to manufacture and deal in Cumberland tire filler and other motor car accessories. Incorporators: Kerr F. Albertson, 54 Morningside drive; James O. Hodge, 878 E. 23d street; Carl W. Stuart, Oriental Hotel; all of Brooklyn.

YONKERS—Frank X. Smith; capital, $1,000; to manufacture and deal in tires and rubber goods. Incorporators: Frank X. Smith, 312 New Main street; C. W. Reynolds, 188 Wadsworth avenue, New York city; Thomas F. MacMahon, 1400 Broadway, New York city.

Ohio

CLEVELAND—Ot-to No Air Tire Co.; capital, $100,000; general rubber manufactures. Incorporators: Frederick V. Roesel, Wallace B. Ott, George M. Ott, George N. Gilmore and Charles H. Frank.

ELYRIA—I. T. S. Rubber Co.; capital, $100,000; to manufacture all kinds of rubber goods. Incorporators: J. G. Tirrford, A. G. Smith, C. H. Ingwer, William C. Smith and C. H. Lewis.

Oregon

PORTLAND—Interurban Autocar Co.; capital, $10,000; to conduct a passenger and freight line. Incorporators: W. E., Henry M. and Helen M. Williamson.

CHANGE OF NAME AND CAPITAL

Michigan

DETROIT, Benham Mfg. Co., from $45,000 to $65,000.

Missouri

ST. LOUIS, George C. Brinkman Motor Car Co., from $5,000 to $50,000.

Ohio

AKRON, Marathon Tire & Rubber Co., from $100,000 to $500,000.

COLUMBUS, Twyman Motor Car Co., from $30,000 to $10,000.

Accessories for the Automobilist

ELK Terminal—John B. Stam & Co., 1789 Broadway, New York City, is making a spark plug terminal, Fig. 1, unique in construction. The terminal is attached to the electrode by simply snapping the jaws over it. No solder or special tools are used in fastening the terminal to the wire yet a solid joint is made. About 1-2-inch of the high-tension cable is bared and this is thrust into the end of the terminal, which consists of a hollow screw. When this is screwed up the wire is clamped solidly in place.

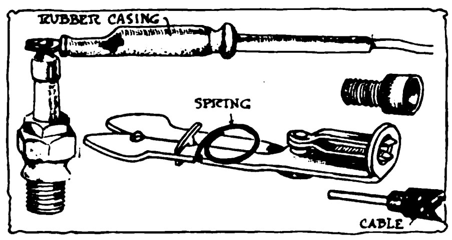

Fig. 1—Elk terminal. Right shows device assembled and at the left disassembled

Pneumatic Safety Clutch—Easy clutch engagement is automatically secured in the clutch, Fig. 2, manufactured by the Verges Mfg. Co., Fourth and Poplar streets, Milwaukee, Wis., by means of air displacement. It is a leather-faced, cone type which contains an air-chamber and a piston. When the clutch is released and the foot is removed from the pedal, the air resists the spring and will not permit the clutch to engage any faster than air is forced out of the chamber through the pet cock. The speed of engagement is regulated by the setting of this cock. Thus it is seen that it is impossible to make the clutch grab yet it is stated that the clutch engages rapidly enough for a quick start.

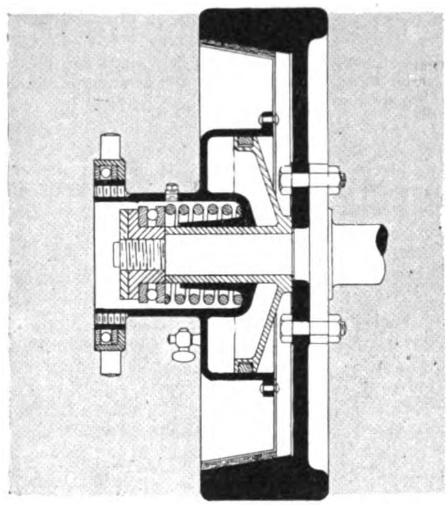

Fig. 2—Pneumatic safety clutch that cannot be made to grab

Clark Small Car Motor—A four-cylinder motor, Fig. 3, rated at 10-15 horsepower, and equipped with the motor, clutch and gearbox in unit, when desired, is manufactured by the Clark Engine & Boiler Co., Kalamazoo, Mich. The bore and stroke are 2.5 by 3.75 inches, giving a piston displacement of 74 cubic inches, which places the motor in the light car classification. The gearset is a two-speed and reverse sliding gear design.

The cylinders are cast in a block and are of the L-head type. The valves are fully inclosed and the push rods are adjustable. Access to the valves and piston heads is obtained by means of a detachable cylinder head. The valves are drop-forged, heat treated and ground to a close limit. Mushroom valve tappets, hardened and ground are employed and can be adjusted within .005 inch. The camshaft is a one-piece drop forging.

Two white metal bearings are used to support the crankshaft the one on the gear end being 1.625 by 2.5 inches, and on the flywheel end 1.625 by 3 inches. The crankpins are 1.625 by 1.875 inches. The gears are spirally cut to insure silence.

Ignition is supplied by a Schebler carbureter, and the Berling magneto is used. Constant-level splash lubrication has been adopted, the supply being maintained by a pump. All parts are hardened and ground and all bolts and studs are built according to the S. A. E. standard.

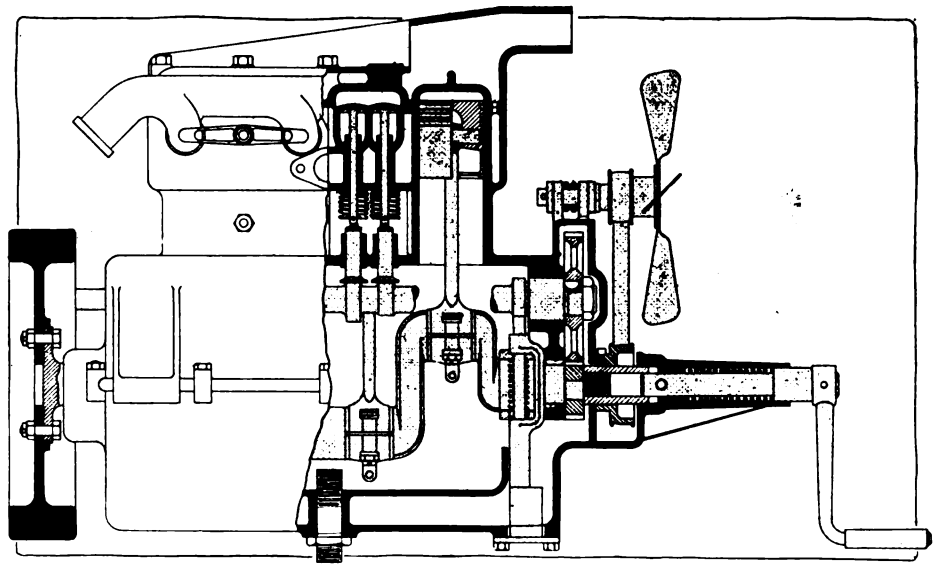

Fig. 3—Four-cylinder Clark motor of 10-15 horsepower. It can be equipped with clutch and gearset in unit when desired

Sangamo Ampere Hour Meter.—The Sangamo Electric Co., Springfield, Ill., is manufacturing a variety of types of ampere hour meters to meet the many conditions imposed by electric vehicle service, but in every case the meter consists essentially of a small electric motor device having the moving system completely immersed and floated in mercury, but with the containing chamber built in such a way that the mercury cannot be spilled. The revolutions of the little motor are proportional to the amount of current, taken from the battery or put into it from moment to moment, so that by recording the revolutions through a suitable clockwork dial, the ampere hours taken out or put into the battery can be shown as simply as the time is recorded by a clock.

The operating parts of the meter are enclosed in several forms of case. The one principally used on electrics has a dial large enough for easy reading. It is equipped with an aluminum base. The type generally used for a commercial vehicle service has an iron base with very heavy bottom connecting terminals.

The most highly developed type of ampere hour meter is that having the distant dial combined with a Weston ammeter.

The ammeter is useful on an electric vehicle to show the amount of current drawn at any time, thus indicating the condition of the tires, brakes, bearings, etc., and combined with the ampere hour meter the ammeter is a very useful instrument. Of the two, however, this concern claims, an ampere hour meter is more valuable, because a person driving an electric vehicle knows at any moment how much current has been taken from the battery and therefore the amount still available. Also, when charging, the ampere hour meter is the only device which will automatically give the necessary amount of overcharge for any type of battery, it is stated.

Swan Demountable Ford Bodies—Demountable coupe and limousine bodies, by means of which a Ford car can be converted from an open car into a closed one in 30 minutes are manufactured by the Swan Demountable Body Co., 4021 Payne avenue, Cleveland, O.

This type of body is placed directly over the touring body, making a cold and weather-proof construction. It is stated that it cannot rattle or squeak. The price of the limousine is $150 and the coupe body $90.

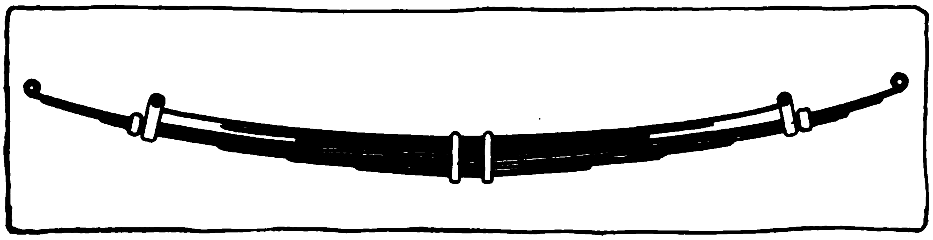

Fig. 4—Andersen auxiliary spring that is designed to carry light and heavy loads equally well

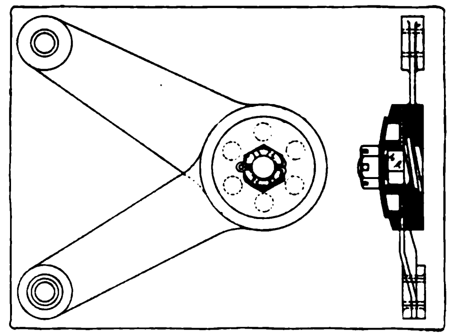

Fig. 5—La Porte shock absorber

Andersen Auxiliary Spring—A spring system is shown in Fig. 4 which, it is claimed will carry the light and heavy load equally well, that will take the light and heavy shock alike, that has scarcely any recoil, that needs no shock absorbers, and that is nearly unbreakable. The Andersen system is built in two sections; the lower consists of a light spring to carry the empty car only. The top section consists of a series of leaves built on the individual leaf plan, that is, every leaf is connected at the center but gradually separates toward the ends. This section is shorter than the lower section. From the end of the top leaf of the top section is a shackle which passes under the lower section. When the weight of the empty car is on the lower section there is no tension on the leaves of the top section. As you place the load in the car the lower section picks up the shackle which is fastened to the top leaf of the top section and engages as many leaves as is needed according to the load placed in the car. By this system if a five-passenger car has one passenger in it you have a five-passenger car with a one-passenger spring suspension. It is manufactured by the Andersen Spring Co., Detroit, Minn.

La Porte Shock Absorber—Charles La Porte, formerly chief engineer of the Aristos Co., New York City, has brought out a shock absorber that is designed to remain passive during the normal spring play and active only when required. This is the ideal action for a spring controller or shock absorber.

Referring to Fig. 5 it will be seen that this device is of the conventional scissors or V form, consisting of an upper and lower arm pivoted at the center. The top arm is machined to receive an acme threaded screw, which screw is worked in and out by the lower arm driving it. The action takes place when the screw, being turned radially, when the car springs close or open, thereby causes a lateral action of the two arms. On the down stroke of the car, the shock absorber has no effect on the springs, as the screw and nut move outwards, but on the rebound or opening of the springs, the screw and nut move towards each other, causing the lower arm, which slides on the screw, to move out against the rubber washer, which is held firmly by the outside nut, the amount of compression of this rubber deciding the resistance offered.

It can readily be seen that the slotted adjusting nut can set the pressure on the rubber washer to any amount desired. This feature permits any amount of normal spring action before bringing the device into its controlling action. This adjustment is made when applying on the car and need never be changed again, it is stated.

Buckeye De Luxe Shock Absorbers—For Ford cars only, the Buckeye De Luxe shock absorbers, Fig. 6, are of the well-known helical spring variety, but with the feature that perfect alignment with the car springs is obtained at all times by means of the knife-edge support of the spring seat. The spring seat is made of bronze. Two springs are used in each unit. The eye bolts are bushed. There are no holes to drill, and it is stated that anyone can attach them in an hour. A set of four is $15, and two, for either front or rear, are $8. The manufacturer is the Central Brass and Fixture Co., Springfield, O.

Universal Reel Light—A dash or gauge light and trouble lamp combined, which may be operated from any convenient source of current, is the Universal Reel Light, Fig. 7. Ordinarily it is used as a dash light, but when a trouble lamp is wanted, it may be detached from its case on the dash and the cord inside the case unreeled to any length up to 12 feet. When the cord is to be returned, it is wound up by means of a small handle on the front of the device.

By means of a ball and socket joint, the stem or handle which holds the light can be turned in any direction and may be fastened in any position by means of a small thumb nut. The reflector is also adjustable. It is made by Cummings Bros., Flint, Mich., and sells for $4.

Simplex Demountable Rim—Lightness is the particular feature claimed for the rim shown in Fig. 8. It will be noted that the rim is removed by backing up the bolts pinning it in place. Furthermore as there are no parts to be removed there are none to be lost on the road. No special tools are required, a monkey wrench being sufficient. It is stated that any type of demountable rim can be changed over into this type with little difficulty and small expense. The device is manufactured by the Simplex Demountable Rim Co., Milwaukee, Wis.

Krick Friction Transmission—The feature of the friction speed change, Fig. 9, manufactured by the Krick Co., East Fifty-fifth street and Dorchester avenue, Chicago, Ill., is the direct drive on high.

All the working parts are mounted on a steel frame which is attached to the vehicle frame by a three-point suspension, or rigid if desired, and the connection is made to the engine and the rear axle in the usual way.

The two friction wheels bear equally against the driving disc and on each side of the driving shaft. This does away with the side cramp which cannot be avoided with the single friction transmission and this with about one-half the applied pressure to the driving disc.

The two friction wheels slide on square shafts, with no keys to work loose or quickly wear out. All of the rotating parts are mounted on double row ball bearings of the self-aligning type. A special selected chrome nickel steel is used. The list price is $65.

Bryant Gearshift Lock—Due to a typographical error the price of the Bryant Gearshift lock made by the Bryant Sales Co., 422 Cuyahoga Building, Cleveland, O., was stated as $3, when $8 is the price, in the description which appeared in the August 20 issue on page 388.

VOL. XXXI NEW YORK—THURSDAY, SEPTEMBER 10, 1914—CHICAGO No. 11

The AUTOMOBILE

France's Automobile Industry Under Army Control

Many Plants Being Used for Making Trucks, Aeroplanes, Cannons, Bombs and Cartridges

Touring Car Production Nil—May Ask Repeal of Non-Export Rule —Belgian Factories Closed

By W. F. BRADLEY

Special Representative of the Automobile with the Allied Armies

PARIS, Aug. 26.—Inquiries in the various automobile factories around Paris show that the production of touring cars is absolutely nil. In many cases important orders are in hand and a sufficient staff has been left to put work through if only permission could be obtained to export.

May Revive Export Trade

Efforts are now being made to obtain from the Minister of War a repeal of the order forbidding the exportation of automobiles and automobile parts, at any rate so far as regards allied countries. It is believed that the reasonableness of this request will be seen and that within a very short time it will be possible to send cars to England, and from there to other parts of the world. If this release is given it will allow the hundreds of chassis which are at the present moment lying on dock sides and in railway depots to be taken out of the country. The railway companies now appear to be in a position to undertake the transportation of goods; even if they cannot be relied on, manufacturers appear to be willing to undertake their own transportation as far as the coast. Even with the law against exportation repealed the volume of business can only be a mere driblet of what it was a month ago, owing to the lack of men in the shops.

A few of the factories have been militarized. In this case the original staffs have been retained, but the men are under military rule and work under the control of army officers for the army. Among these are Gnome, making aeroplane motors; Anzani, on the same class of work, and the aeroplane motor department of the Renault factory. The Blum-Latil factory, in which numbers of four-wheel-drive tractors are produced, is under military rule.

De Dion Bouton is under military law, with 1,000 men working on trucks, automobile cannon, and also on special work for the military arsenal at Puteaux.

Motobloc at Bordeaux is militarized.

Berliet is under military rule with 300 men working on trucks. The factory will deliver 180 trucks by the end of August and 250 by the end of September.

The Mors factory was militarized for a short time, but is no longer working for the army.

Saurer Busy Making Trucks

In addition to those firms directly responsible to the army authorities, several are working exclusively on army orders. Thus Saurer has been able to maintain a staff of 200 out of 800, which will be increased shortly to 400 or 450, all the men working on trucks or spare parts. This firm has 800 trucks on the fighting line.

Panhard is working almost exclusively for the army and navy making trucks and war supplies.

Renault has stopped the production of touring cars and is building trucks for the war department.

Peugeot has been able to keep all three factories open with very reduced staffs, the work done being for the army. Robert Peugeot is serving as a lieutenant in an artillery regiment at the front.

The Mercedes repair shops near Paris have been taken over by the war department and are used as an extension to the military arsenal at Puteaux. The stock of finished cars at the firm's showrooms in Paris has been requisitioned for army service.

Bayard-Clement is working with 150 instead of 1,500 men, all of them engaged on airships and trucks.

Making Bombs in Alda Plant

Delaunay-Belleville is doing nothing but military work, this including material for the artillery service. Instead of cars bombs are being manufactured in the Alda factory.

Alcyon has closed down all but its motorcycle department.

Delahaye has had its commercial vehicle section militarized.

All other factories appear to be closed entirely or are merely keeping the spare parts department going. The Unic people have kept on 200 men, who are producing for stock, the company having a sufficient number of orders in hand to expect a quick release when peace is declared.

The Darracq big erecting shop has been turned over to the war department and is now used for making cartridges. Only the spare parts department is running. Most of the foremen have been returned from the war, the authorities having more men than they need, but workmen and supplies are not obtainable.

Charron, Vinot, Dietrich, Delage, Hispano-Suiza, are all closed.

Brasier is working with one-quarter of the original staff, but having received army orders will take on more men shortly.

Belgian Factories All Closed

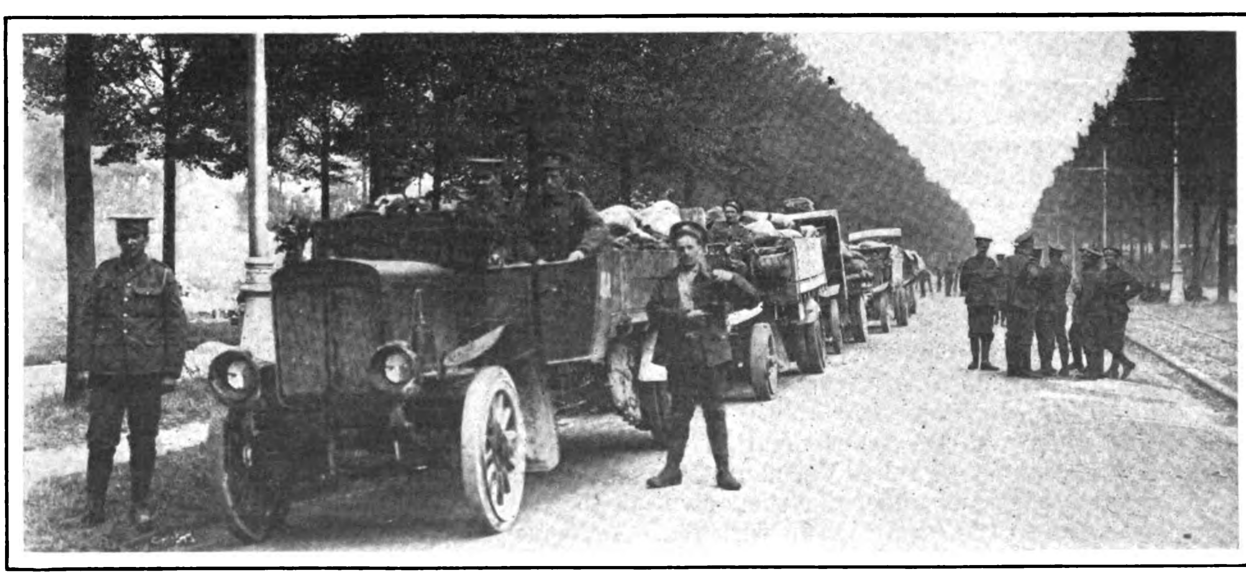
Although little news is available, it may be taken that not a single automobile factory is working in Belgium. The most important works are Minerva, Excelsior, Pipe, Nagant, Herstal at Liege, and the Derihon works, where the B.N.D. steel is produced. The Derihon factory is close to one of the forts on the outskirts of Liege, where the most desperate fighting has taken place. No news has been obtainable of the fate of the works, which contain most valuable machinery, and it is feared that they must have suffered very severely. The Derihon brothers have a second factory on the French side of the frontier, which up to the present has escaped injury.

Trying to Capture Herstal

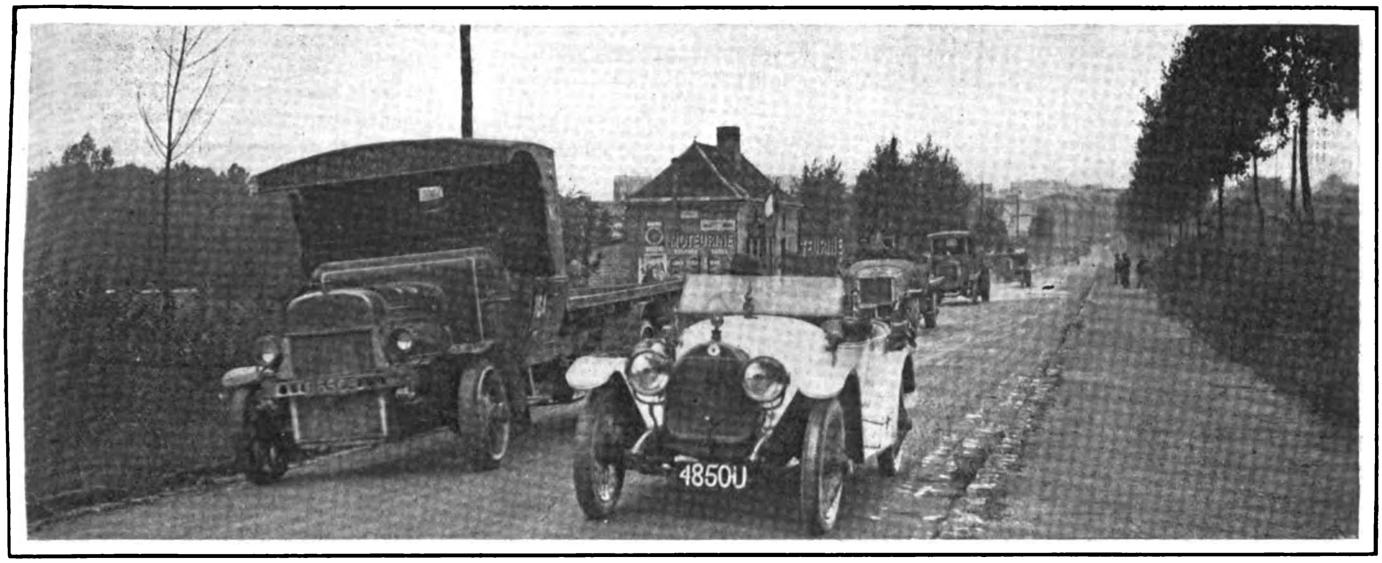
Herstal is also the small arms factory of Belgium. It is known that the Germans made a determined attempt to capture this, but when the last news came through they had not been successful.

No European Automobile Shows This Year

PARIS, Aug. 31—It may safely be assumed that there will be no automobile shows in Europe this year, even if the war is of short duration. Under the most favorable circumstances they could not be held until the early months of 1915, but the probabilities are that they will all be abolished. No official decision has been taken in Paris, for it is impossible to get together the committees responsible for the exhibition. Henri Cezanne, general manager of the Paris show, and also secretary of the Chambre Syndicale des Constructeurs d'Automobiles, is at the seat of war. Louis Renault, the president of this syndicate, is in Paris.



A convoy of British motor trucks with the English troops in France ready to start for the front. It is estimated that there are from 2,500 to 3,000 British moter trucks in service with the army. The trucks move in convoys of from six to a dozen, each convoy being accompanied by an officer in a touring car who sets the pace and a number of motorcyclists who keep full control over the convoy. The trucks used in the English army are mainly requisitioned among truck users and manufacturers as the English subsidy system has not as yet been developed very fully and the result is little uniformity and even inadequate equipment



A touring car passing British army motor trucks on the road near the frontier of the allied army in France

British Trucks with Army in France

Number in Service Estimated at 2,500 to 3,000—Vehicles Move in Convoys of Six to a Dozen—No Uniformity

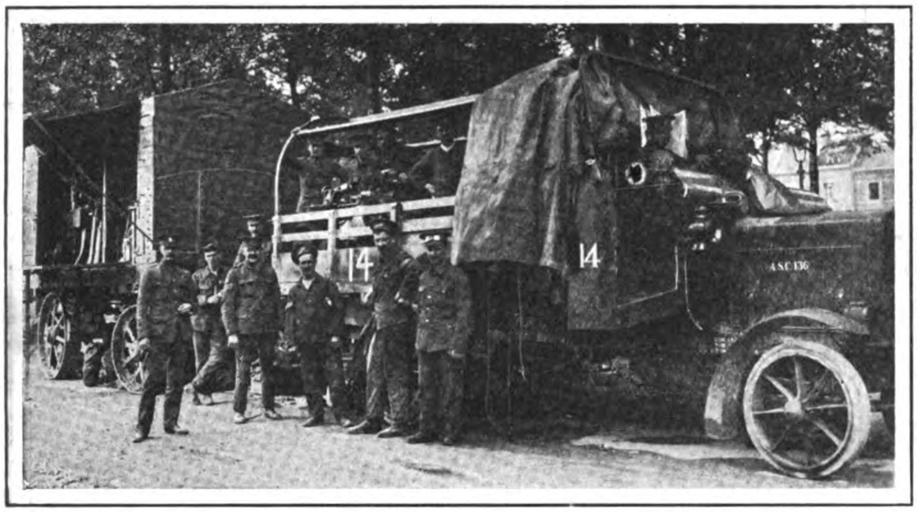
By W. F. BRADLEY

PARIS, Aug. 26.—For the first time in 100 years a great British army is operating on Continental Europe. It is recognized on all hands that the work of mobilizing the troops, carrying them across the intervening sea and moving them up to the fighting line has been a marvel of organization and precision. The work was done, too, with such secrecy that it is doubtful if a single person in Germany knew of it until the newspapers announced it officially on its completion.

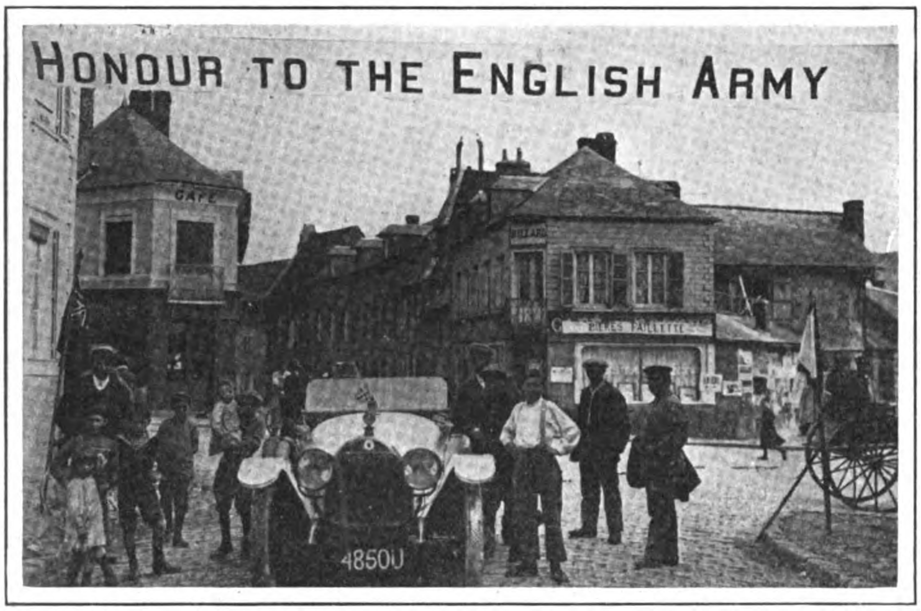
Motor vehicles have played an important part in this work. England is peculiarly situated. Being a small, thickly populated country, with closely set towns and a network of railways, it has never been necessary for her to develop an army motor system for work at home. The possibilities of military operations abroad were so remote and of such an unknown nature that it was difficult to decide what form to give to mechanical traction. In this connection she was quite at a disadvantage compared with France. This latter country knew where war was likely to be declared, could build its army lorries and other motor vehicles to suit those geographical conditions, and could even test them on the possible seat of war.

I have just been able to get in touch with the English army in the field, and particularly to examine the work of the motor corps. With regard to the movement of officers, it should be noted that they never travel by train, notwithstanding the fact that the whole railroad system of France is at the present time in the hands of the military authorities. All journeys from the fighting line to the base, and all trips from the front to the War Office, in London are done by automobile. English troops land at Boulogne, Dieppe and Havre; the headquarters staff is on the Belgian frontier—or rather is at the present moment; where it will be when this matter appears in print is another question. The distances are from 130 to 180 miles. Thus by the use of fast cars officers landing at any of these ports can be with the headquarters staff within 4 hours. In the great majority of cases English cars are being used for this work. I came across a few American cars, which had evidently been requisitioned, their driv-

An army officer's car and a subsidized motor truck traversing a grade crossing in France



One of the trucks with the English army in France. Behind it is a motor workshop



How the French villagers greeted English troops on their arrival on French soil

ers having volunteered with the cars. Not only are the roads most suitable for high speed, but there is no traffic other than that of military officers. In a trip of 400 or 500 miles I did not see more than a dozen cars which were not on military service.

It is estimated that there are at the present time 145,000 British troops in operation against the German forces. The number of motor trucks in service is not known with accuracy, but may be estimated at 2,500 to 3,000. This, of course, excludes touring cars. The automobiles were brought from various English ports: Liverpool, Bristol, Cardiff, Portsmouth, Southampton, Folkestone, and were landed at Havre or Boulogne, or in some cases were brought up the River Seine to Rouen. From this point they traveled east under their own power to the main supply depots at the back of the British army.

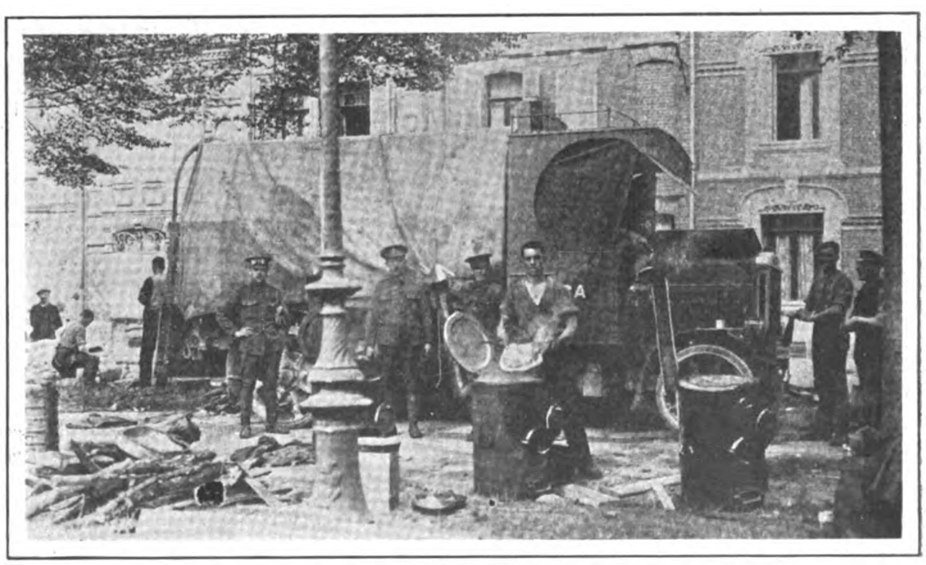
Nearly all the supplies are brought up from the ports to the central depots by means of the railroad. One of the most important of these depots is Amiens, about 65 miles from the present fighting line. Here there are about 1,500 motor lorries engaged in the task of carrying provisions and ammunition daily from the base to the front. It is not less than a 6-hour journey. The vehicles can make the round trip in a day, then spend the second day in loading up and verifying the condition of the vehicles. On the morning of the third day the same trucks are ready to start out again for the journey to the front.

Paced by Touring Cars

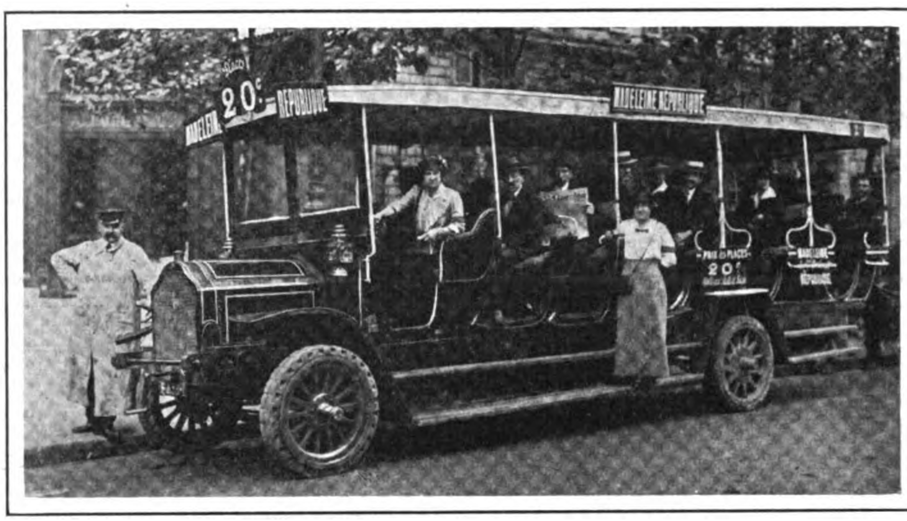
The method of operation is for trucks to move out in convoys of from six to a dozen, each convoy being accompanied by an officer in a touring car, who always keeps at the head of the procession and sets the pace, and by a number of motorcyclists. One or two of the motorcycle riders survey the road ahead and a couple bring up the rear.

As the British army owns but a small number of motor trucks and has not developed its subsidy system very far beyond the paper stage, it has to rely principally on requisitions among motor truck users and what manufacturers' stocks are available. This is the weak feature of the system. Although the individual vehicles may be good, they are of such diversified types that they are not suitable for working together in convoy formation. There are exceptions. Thus, on one of the roads leading to the frontier I came upon a splendid convoy of sixteen Daimler 5-ton trucks carrying ammunition. All the vehicles were alike and moved along with as much regularity as if they were all linked together.

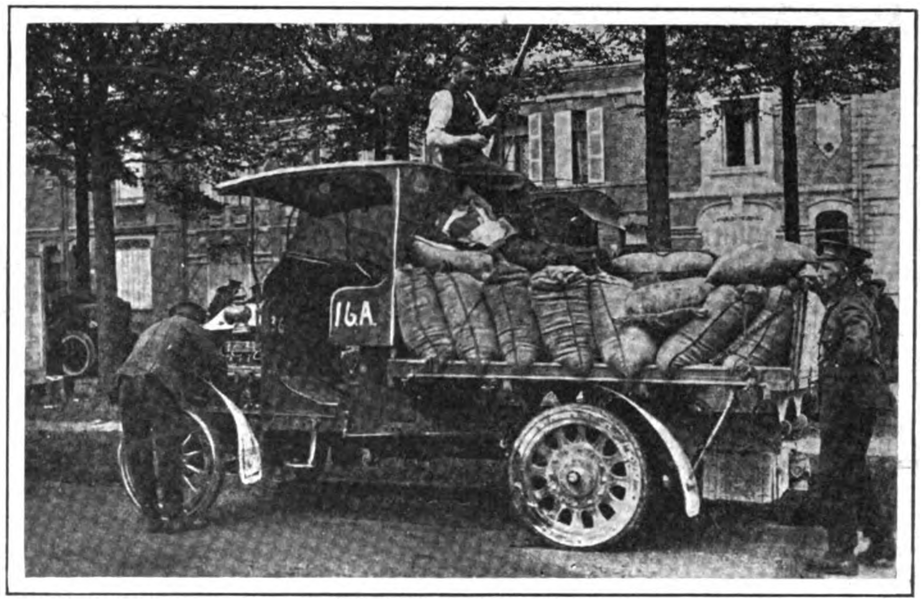
There were other convoys on the road with as many different makes as units, and with speed abilities varying from 7 to 17 miles an hour. Not only were they of different makes, but the bodies were of all kinds, for the trucks had been taken direct from private service, without even removing the ad-



English open-air kitchen at the army headquarters at Amiens, France vertising matter that was on them. While it was possible to keep up a certain speed on the level, as soon as hills had to be negotiated the slower vehicles and the defective ones dropped back, thus delaying the entire convoy. Hilly country also necessitated passing and repassing, which, of course, was an element of danger. Not a few radiators were smashed owing to cars running backwards on the hills through being unprovided with sprags. With a closely placed procession, a rear movement of a few feet would be enough to cause an accident. These defects were known to the officers in charge of the motor service, but, of course, there was no time to remedy them when war had been declared.



All Paris motor buses being at the war, this type of vehicle has been put into service. It runs on the main boulevards and has a woman conductor



One of the requisitioned motor trucks with the English troops in France

The French authorities have worked on this problem a sufficient length of time to have created what may be termed a model type truck in all the factories. Although these vehicles differ considerably in design, they are uniform in power, size, speed, load-carrying capacity, body, clearance, tire sizes, and in such details as sprag, towing hooks, radiator guard, magneto and carbureter.

Touring Cars Do Well

While traveling over French roads I have been able to see the strong and the weak points of the English motor service. Touring cars are giving very little trouble, despite the hard work and rough usage they are receiving. In 3 days' constant driving I saw two breakdowns, and one of these was repairable. Where the trucks were manufacturers' stock, the service was also excellent and serious breakdowns almost unknown. But where trucks had come out of private service and were set to work together with little discrimination, there was plenty of material for the repairman. On one stretch of road over which several hundred trucks had passed cripples were to be found every 2 miles. The story was the same in every case: the vehicles were satisfactory for service at home on well-paved city streets, but when they were put on the open road in company with more powerful and faster units they had to be pushed to the limit and the lubrication or cooling system became inadequate.

A fine fleet of Daimler trucks all loaded with ammunition on their way to the fighting line

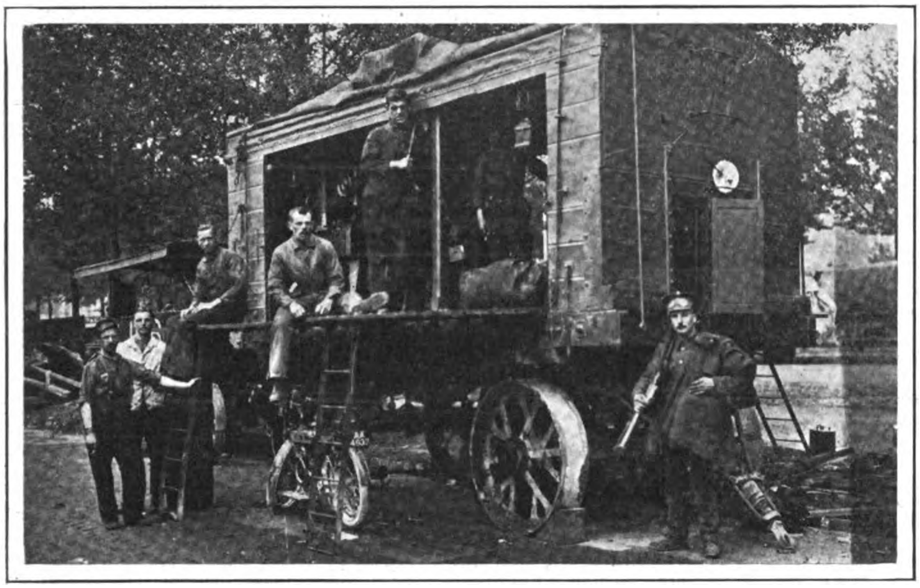
Motor Supplies from England

All supplies necessary for the British motor fleet have been brought from England. These include supplies of gasoline and oil. Thus although the trucks are at present working in a friendly country, they do not have to call upon the resources of that country. This is particularly important as regards the fuel supply, for although there is no shortage at present in France, the presence of a few thousand English vehicles requiring to be fed would have been an important matter. The general arrangements as regards the supplies not only for the motors but for the entire army, show the working of some master mind.

French War Trucks Superior to English

England Has More Vehicles But Lack of Uniformity and Preparation for Service Impairs Their Value

By W. F. BRADLEY



One of the British army motor workshops with the troops in France

FRANCE and England, fighting side by side against Germany, are both making extensive use of motor transportation for the feeding of their armies, the supplying of ammunition, and the removal of wounded. The governments of both countries have the power, in such times as the present, to requisition all types of motor vehicles, and both have made use of this power to the full.

Here the similarity between the Allies comes to an end. It is not a question of development of the commercial vehicle industry in the respective countries, or of the technical value of French and British vehicles, but of the adaptability of the vehicles as a whole to military purposes. In actual numbers of commercial motor vehicles in use, England is undoubtedly ahead of France; in technical development she is not inferior, but in the application of her fleets of motor lorries to military uses she is on quite a different plane from France. This is clearly seen now that the two nations are working side by side.

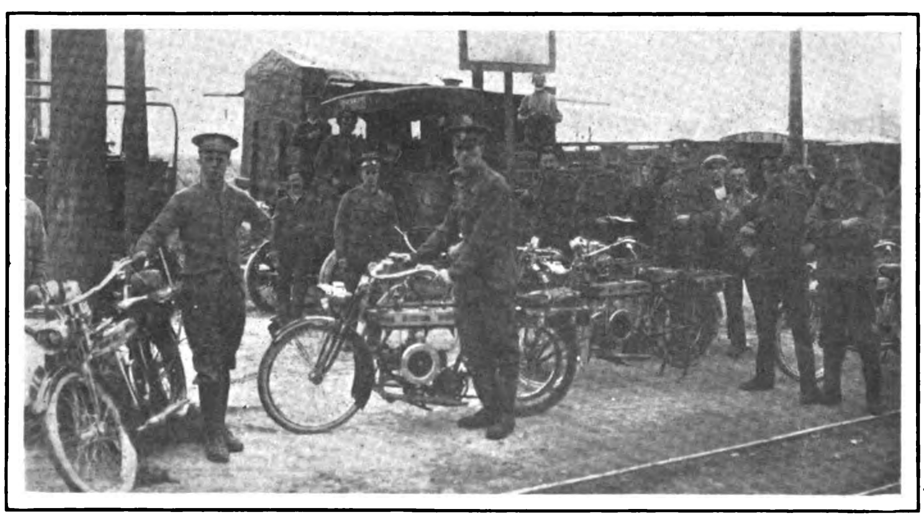
British Requirements

It is necessary to go back a considerable distance to understand the differences. England has developed motor transportation on purely commercial lines; she has developed it thoroughly, with a view only to the needs of the commercial user. When the British War Office became alive to the value of motor transportation, it had to deal with a well developed and highly specialized industry, the heads of which had been seeking to give the best possible value to the commercial user, unhampered by any consideration of military requirements. At a rather late date the War Office instituted a subsidy system and issued its own specification for army types. Manufacturers had to build to this specification, whether it was in accordance with their own technical program or not; they had to submit these subsidy types to special army tests, and finally had to convince purchasers that these new models were superior to the others.

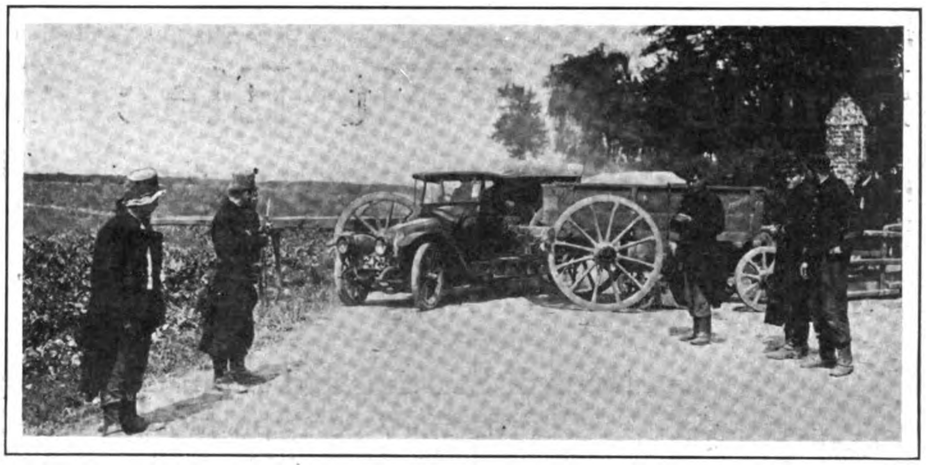
In itself the army specification was not unreasonable. It was based on the Leyland chassis, a vehicle which had given excellent service. But it practically said to manufacturers: "You must abandon your own design, however good it may be, and accept ours." It said to users: "If you want the subsidy you must do without the detail features you consider necessary for your particular trade, and accept our type of vehicle." Under the circumstances it was hardly surprising that the British subsidy scheme failed to arouse any enthusiasm and in many quarters met with opposition. As proof of the indifference with which it was received, the last British army trials united three vehicles. The last French army trials had 110 trucks.

France's Preparation

The history in France has been entirely different. At a very early stage, in fact before commercial vehicles were a commercial success, the army was interested in them and sought to adapt them to their own use. Under the subsidy scheme, which has now been in application about 8 years, the regulations were of such a nature that practically every manufacturer was able to enter



Motorcyclists attached to the British army motor corps in France with the types he then possessed. Unlike the English scheme, there was no preference for bevel drive over worm or chains, for a particular type or position of motor, or for a certain class of gearbox. The field was even left open to steam, gasoline, and gasoline-electric. All that was required at first was that the trucks should be capable of doing good work on the road individually and collectively. Year by year the regulations and tests became more stringent, without, however, interfering with general design. The result has been that throughout France there has developed a type of vehicle of a uniform size, power, weight, speed, body, clearance, etc. In other words, the whole of the French construction has given military requirements prior consideration. The result is that when the war broke out practically all the best trucks in France were subsidized types, whether the owners were drawing the subsidy or not. Evene at this early stage of the war the French system has justified itself. It has been shown that it is much more important that a dozen vehicles from a dozen factories should be able to travel together over varied country at a given speed than that they should have the same design of crankcase or the same diameter crankshaft. Some of the features on which the army has insisted, and which are generally of little importance to the private user, have found their justification in actual war service. They are the use of sprags, efficient clearance, radiator guards, uniform bodies, towing hooks front and rear, three fuel carbureters, and tanks allowing a big range of action.



All Belgian roads are barricaded in this manner to facilitate arrest of spies. Cars can pass through only at a walking pace

Special Provisions

In a few cases the British Army Service Corps has made arrangements to bring material direct from the ports to the fighting line. This appears to apply mostly to ammunition. It is at present too early to note what arrangements have been made by the English army for the use of trucks in carrying wounded soldiers away from the front Their vehicles do not appear to be capable of taking stretchers, and thus will practically be empty on return journeys. The French subsidy trucks, on the other hand, have a uniform type of body consisting of a platform with stout hoops over which a canvas cover is placed. The hoops have to be of sufficient strength to receive stretchers and wounded men; whenever there are men to be taken away the trucks are made use of for this purpose. If the English system is different from the French, it is because the medical service organization of the two armies is not the same. The English Medical Service Corps is equipped for the removal of wounded, and does not dovetail with the Army Service Corps.

Complete Motor Workshops

Each division has three or four motor workshops, which are kept in the open air garage at the depot town. At Amiens, where there were 1,500 automobile trucks, there were four workshops. These consist of a heavily built high-wheeled van with sides which can be hinged to open outwards so as to increase the floorspace. The roof is made to open and is covered by a waterproof canvas blind on rollers, serving to make the sides waterproof when the whole vehicle is closed up, or spreading out as a sunshade. The truck is drawn by a steam tractor. It is completely fitted with machine tools, lathe, forge, drills, saws, etc., and obtains its power from a single cylinder motor placed on the ground under the workshop and having belt connection through the floor. The French workshop is smaller, for it is an automobile chassis with a workshop body, the motor serving both to drive the vehicle and to operate the machinery.

A number of steam tractors have been brought over with the English army. Each one hauls a couple of trailers. The steam trucks are impractical for active work, however.

Finds 12-Volt Electrical System Superior to 6-Volt

The Automobile Engineers' Forum

Engineer of Starting and Lighting System Manufacturer Claims 12-Volt Type Is Lighter, More Efficient and Easier to Install

NIAGARA FALLS, N. Y.—Editor THE AUTOMOBILE—Our experience with starting and lighting systems of different voltages has proved conclusively that the 12-volt is superior to the 6-volt system. We find it to be lighter, easier to install, more efficient, and to give better service.

Weight of 12-Volt System Is Less

The weight of a 12-volt starting motor is much less than a 6-volt motor designed to operate at the same speed, and to give the same torque. This is especially true in the case of a single unit system, that is, a combined motor and generator. There is also a saving in size and weight of the starting switch and wiring, which more than compensates for the difference in weight between a 12- and 6-volt battery.

The 12-volt system is easier to install, due to the greater flexibility of the smaller size of cable used, and to the reduction, in size of all accessory parts, such as switches, terminal posts and lugs.

The efficiency of both the motor and the generator is higher with a 12-volt system. The heavy current required by a 6-volt motor results in large losses in the wiring, switch contacts and brushes. The efficiency of the motor is thereby reduced and the cranking speed is cut down to such a low point that it is difficult to start on the magneto. In a 6-volt generator the brush contact and friction losses are much greater than in a 12-volt machine and consequently more power is required from the engine. In Europe, where fuel consumption is a very important factor, it is significant that 12 volts is the standard lighting voltage, and there the question of starting has never been seriously considered until very recently.

In service the car owners using 12-volt systems find that they have less trouble in keeping generators in operation, as dirty commutators do not interfere with the building up of voltage. The increased pressure is sufficient to overcome the resistance. The brushes have a longer life, saving trouble and expense of renewal. The 12- or 14-volt lamp that is now manufactured is as durable and strong as the service demands. Even higher voltage lamps are giving excellent service. Automobile electric lighting has become so universal that there no longer is the argument that nothing but a 6-volt lamp can be readily purchased.

12-Volt Systems Give Less Trouble

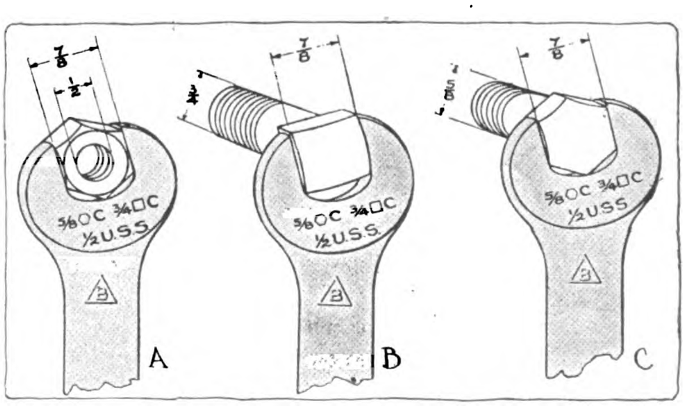
Together with the above advantages the 12-volt system permits the use of everything favoring simplicity in number and size of units, and in wiring. It is the best compromise between the advocates of high and low voltage and its more general adoption would do more than any other one thing to standardize the electrical system.—T. R. DU BOIS, starter department, United States Light and Heating Co.

In Ordering Wrenches Mention Number and Style of Finish

HARTFORD, CONN.—Editor THE AUTOMOBILE:—When a customer orders a wrench he probably wants it at the time of ordering, and wishes it to be delivered immediately. Under these conditions, if the dealer makes prompt delivery he will have pleased a customer who will remember where he can get his orders filled quickly. If the dealer is unable to fill the order by return mail because his customer has neglected to plainly specify what is wanted, everybody is sore on account of the delay, and trouble and expense is incurred by the necessity of writing to get complete specifications.

These same conditions often exist between the dealer and the manufacturer; that is, the delay in filling an order is caused by incorrect or incomplete specifications. The buyer has failed to make clear just what is wanted.

There are only two things necessary to specify when ordering drop forged wrenches, viz.: the number of the wrench and style of finish. However, it often happens that a customer has no catalogue handy and therefore tries to make clear his requirements by stating for what purpose the wrench is required. This is all right if the statement is properly and clearly put, which often times is not the case. For example—it often happens that the manufacturer gets an order for a wrench to take a ½-inch nut and fills the order accordingly with the result that he is asked to replace the



Illustrating several of the ways in which a wrench may be ordered wrongly. For instance, people often order a wrench to take a half-inch nut when they mean a nut with a half-inch opening. Square and hexagonal heads are also complicating features wrench with one that has a ½-inch opening to take the nut.

Nuts are designated by the size of the tapped hole, or the size of the bolt on which they are used. Bolts and cap screws are designated by the size of the diameter of body or shank of same, therefore a half-inch U. S. standard hexagon nut requires a wrench with an opening measuring ⅞-inch.

Standard lists of drop forged wrenches, as a rule, cover three styles of finish, namely: Unfinished, Semi-Finished and Finished, and prices vary according to the style of finish required. Therefore, it is essential that an order should plainly state the style of finish wanted.

The head or heads of wrenches are stamped so as to show for what purpose the wrench can be used, according to our system.

For example, if the wrench is for a 3/16-inch U. S. Standard nut or bolt, the opening measures 13/32 inch, and the head is stamped "3/16 U. S. S."

If the wrench is for a ¾-inch hexagon cap screw, the opening measures 1 inch and the head is stamped "¾ C." If the opening of the wrench measures ⅞ inch, the head is stamped "⅝ ○ C, ¾ □ C, ½ U. S. S.," showing that the wrench can be used for ⅝-inch hexagon cap screw or ¾-inch square cap screw, or a 1-inch U. S. Standard nut or bolt. Also, a ⅜-inch opening is stamped "⅜ set, 3/16 ○ C, ¼ □ C," showing that the wrench will take a ⅜-inch set screw, a 3/16-inch hexagon cap screw, or a ¼-inch square cap screw.

Thinks Over-Standardization in Car Design Means Stagnation

NEW YORK CITY.—Editor THE AUTOMOBILE:—Information is wanted on W. A. Swan's automo pill. Mr. Swan wants everything standard; but does he realize that that is to spell stagnation, but in another way?

It is not fair to say that the U. S. government is throwing away money when testing alcohol as fuel; it is now at least conclusively proven that alcohol as fuel is too high in price for a long time to come. Mr. Swan will have a self-starting motor. Why tantalize us, Mr. Swan, you probably know how to produce such a motor? To the rest of us it seems to be an impossibility, at least when clutches are not to be used, or their equivalent. Gears are not going to be used either; but are you not a bit behind the times there? There are no difficulties in the way of running cars without a gearbox; a larger motor will do that nicely, but the trouble is that such an engine becomes very heavy, costly, and will use a great deal of fuel, since it will be but seldom called upon to extend itself to its full capacity.

A Constantly Economical Motor

Strange to say, all things are best under but one condition and to produce a motor that will be equally economical under all conditions, that alone, Mr. Swan, will be a feat worthy of your best efforts. I am surprised to hear that when I thought it was well understood that of all the gear systems the internal gear was the least efficient. There is no difficulty either to drive each wheel independently; but, again, you must have excessively heavy motors to do so, else two sets of gearboxes and gears you do not want.

No carburetor, no radiator, no camshaft, and the motor still not to be a 2 cycle, i.e., a 4 cycle then. The only tangible thing standing out is that the motor will be a modification of the Knight type. The motor is probably not cooled at all.

And the fuel comes in pills. The pill idea is wonderful, but how about going up a hill? Big pills for big hills and little pills for little hills? The prophetic eye sees boxes with pills distributed by parcel post.—B. H. BRITT.

Recent Decisions of the Courts

Explosion Not Gasoline Dealer's Fault

By George F. Kaiser

A GASOLINE dealer was recently held blameless by the Supreme Court of Tennessee for an explosion which occurred while a gasoline tank was being filled.

In this case a father told his 17-year old son to take his automobile around to a drug store and have the gasoline tank filled. The son drove to the store after dark, stopped his car, gave an order for gasoline, turned down the rear light and walked off a short distance to talk to some boys. The tank was hung in the rear of the car and was about 24 inches above the tail lamp, which was lighted and had two glass sides but a metal rear through which the light did not show. Before going away the son turned the tail lamp down very low. The drug clerk brought out a 5-gallon can of gasoline and, not noticing the light, started to fill the tank, from which the cap had been removed. After he had poured in about 1 gallon the vapor reached the lighted lamp and an explosion resulted which injured the car. The owner thereupon sued the dealer for the damages but the Court held that the clerk had the right to assume that the son had put the car in a proper condition to receive the charge of gasoline and that the boy should have extinguished the light instead of turning it down, or else should have stayed by the car and warned the clerk instead of walking away. Judgment was therefore rendered in favor of the dealer.—*Grigsby & Co. vs. Bratton*, 163 *S. W.* (*Tennessee*) 804.

Bicycle Against Automobile

Where a bicyclist tries to shoot across in front of an automobile, he cannot sue and get damages from the motorist for his injuries, says Maine Court.

A bicyclist sued a motorist for injuries received in a collision between his bicycle and a motor car. He recovered a judgment of $39.55. The motorist carried the case to a higher Court and succeeded in having the bicyclist's case dismissed. The automobile was on the right side of the street and the bicycle was coming along in the opposite direction. There were lights on the automobile but none on the bicycle.

The Court held that, as the bicyclist wanted to "shoot right across to get clear of the automobile" when he could have turned the other way and gone behind the motor car, he himself was so guilty of negligence as to make a dismissal of his case proper.—*Robischaud vs. Spence*, 90 Atl. (Maine) 430.

Trolley Smashes Automobile

Minnesota Court says that a motorist cannot get back the money he spends repairing his car when it is smashed by a trolley if he does not stop on seeing the car 10 ft. away.

A motorist sued a Trolley Company to recover back the money he had paid for repairs to his car, which was damaged in a collision with a trolley. He testified that as he came to a crossing he looked for a trolley and the way was clear when he was 35 ft. away. When he was within 10 feet of the track he looked again and a car was "right on top of him." He turned to the right, pulled his clutch and put on his brakes but was hit.

The Court said that, as the motorist could have stopped his car but instead went on and took a chance, he was guilty of contributory negligence and could not recover.—*Batroot vs. St. Paul City R. R. Co.*, 146 N. W. 1107.

The Rostrum

Two-Stroke Cycle Ideal

EDITOR THE AUTOMOBILE:—The opinions of various readers, and some thinkers, on the two-stroke cycle is certainly an interesting feature of your magazine. A few ideas from another source may help those who are so fascinated with the valve or no valve problem as I am. When a traveler finds himself lost in a bewildering region and every trail leads to an unknown country, wisdom bids him retrace his steps to the fork of the roads on the mountain. Let us, also, go back to that fork on the mountain. At our feet lies the empire of the heat engine—to the east, the reciprocating engine is all-powerful; while to the west the Turbine kingdom lies. The light of knowledge has already risen on the east, so let our journey lie there. Whatever may be the thermodynamic cycle chosen, both four-stroke and two-stroke mechanical cycles can be invented to accomplish it. Wisdom again says, "Take the road of the two-stroke cycle, for it has the inherent advantages of simplicity and doubled power output." That these ideal features have not been successfully realized is a serious charge against our most capable engineers, who have spent time in developing the four-stroke cycle engine. I will say nothing about the numerous forks further down the road. I do say, however, that a mountain must be blasted—the volumetric efficiency must be greatly increased. The low volumetric efficiency and the fuel extravagance of the two-cycle are the results of poor design and the poorer inventive ability. Both conditions will be bettered by the same design. When the engineer breaks through to this region, he will see wonders of which we have never dreamed; torque as smooth as that of an electric motor; efficiency greater than that of a Diesel engine; silence made absolute and vibration wholly eliminated; weight reduced to a pound a horsepower. Being a mere man, he blinks his eyes and steps on his own foot—can he be in the land of the reciprocating engine—is this not the country of the turbine? My friends, he can believe his eyes and so will you very shortly. It can be done, it has been done, and without a make-up, too.

Providence, R. I. H. A. B.

Magneto Causes Miss

Editor THE AUTOMOBILE:—1—I have a car which starts badly. It has a four-cylinder, 4.25 by 5.5-inch motor, but only a magneto for ignition. It has not troubled me this way until recently. At the beginning I could start the motor with but a turn or two of the crank at any time. The motor works evenly and has lots of power when once under way. If it can be started rolling down a grade and then thrown into gear it starts readily enough. The carbureter adjustments have been changed, but the motor works so well it seems impossible that the trouble could be there. I use the dash adjustment for starting, but it does not help matters. Can you tell me the cause of this and suggest a remedy?

Canton, N. Y. H. S. S.

—Your magneto is probably causing the trouble, although it is well to make sure that the difficulty does not lie in the carbureter adjustment or is not due to leaky valves.

See that the spark plugs points are 1-32 inch apart, that all connections are tight, and that there are no short circuits. Then examine the breaker points on the magneto. File them until they meet squarely and then adjust them until the motor runs evenly at all speeds. The exact distance depends upon the magneto, but should be somewhere between 1/32 and 1/64 inch. If the points are too far apart the motor will not start or will miss at slow speeds, while if the points are too near together it will miss at high speeds. There is also a chance that the magnets are weak. If this is the case, there still will be difficulty in obtaining a spark at low motor speeds. Make sure that all the brushes are making good contact.

It is well to note that starting on the magneto will be facilitated by advancing the spark nearly all the way.

Cost of Raceabout Body Is $100

Editor THE AUTOMOBILE:—1—Could you advise me in the Rostrum how to cut down a model 34, 1912 Buick runabout, "A la Mercer"? Give a sketch if convenient.

2—What is the estimated cost of this car?

New York City. G. F. K.

—1—Fig. 1 shows how this car should look after being remodeled. The dash is slanted slightly, the bucket seats are placed directly on the frame and the gasoline and oil tanks, and tires are carried in the rear as shown. The steering post is dropped so that it will be in reach with the lower seat position. This is accomplished by loosening up the dash bracket that holds the steering column.

If you also desire to increase the speed of the car you should follow the directions given in the issue for August 27 in the Rostrum on page 406.

2—The cost will be anything from $100 up, depending on how well the body is finished and who does the work. It would be best to obtain estimates from several body builders.

New Use for Old Shoes

Editor THE AUTOMOBILE:—I have seen the idea advanced that when tires are rim cut and the treads are still good that the bead could be taken off and the remaining tire fitted over the casing of a good tire while deflated. Pump up the tire and you have a practical puncture-proof and-long-running tire. I want to know if any of your readers have tried this. Is sand liable to work between the two casings? Would there be enough friction to heat and harm the under casing?

Back Bay, Wis. W. B. DULING.

—There is a possibility that sand would work in and cause trouble. Some slight harm might also be done by heat. The experiences of our readers on these points would be interesting.

Lamps Out of Focus

Editor THE AUTOMOBILE:—I have a motor car equipped with the Gray & Davis electric lighting system. So far as the efficiency of this outfit is concerned, there is no fault to be found. The bulbs in the headlights are bright enough, but the light on the road is bad—simply a series of light and dark rings. However I may try to adjust the focus the result is the same, while the diameter of the circle of light on the road is only about 12 feet at a distance of 20 yards. Will you please tell me what is the matter, and how I may get rid of those rings?

Jamaica, West Indies. JAMES JOHNSTON, M.D.

—If the focusing apparatus is in proper working order and you are using the right size of bulbs, you should have no difficulty in eliminating the rings, as this trouble is due to lack of focus. The construction of the apparatus is shown in Fig. 2, where it will be seen that the position of the bulb is changed by a system of levers that is controlled by the nut at the top of the lamp. It is barely possible that a pin has dropped out or some other small derangement has occurred to prevent the proper focusing. It seems most likely, however, that the bulb is not the proper size.

Maker of First Automobile

Editor THE AUTOMOBILE:—1—Who made the first automobile? What year? Describe it.

2—How many factories in the United States to-day are making cars and trucks?

3—How many men are earning their living in these factories?

4—What particular improvements on cars gave them reliability?

5—What is the approximate number of cars and trucks in use to-day in the United States and their value.

Scranton, Pa. JOS. J. CURT, JR.

—1—This is a difficult question to answer, because self-propelled road vehicles appeared shortly after the invention of the steam engine, and as a natural consequence of it. The first one we have any record of is Cugnot's steam carriage, built in 1770. This is illustrated in Fig. 3. The boiler is carried in front and drive is through the front wheel. It was capable of carryng four people at a speed of 2.25 miles per hour on an ordinary road. As its boiler capacity was insufficient, it was not able to run more than 15 minutes before pausing to get up steam.

The kettle-shaped boiler is characteristic of the day; the fire and water tube boilers had still to be invented.

The single front wheel, which is of great strength and weight, is driven by two single-acting vertical cylinders 13 inches in diameter by 13-inches stroke. These two pistons are connected by a walking beam to which they are coupled by chains attached to levers mounted on the axle of the driving wheel. They alternately work the front wheels by pawls acting on two modified and reversible ratchet wheels. The distribution of the steam to the two cylinders is effected by a four-way cock, so arranged that in each position it opens one cylinder to the steam supply and the other to atmosphere. It is operated by a tappet motion from the piston rods. The rear part of the machine was connected by a vertical bolt to the front wheel, and by means of gearing from the driver's seat of the fore carriage can be turned through 50 degrees, thus enabling the driver to steer the carriage.

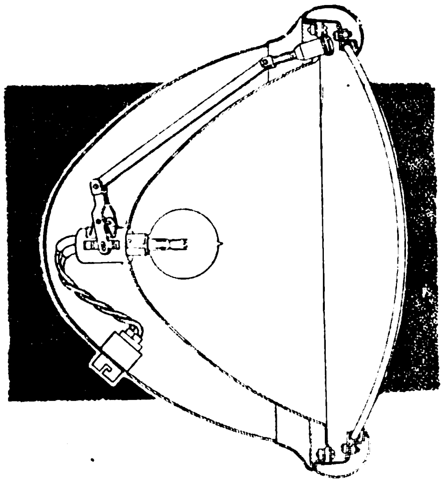

Fig. 2—Gray & Davis electric headlight, showing bulb focusing mechanism

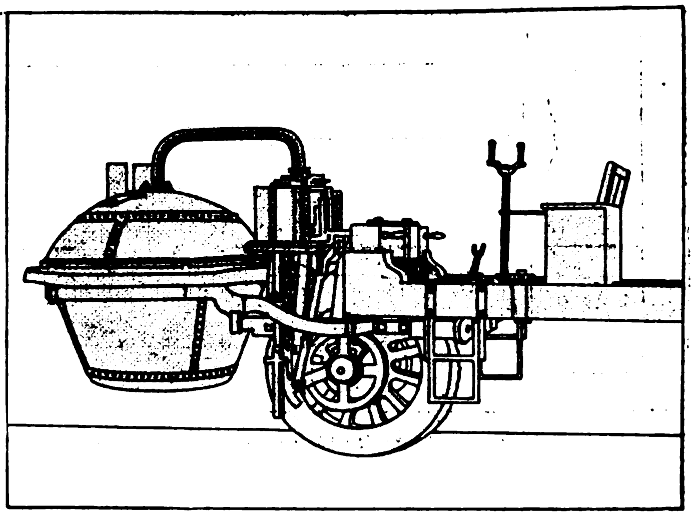

Fig. 3—Cugnot's steam carriage, built in 1770

2—The total number of manufacturers, according to the *Automobile Trade Directory*, is 436, distributed as follows: Gasoline pleasure cars, 171; electric pleasure cars, 24; steam pleasure cars, 2; cyclecars, 29; gasoline commercial vehicles, 188; electric commercial vehicles, 22.

3—This is unobtainable.

4—Reliability has been achieved mainly by the perfection of details, due to experience. Little by little, the proper materials, proportions and size of parts for best service have been determined. Reliability has not been obtained by changes in principle to any extent.

5—Slightly more than a million and a half vehicles were in use at the beginning of July. The total value is not known.

Motor Fires Irregularly

Editor THE AUTOMOBILE:—My motor does not fire regularly. Sometimes it misses on just one cylinder and then again two become affected. The missing skips around from one cylinder to another. The position of the gas and spark levers does not seem to make any difference, and the trouble is equally bad on both magneto and battery. The magneto is a Splitdorf. Every adjustment of the carbureter, which is a Schebler, has been tried, and other carbureters have been put on, but without success. The spark plugs have been changed.

The motor has been completely overhauled by a competent mechanic.

Earlhorn, Ia. GEO. PHILLIPS.

—There are many places where you might find trouble according to the symptoms you have described. Since the missing is not confined to one cylinder, however, the spark plugs must be in good condition. Probably, also, the valves do not need regrinding, nor is the trouble due to lack of compression from any other cause.

The missing is undoubtedly caused by faulty ignition or carburetion, and it seems more likely that the former is the cause.

First look for short circuits. Operate the motor in the dark, at a moderate rate of speed, and note whether any sparks jump from any part of the wiring to the motor or frame. Inspect the insulation of all the wires carefully for worn or broken spots, where a short circuit to the frame might be produced. Any such spots should be taped or the wires replaced. See that no exposed parts, such as terminals, are able to come into contact, even momentarily, with any metal parts that might ground the current.

Next examine the brushes on the magneto. Any that are worn on the ends should be smoothed off or replaced, so that a good electrical contact is obtained. The springs that force

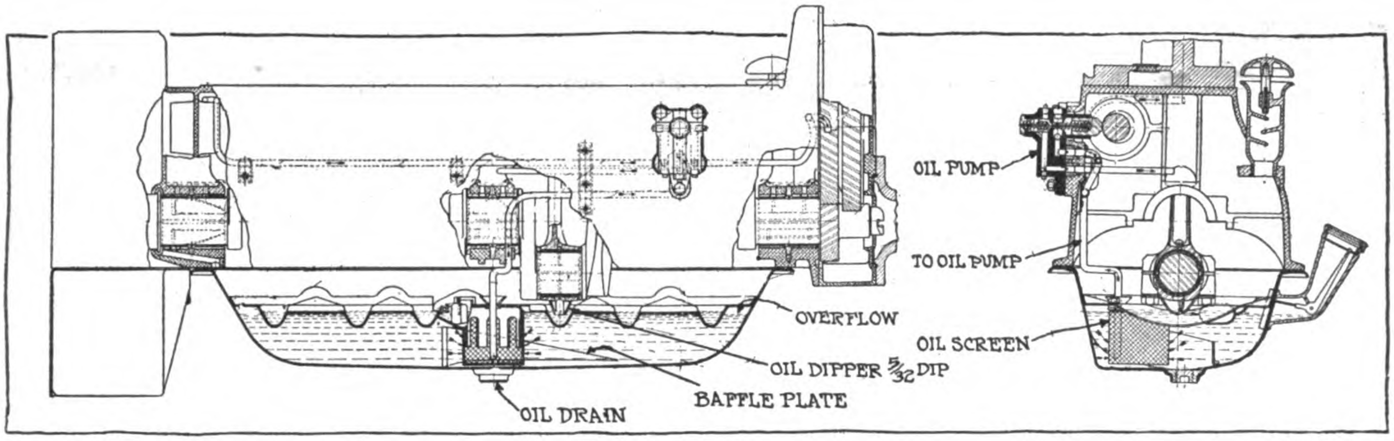

Fig. 4—Oiling system used on 3.75 by 5-inch Continental Six. A combination of splash and pressure feed is used

out, or feed, the brushes should have enough tension to make a good contact, and if any are too weak new ones should be substituted.

See that the breaker points are smooth enough to meet squarely and in adjustment—that is, the gap between them, when they are separated, should be between 1/32 and 1/64 inch. Also note whether the insulation in the breaker box is in good condition, and whether there is any possibility of a short circuit either due to this cause or dirt or oil. Wash the breaker mechanism well in gasoline before replacing. See that there is no dirt in the spark gap that might cause a short circuit.

Take the switch apart and examine the insulation and tighten up any loose parts.

Then, providing all electrical connections are tight, and the gaps of the spark plugs are adjusted to about 1/32 inch, the trouble must either be in the carburetion system or else is in the coil or magneto. In the latter case take your car to a Splitdorf service station.

Assuming that the carbureter adjustment is about correct, see that there are no air leaks in the intake manifold. This fact can easily be determined by running the motor and holding a cigarette at the various joints. If there is a leak the smoke will be sucked in. The trouble may be caused by a worn gasket or some of the flange bolts may be loose.

Look for dirt in the gasoline system and see that the float is not soaked with gasoline and that the needle valve and float valve or their seats are not worn.

Description of Continental Six Oiling

Editor THE AUTOMOBILE:—Will you please describe the oiling system used on the six-cylinder Continental motors?

St. Louis, Mo. E. H. K.

—Two oiling sytems are used; one is a splash system employing a gear pump, Fig. 4. This is found on the 3.75 by 5.25-inch motor, while a plunger pump is used on the 3.5 by 5-inch motor.

In the former, the pump, which is driven by spiral gears, forces the oil through three pipes which lead to the three main bearings of the crankshaft. The oil which is not used up here overflows into the splash pockets of the oil pan, where it is picked up by the connecting-rod dippers, thus lubricating all exposed bearing surfaces inside the motor.

On the larger motor a plunger pump operated from a single eccentric on the cam shaft is used, the oil being drawn through a single lead from the tank and forced through three separate leads to the main bearings.

Gasoline Consumption Is High

Editor THE AUTOMOBILE:—I have a two-cycle Elmore, model 36, and cannot get over 6 or 7 miles to the gallon of gasoline. Is there any attachment that could be connected to the carbureter that will increase the number of miles per gallon? It is a Schebler carbureter and the engine works all right in every other respect.

Greensburg, Pa. E. G. SHEETS.

—This consumption is not unusual for this particular make and model. You might improve it somewhat by adjusting the carbureter to give a very lean mixture, running with spark advanced as much as possible, and reducing the friction of all parts to the minimum. You might also attach a gasoline economizer.

Worn Cylinders Cause Smoking

Editor THE AUTOMOBILE:—I have a 2-ton truck which has only been driven about 7,000 miles and has had the best of care. It runs all right now with the exception that it smokes a great deal regardless of how little oil I carry in the crankcase. I am also very careful about the sight feed on the dash not feeding too quickly. I have been told to drill holes in the oil grooves near the bottom of the pistons to allow the excessive oil to pass down through the inside of the piston back to the crankcase. Do you think this will prevent further smoking?

New York City. E. A. C.

—The only explanation is that the cylinders are badly worn, either through abuse or accident. The best remedy is to rebore the cylinders and fit new rings and larger pistons, but relief can be obtained in the way you suggest, namely, by drilling holes in the oil grooves in the bottoms of the pistons.

Truck Should Ride Better Loaded

Editor THE AUTOMOBILE:—1—We are using a 3-ton Mack truck with a twenty-six-passenger body. We find that unless it is fairly well loaded, the car rides hard. We thought that by the use of shock absorbers we could make the car ride more easily. Do you think this is so?

2—Can you advise us where we can obtain absorbers suitable, at a moderate price?

Bath, N. Y. BUCHMASTER & MORRISON.

1—Shock absorbers should improve the riding qualities, but it is natural that the truck should ride harder when empty. The springs of this vehicle, the same as any other, whether it be a pleasure car or a buggy, are designed for the maximum load, and therefore the truck rides best when this load is applied.

2—We suggest that you write some of the following manufacturers of shock absorbers:

Connecticut Shock Absorber Co., Meriden, Conn.
Cox Brass Mfg. Co., Albany, N. Y.
Ernst Flentje, Cambridge, Mass.
Gabriel Horn Mfg. Co., 1407 40th street, Cleveland, O.
Hartford Suspension Co., 172 Bay street, Jersey City, N. J.
Martin Shock Absorber Corp., 1301 E. Slauson avenue, Los Angeles, Cal.

Clarence N. Peacock, 1790 Broadway, New York City.
Peteler Shock Absorber Corp., 1997 Broadway, N. Y. City.
J. H. Sager, 265 South avenue, Rochester, N. Y.
Westinghouse Air Spring Co., Smedley Bldg., New Haven, Conn.

Carbureter Causes Missing

Editor THE AUTOMOBILE:—I have a 1913 runabout, and it has a miss somewhere. At low speed it runs very well, but every 10 or 15 revolutions it seems to have an extra exhaust, and when attempting to speed up the motor one or more cylinders will miss until the speed gets high, and then they will all hit. It does the same thing on the road. I have rewired from the magneto to spark plugs and changed spark plugs several times. Do you think it is the fault of the carbureter? If so, what would you recommend?

Somerset, Ky. ROY J. MCDANIEL.

—You seem to have carbureter trouble. Adjust your carbureter carefully, and if you do not understand how to do this properly take your car to a competent repairman. If the motor still misses it would be well to install another carbureter.

It is possible, also, that the breaker points on the magneto are out of adjustment, or that the magneto is at fault elsewhere. See the answer to George Phillips' letter in this issue, page 489.

Spark Plug Pump All Right

Editor THE AUTOMOBILE:—I have been informed that the use of an impulse pump for inflating tires will in time cause a noticeable knock or pound in the motor. If so, would you kindly explain?

Sayre, Pa. J. W. G.

—There is no reason why a spark plug pump should cause a knock in the motor. It is entirely separate from the motor, as far as its moving parts are concerned. Only the lower end comes in contact with the cylinder, and this has no more effect on the motor than a spark plug. The movement of the piston in the pump is produced by the compression pressure. There is mechanical connection between the pump and the motor.

How Car Drives Through Springs

Editor THE AUTOMOBILE:—Please explain the meaning of the phrase, "Car drives through springs."

Milwaukee, Wis. W. F. BREHM.

—This expression is almost self-explanatory. It means that the driving force exerted on the car body by the wheels is transmitted through the springs instead of through a torque-tube or radius-rod construction.

The three methods of driving are illustrated in Fig. 5. At the left is shown how the drive is taken by the springs. The forward thrust of the wheels, which is exerted first on the axle, is transmitted to the body through the front ends of the springs. No force can be applied at the rear ends of these springs because of the shackle construction. The forces are indicated by the direction of the arrows.

The use of radius rods to transmit the driving effort is illustrated in the center. It will be noted, in this case, that the springs merely carry the load and that all the strain of propelling the car falls on the radius rods. These are pivoted to the frame by means of ball and socket joints and are fastened to the axles by collars which allow full radial movement.

In the torque tube construction, at the right, the driving force is transmitted to the car through the pins P. In principle this is the same as the radius rod just described, but this member has another function also. Since the tube is fastened solidly to the axle, any tendency of the axle to rotate when the driving torque of the wheels is applied, is resisted by this member.

Breaker Points Too Near

Editor THE AUTOMOBILE:—I have a 1913 touring car which is not working satisfactorily of late and would like to know the reason for this.

I had the car overhauled recently on account of valve trouble with two cylinders. Had new piston rings installed, and also other parts which were necessary. The car now has good compression on all cylinders, but does not pick up and take the hills the way she should. I have tried this with the spark lever in different positions, but with no improvement. I also had the carbureter, which is a Rayfield, overhauled and adjusted. The car throttles down satisfactorily on high speed, almost to a walk, but on a long, steep hill she will slowly decrease in speed until engine is just turning over, necessitating changing to a lower speed.

Brooklyn, N. Y. PETER KAMINSKI.

—Possibly the motor is merely stiff and that after the new parts are worn in the car will accelerate properly. Also, it may be that in reassembling the motor the timing of the valves or magneto was incorrectly done. More likely the former, because the motor would either overheat or knock if the setting of the magneto was much out of the way. There is some chance too that the points of the breaker are too near. Make certain that the brakes are not dragging.

Relative Power of I and T-Head Motors

Editor THE AUTOMOBILE:—Will you kindly tell me what percentage of horsepower an overhead valve motor will develop over a T-head motor of same bore and stroke?

Sturgeon Bay, Wis. C. C. DONA.

—The exact increase, if any, with the overhead-valve construction depends on so many things that it is impossible to give definite figures. The exact design of the combustion chamber; the size, lift and timing of the valves; the shape and size of the intake and exhaust manifold, and the position of the carbureter all have their effect.

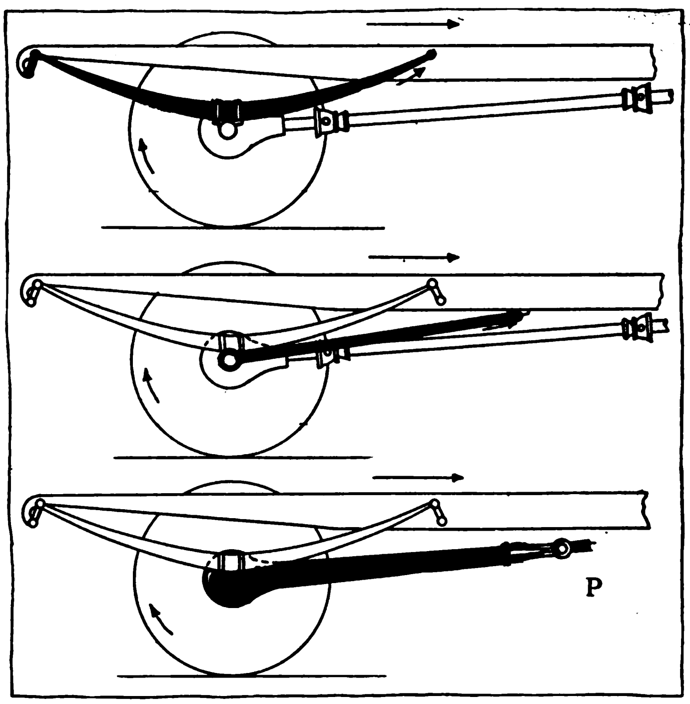

Fig. 5—Diagram showing the three methods of transmitting the driving force from the axle to the frame. The top one shows how the drive is taken through the springs, the middle one by radius rods and the lower one by the torque tube. The blackened member in each case is the one carrying the stress

The Engineering Digest

For What Speed Should a Motor Be Designed to Give Maximum Power For Its Weight?

A BRITISH ARGUMENT FOR AMERICAN MOTORS

CONSIDERING that it is usually taken for granted that a motor with small cylinders and capable of being operated at very high speed—giving its maximum power somewhere close to 3,000 revolutions per minute, for example—can be much lighter per horsepower than a motor designed to develop maximum power at 1,500 revolutions, an argument to the contrary of this assumption offered by *Engineering*, of London, in its issue of August 21 will be found of interest. The reasoning is expressly intended to account for the popular liking shown for American automobiles in Europe and to suggest that European builders would do well in going back to relatively slow-speed motors in lightweight car constructions. It runs substantially as follows:

Where the Weight Lies

In any comparison equal standards of durability must of course be assumed. It is first to be remembered that the weight of the cylinder barrels is not the most important item in the upright automobile motor. Valve seatings and boxings usually weigh more. Crankchamber, crankshaft and bearings make up a very large part of the total. The sizes of these parts depend upon the pressures and can therefore be made lightest where the pressures are smallest. The greatest weight-saving from reducing cylinder size is obtained in the aeroplane motors with cylinders radiating in one plane, because in these the number of cylinders is large while the weight of shaft and casing are relatively small.

Up to a certain point lightness is no doubt most readily secured by small cylinders and high speed, as the explosion pressures are reduced with the size of cylinders, but, even if these pressures alone are considered, the weight reduction is not in proportion to the increase in number of revolutions, because valves and valve gears must remain the same for a given power, whatever the speed, and the rubbing speed of journals is increased, so that their areas cannot be reduced in proportion with the load reduction. Moreover, the length of these bearings largely determines the length of crankshaft and casing.

At really high speeds—that is, beyond the limit within which a gain in lightness is after all secured—the question is complicated by the growth of the pressures due to inertia of the moving parts. These go up at the square of the speed and come to exceed the explosion pressures. They cannot be cushioned by a constant application of the power, as in high-speed steam engines. The crankshaft and other parts must be enlarged to take these stresses, and the bearings must be increased in area. As the rubbing speed is greater, the bearing pressures per square inch must be lower, and the area of bearings must therefore be increased at a ratio above the square of the speed; and there will be a point beyond which the increase in weight will be greater than the increase in horsepower.

The compression used also affects the results. In a high-speed motor high compression must be used in order to get the charge burned in the available time. And, while the mean pressure during the working stroke is not materially raised by a very high compression, the maximum explosion pressure is raised considerably and must be provided for.

Calculated Forces in Three Cases

The relative effects of the explosion and the inertia forces in three motors of the same power, but of different speeds and with cylinders of different sizes, are scheduled in Figs. 1, 2 and 3, in all of which A represents the shaft of a low-speed motor, B that of a medium-speed and C that of a high-speed motor. Different sets of stresses are represented by the inscribed figures, which have been calculated from the supposed data of the three motors. Motor B may be supposed to run at 1,500 revolutions, developing 40 horsepowers, and to have cylinders with 4-inch bore and 5-inch stroke. A and C are to produce the same power—A at 750 and C at 3,000 revolutions—and for convenience it may be assumed that they all have the same stroke. In this case A will have a bore of 5.66 inches and C one of 2.83 inches. The reciprocating parts of A, B and C may be taken to weigh 7, 3½ and 1¾ pounds, respectively, and the rotating parts are estimated at 6 pounds in all three cases, including the connecting-rod knuckle with bushings, 50 per cent., and the crankpin and portions of the cheeks the other 50 per cent. The explosion pressure can be assumed to be 300 pounds per square inch in every case. These supposed data come near enough to realities for purposes of comparison.

Fig. 1 gives the forces acting on the crankpins to produce bending stresses on the shaft and pressures on the main bearings. In the low-speed motor A the maximum force on the pin is 6,836 pounds, due to the explosion pressure. In B this is reduced to a maximum of 2,047 pounds, partly owing to the reduction of the piston area and partly to the increased inertia of the parts which act against the explosion pressure. But in C the maximum acting on the shaft is 5,242 pounds and is due to the inertia forces at the end of the exhaust stroke.

The size of shaft necessary for strength depends on these forces and the distance between main bearings, and the latter depends largely upon the required length of the connecting-rod bushings. The pressures upon these bushings—by which their length is dictated—are given in Fig. 2, where it is indicated that the crankpin pressure maximum is 6,957 pounds in A and is due to the explosion pressure, is 2,531 pounds in B, but rises to 3,306 pounds in the high-speed motor C by reason of the inertia forces. In considering the effects of the pressures it must be remembered that the areas should depend not only on maximum values but also on the mean or average values by which wear is largely determined. The inertia pressures are to be sustained at three out of four stroke reversals, so far as those due to the reciprocating parts are concerned, and all the time in the case of the centrifugal forces, while the explosion pressures occur only at the working strokes. The mean values are thus much higher in the C type.

It must also be remembered that in the C type the very fact of adding to the size of the knuckle and crankpin bearings, in order to meet the stresses, adds to the weight of the revolving parts and therefore to the centrifugal forces, and that a larger area for the unit of load should be allowed in this type on account of the higher rubbing speed.

All considered, it is seen that the knuckle bearings will have to be very much longer in C than in B and probably quite as long as in A. To keep the stresses uniform, the shafts will have to be much in the same proportion. Owing to the extra weight of crankpins and knuckles, the actual pressures on the main bearings of C will be greater than shown by the figures. The middle bearing has to carry very heavy pressures at the bottom of the stroke of the two middle cylinders, the two end-bearings having corresponding upward pressures, and these conditions are reversed, of course, each half revolution. This explains the great length always given the middle shaft bearing in a motor of the C type with three bearings.

From all of these considerations it is at least evident that there is a very definite speed which will give the lightest motor. To ascertain what this speed is the conditions should be carefully studied and the probable weight of all parts determined with fair accuracy. Curves of the pressures and stresses could then be laid out which would give the desired information, but the best speed will, of course, always depend largely upon the general design of the motor and upon the standard of durability desired. It is noticed that successful builders of aeroplane motors, though the standard of durability for these is not high, keep revolutions below 1,500.

Throttled Running Emphasizes the Moral

In the argument, the effect of the flywheel has so far been ignored and the motors have been considered as running at full power only. It seems probable that in the case of single-cylinder motors for motor cycles high speed is necessary for lightness by reason of the need of keeping the flywheel size within bounds. With regard to motors for automobiles two fresh factors come into play. The fact that a wide range of motor speeds is required—in order to take hills on high gear—favors the high-speed motor, as a large flywheel is wanted to make a very large motor run slowly. On the other hand, the fact that the motor is mostly run throttled favors the slow-speed type, from the fact that explosion pressures are reduced while the inertia forces remain the same. In a car with a fair reserve power the motor usually works at perhaps a quarter of its possible power, and while the explosion pressure does not fall quite in proportion to the mean pressure, it is probably below 150 pounds per square inch most of the time in a 40-horsepower motor. Hence Fig. 3 shows the forces on the crankpin, and therefore those on the main bearings, at this pressure. In this case the maximum for A is 3,136 pounds, for B 1,653 pounds and for C 5,242 pounds. Further, the mean pressures for C are enormous, while in A they are very low. It is therefore probable that the A type, with a speed of 750 revolutions, could be built very nearly as light as the B type of 1,500 revolutions and a great deal lighter than the C type of 3,000 revolutions—durability even.

Conclusions

It is evident that motor speed should be as low as consistent with lightness, as all the practical advantages lie with the low-speed motor, particularly in the matters of maintenance, noise and price. Probably 1,500 revolutions should give the maximum power, which would mean that the motor in ordinary automobile practice would be run at about 1,000 revolutions, in order to have a reserve. This matter is of great importance, in view of the very great extension of the American motor car trade. Price is only one factor of their sales, the really important point being that their cars are light for their power and quiet; both these advantages coming largely from the use of moderate-speed motors.

Dimensions of Valve Control Organs in Automobile Motors—Calculations and Formulas

A SERIES of formulas for determining the dimensions of valve control organs in automobile motors is presented with brief reasoning by the German engineer, A. G. Von Loewe. Their value lies largely in the suitable choice of the factors which are considered as known and by which those sought are determined, this choice rendering it possible to apply the formulas directly to different designs of motors, independently, for example, of variations in the valve timing. The subject comes in several divisions; namely, (A) dimensions of intake channel, (B) dimensions of valve springs, (C) forms and sizes of cams, (D) adjustment of cams (valve-timing), (E) tappet rods and rollers and (F) camshafts.

In the following the notations used are boxed to facilitate the reading.

Notations

c = mean piston speed, in meters per second, m/sec.
v = mean gas velocity in suction channel, in m/sec.
d = cylinder bore, in centimeters, cm.
d_1 = diameter of suction channel, in cm.
f = sectional area of suction channel, in square centimeters, cm^2.
F = piston area, in cm^2.
d_2 = mushroom valve diameter, in cm.
d_3 = valve stem diameter, in cm.
l = valve stroke, in cm.

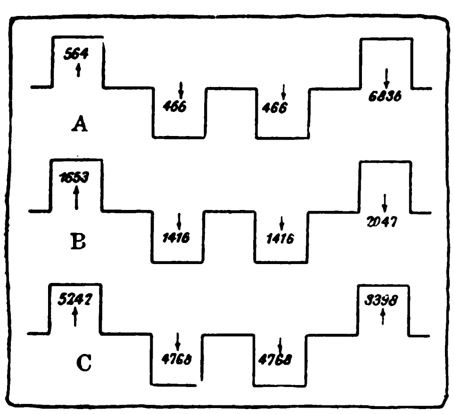

Fig. 1—Maximum forces producing bending stresses of crankshaft and pressures in shaft bearings

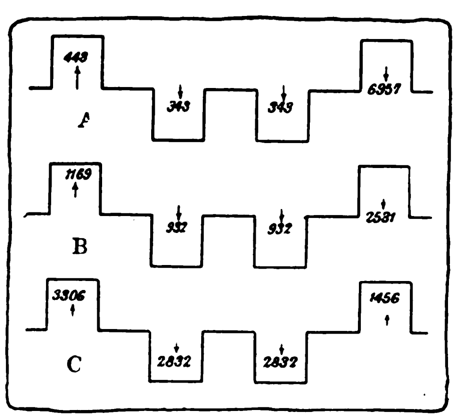

Fig. 2—Maximum stresses upon crankpins on bushings of connecting-rod knuckles

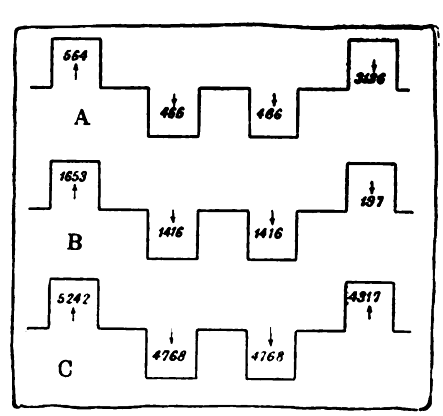

Fig. 3—Forces acting on crankshaft (as in Fig. 1) when motor is throttled to ¼ power, though running at full speed.

As f and F, and therefore also the squares of d_1 and d, must be inversely proportionate to v and c, one has

$$\frac{d_1^2}{d^2} = \frac{c}{v} \text{ or } d_1 = d\sqrt{\frac{c}{v}} \text{ and also } f = F\frac{c}{v}$$

Taking for v a gas velocity of 50 meters per second [which should be considered a minimum—Ed.] the following values are obtained:

Sectional area of suction channel $= f = .02\ Fc$ and

Diameter of suction channel $= d_1 = .14\ d\sqrt{c}$ (1)

The stereometrical relations or the standard formulas on the subject give further:

Diameter of mushroom valve $= d_2 = 1.2\ d_1$ (2)

Diameter of valve stem $= d_3 = .1\ d_2 + .4$ cm. (3)

Valve stroke $= l = \frac{f}{\pi d_1} = .32\frac{f}{d^2}$ (4)

Valve Springs

The valve springs must be capable of resisting the depression occurring in the cylinder when the motor is operating with the throttle closed. This is a minimum requirement.

Notations

p_0 = pressure at beginning of suction stroke.
v_0 = volume of gas at beginning of suction stroke.
p = pressure at end of suction stroke.
v = volume at end of suction stroke.
p_1 = depression; P_1 = depression acting upon intake valve, in kilograms, kg.
e = volumetric compression; P = spring tension with valve closed, in kg.

One has $\frac{p}{p_0} = \frac{v_0}{v}$, as pressures and volumes are inversely proportionate; therefore $p = \frac{p_0\ v_0}{v}$, and as $p_0 = 1$ kg. per square centimeter and $\frac{v}{v_0} = e$, being the volumetric compression, then $p = \frac{1}{e}$. The depression $p_1 = 1 - p$ and therefore

$$p_1 = \left(1 - \frac{1}{e}\right) = \frac{e-1}{e}, \text{ in kg/cm}^2.$$

The force of the suction to be resisted is further specifically dependent on d_2, the diameter of the valve, and thus

$$P_1 = \frac{\pi d_2^2}{4}\cdot\frac{e-1}{e}, \text{ in kg.}$$

In practice this minimum should be exceeded, say doubled, in order to accelerate the closing of the valve with sufficient vim. Figuring with $e = 4.25$ [which stands for a high compression and a small combustion chamber if the opening of the intake valve is delayed 45 degrees, for example, beyond low dead center—Ed.], the spring tension may therefore be calculated as

$$P = 2P_1 = \frac{\pi d_2^2}{2}\cdot\frac{3.25}{4.25} = 1.2\ d_2^2, \text{ in kg.} \quad (5)$$

Other Notations

P_2 = tension of entirely compressed spring, in kg.
P_3 = tension of spring when valve is entirely open, in kg.
L = length of spring with valve closed, in cm.
L_1 = length of entirely compressed spring, in cm.
L_2 = length of spring with valve entirely open, in cm.
L_3 = length of released spring, in cm.
f = deflection of spring by tension P, in cm.
f_2 = deflection of spring by tension P_2, in cm.
f_3 = deflection of spring by tension P_3, in cm.
d = diameter of the spring wire, in cm.
r = mean radius of spring coil, in cm.
i = number of fully effective coils of spring.
d_2 = diameter of valve; l = valve stroke.

To introduce a factor of safety against snapping of a spring, it may be assumed that the spring with the valve closed is deflected only one-half of its total stroke, this meaning that $f = .5\ f_2$ and $P_2 = 2P$.

The radius r is determined by constructive relations and may be taken as a known factor. We can thus apply to P_2 the standard formula for maximum pressure of a coil spring with round wire, so that

$$P_2 = \frac{\pi d^3}{16r}\cdot \text{kd}$$

in which kd is the admissible maximum torsional load, and if kg. is taken at 4,500 kg. per square centimeter, this being the accepted figure for hardened machinery steel of good grade, there is obtained for d, the diameter of the wire, the value

$$d = .13\sqrt[3]{P_2 r}, \text{ in cm.} \quad (6)$$

For f_2 the standard formula gives the value

$$f_2 = \frac{4\pi i r^2}{d}\cdot\frac{\text{kd}}{G}$$

in which G is the modulus of torsional elasticity. If the value of G is taken at 750,000 kg. per square centimeter, being the accepted figure for good hardened machinery steel as before, the formula for f_2 becomes

$$f_2 = .075\frac{ir^2}{d} \quad (7)$$

The derived values of interest are readily seen to be as follows:

$$f = .5\ f_2$$
$$L_1 = (i + 1)d$$
$$L = L_1 + f$$
$$L_2 = L_1 + f_3$$

With the valve fully opened:

$$P_3 = P\left(\frac{l}{f} + 1\right)$$
$$L_2 = L_3 - (f + l)$$
$$f_3 = f + l$$

(To be continued)

Electro-Magnets for Scrap Removal

Detroit, Mich., Sept. 2—A huge electric magnet that carries 3,000 pounds of steel as easily as the five-cent variety will pick up a needle, is one of the modern means of transportation to be seen at the plant of Dodge Bros. in Detroit.

Electro-magnet dumping scrap in Detroit

From the forge and stamping rooms a constant procession of scrap iron and steel emerges, and in order to remove this quickly, the magnet plan was adopted. The crane is operated by a man seated in the cage at the left, and travels on an overhead track 400 feet long, leading to a railway track.

Fifteen Makers Get War Premium

On March 31, 1913, Germany Had 825 Commercial Vehicles Subsidized for War Purposes

IN 1913 the German government had a law passed the Reichstag whereby motor vehicles could be purchased and premiums allowed for them if they came up to the specifications and requirements of the German war department. In other words, the army was allowed to supply itself with vehicles owned or operated by the industrial establishments in Germany and the owners were given a subvention and allowed a premium.

On March 31, 1913, it was 5 years since the law had been passed and on that date, according to the official records, there were 825 motor vehicles at the service of the army; that is, vehicles for which subventions had been paid and premiums allowed, while there were 400 more vehicles in the empire which came up to the military requirements and could be used. Thus only 1,225 automobiles suitable for military purposes, according to the army regulations, were owned in Germany in March, 1913.

825 Vehicles Accepted by the Army

The 825 vehicles accepted by the army were made by fifteen German manufacturers and 165 of them, or 20 per cent., were Daimlers or Mercedes-Daimlers. H. Bussing, probably the oldest exclusive commercial vehicle builder of Germany, was second on the list with a total of 137 or 16.6 per cent. The N. A. G. company of Berlin followed with 108 or 13 per cent., and Benz came fourth with 103 or 12.5 per cent. In the case of Benz it must be mentioned that it ought to be the Gaggenau company, which was purchased a few years ago by the Benz works. The exact number of vehicles secured by the army department each of the first 5 years on record is given in the accompanying table, while the second chart shows in which industrial enterprises or business the 825 vehicles had been used.

The subvention allowed by the government amounts to 3,000 marks, or $750, for an army truck with one or several trailers, and 1,800 marks, or $450, for an ordinary truck. This subvention is what might also be called the purchase price, but during the succeeding 4 years the owner receives as a premium 1,200 marks, or $300, annually in the case of an army train—truck with a trailer or several—and $200 annually for an ordinary truck.

Many Conditions to Fill

In order to be acceptable for military use the vehicle must fulfil many conditions, among which the following are the most important: The army train trucks, with two men aboard and their regular equipment and supplies of water, gasoline, oil, spare parts, must be able to carry a load of 4,000 kilos, or 8,800 pounds, and pull a trailer carrying a man and a load of not less than 2,000 kilos, or 4,400 pounds. Thus fully equipped, the army train must be able to climb grades of 1 in 7 and travel at an average speed of 16 kilometers, or 10 miles an hour. Trailers fully equipped must not weigh more than 2,500 kilos, or 5,500 pounds, and must carry a load of at least 2,000 kilos, or 4,400 pounds. Fully loaded, the weight of a trailer must not be over 7,500 kilos, or 16,500 pounds. Army vehicles must be fitted with rubber tires. As for those vehicles having no trailers, they must not weigh over 9,000 kilos—19,800 pounds—when loaded, and under no circumstances must the weight carried upon the rear axle be more than 6,000 kilos, or 13,200 pounds. The weight carried upon 1 centimeter or .393 inch width of the rim may not be over 150 kilos, or 330 pounds.

It has been proven by the army experts that 50 per cent. of the vehicles which have been used either by the war department or by their owners during the period of 5 years were found still in very good condition after those 5 years and that after 6 years 30 per cent. were still serviceable for army purposes.

Subsidized by German Government During 5 Years Ending March 31, 1913

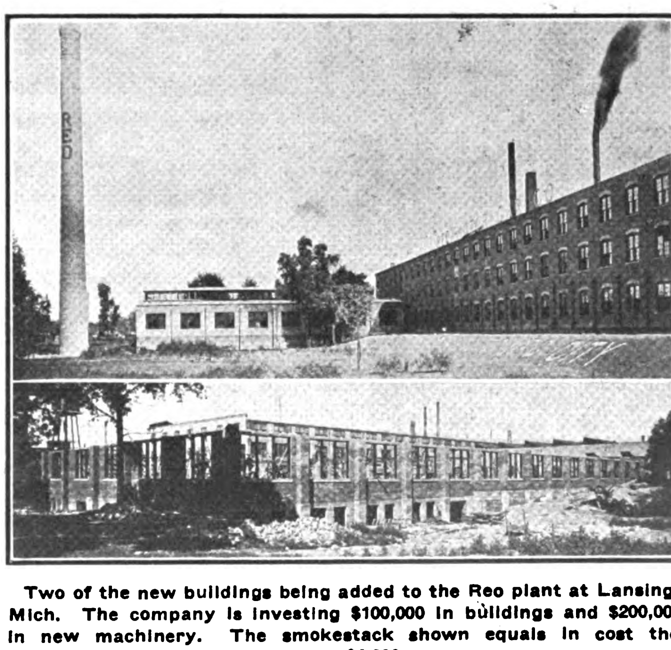
Reo Adds $330,000 Equipment

LANSING, MICH., Sept. 7.—The Reo Motor Car Co., which last week declared a dividend of 15 per cent. in connection with a 10 per cent. dividend declared by the Reo Motor Truck Co., is adding $100,000 worth of buildings and $200,000 worth of new machinery. New boilers and coal and ash handling machinery will cost $30,000 more. One of the new buildings will be a three-story construction which will house the trim shop, top department, gear paint shop, and various assembly departments, and will add 4.5 acres of floorspace to the company's factories. Another smaller building is to be devoted exclusively to the methods of heat treatment devised and adopted by the Reo engineers.

Another addition in the shape of a building 95 by 600 feet is being made to the general machine shop which is expected to increase the efficiency of that part of the plant at least 50 per cent.

The 1914 production was double that of previous years and even the 25 acres of floorspace which the company now has at its disposal will probably soon have to be increased.



Two of the new buildings being added to the Reo plant at Lansing, Mich. The company is investing $100,000 in buildings and $200,000 in new machinery. The smokestack shown equals in cost the selling price of four Reo cars, or $4,800

New Books for the Engineer

Works Include Dictionary of Mechanical Movements and Harper's Gasoline Engine Book

ONE of the most interesting books, to those who like mechanics or want information on mechanical movements and devices, is the work by Gardner D. Hiscox, M.E., entitled Mechanical Movements, Powers and Devices. Harper's Gasoline Engine Book on the other hand is for the man who is anxious to learn the principles of motor car construction and operation. It is simply written in non-technical language. There are many other books of iterest.

MECHANICAL MOVEMENTS, POWERS AND DEVICES. Fourteenth edition. By Gardner D. Hiscox, M.E., the Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 410 pages with 1,800 engravings, $2.50.

This edition is enlarged and improved in form. More than 160 up-to-date mechanical movements and devices have been added, including many straight line movements, thus making it a useful book of reference for those engaged in mechanical studies and pursuits, notably inventors and designers of machinery, in fact for all those who are interested in mechanics.

An enumeration of the subjects covered is impossible for reasons of space but it is sufficient to note that every conceivable mechanical device from valve movements to electric time clock transmission, is illustrated.

HARTNESS FLAT TURRET LATHE MANUAL, 1914. Published by Jones & Lamson Machine Co., Springfield, Vt.; 180 pages; cloth; liberally illustrated.

While this is published by a manufacturer of machine tools, it is in no sense a catalogue. It is intended as an aid to flat turret lathe operators in acquiring a true understanding of the machine and should be of value to anyone interested in machine tool work. Directions on speeds and feeds to use in doing different kinds of work are given and the operation of several types of turret lathes described.

HARPER'S GASOLINE ENGINE BOOK. By A. Hyatt Verrill, Harper & Bros., New York City, 293 pages with many engravings, cloth, $1 net.

The purpose of this book is to serve as a simple, practical, and complete guide for all those who own, use, or operate gas and gasoline motors. In its preparation every effort has been made to do away with technical terms and names and to adapt the book to the requirements of those who possess little or no knowledge of engineering or mechanics.

As far as possible all the principal and distinct types have been included and described as well as the more important or useful accessories, appliances, and fittings used in connection with motors.

In this book the marine, stationary, vehicle, and aeroplane motors have each been treated and described in separate chapters in addition to the clear and simple description of the principles, operation, and construction of motors in general.

The reader interested in some particular kind of motor can at once turn to the chapter dealing with this form without being obliged to read through the text relating to motors of other types.

Aside from the explanatory descriptions of the principles, operation, and construction of motors a great deal of space has been devoted to motor troubles and repairs. By its alphabetical arrangement this part of the book has been greatly simplified, and by referring to it almost any ordinary trouble may be located and remedied by an amateur.

The illustrations are nearly all original, the object being to furnish diagrammatic cuts which will clearly and simply accentuate the more important points described in the text.

PHYSICAL AND CHEMICAL PROPERTIES OF THE PETROLEUMS OF CALIFORNIA. By Irving C. Allen, Walter A. Jacobs, A. S. Crossfield, and R. R. Matthews. Published by the Bureau of Mines, Department of the Interior, 36 pages.

The pamphlet begins with an account of where the petroleum samples for analysis were obtained and a detailed description of how the samples were taken. Then the methods used in determining the physical properties are given, the specific gravity, flash point, burning point, viscosity, calorific value determinations being described in order. Then follows an account of the method used in fractionation, or separating each oil into its crude commercial components. At the end of the pamphlet several pages of tables giving the composition of various oil throughout the state are appended.

MASSACHUSETTS HIGHWAY COMMISSION. Twenty-first annual report for the fiscal year ending November 30, 1913. Wright & Potter Printing Co., 32 Derne street, Boston, Mass. Cloth, 220 pages.

This is a complete financial report of the money expended on the road for the year. The condition of the roads in various parts of the state before repairs were made is described and then the work done on them, and the manner in which it was accomplished, is told. There are chapters on maintenance and resurfacing, traffic and maintenance and suggestions are given for road legislation.

HARDENING, TEMPERING, ANNEALING AND FORGING OF STEEL. By Joseph V. Woodworth, the Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 288 pages, 200 illustrations, $2.50.

A new work treating in a clear, concise manner all modern processes for the heating, annealing, forging, welding, hardening and tempering of steel, making it a book of great practical value to metal working mechanics in general, with special directions for the successful hardening and tempering of all steel tools used in the arts, including milling cutters, taps, thread dies, reamers, both solid and shell, hollow mills, punches and dies, and all kinds of sheet metal working tools, shear blades, saws, fine cutlery and metal cutting tools of all descriptions, as well as for all implements of steel both large and small. In this work the simplest and most satisfactory hardening and tempering processes are given.

The uses to which the leading brands of steel may be adapted are concisely presented, and their treatment for working under different conditions explained, also the special methods for the hardening and tempering of special brands.

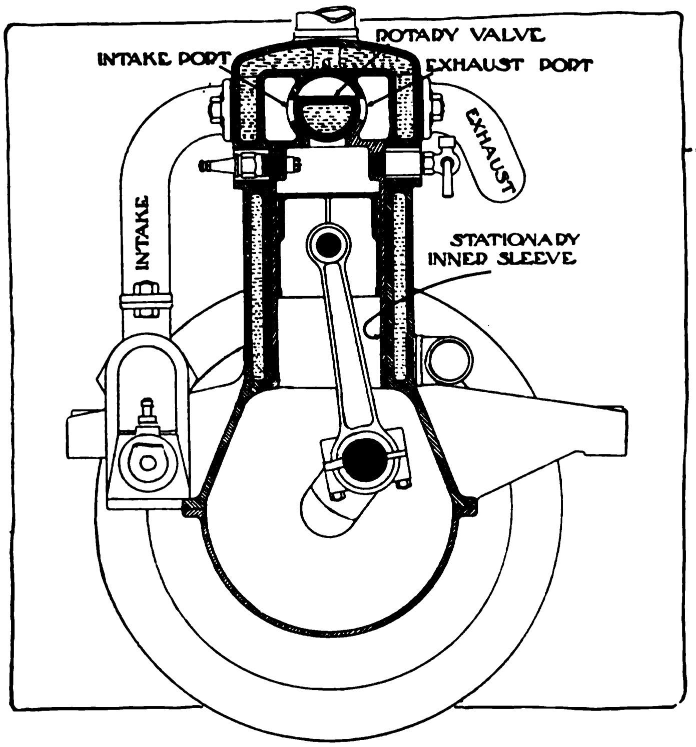
A chapter devoted to the different processes for case-hardening is also included, and special reference made to the adoption of machinery steel and tools of various kinds.

THE MOTORIST'S WORKSHOP. The Temple Press, London, E. C. 140 pages; cardboard; illustrated; 25 cents.

This is a handbook for amateur mechanics describing all essential operation in connection with metal working from the point of the motorist. The choice of a workshop is given consideration, and then materials and tools are discussed. Following this, are chapters on laying out work and drilling. Soldering, brazing and hardening are taken up and the operations described in detail. The remainder of the book, about half, describes the overhauling of the car.

WHO'S WHO IN THE AUTOMOBILE, 1914. J. R. Burton & Co., 1 Madison avenue, New York City. Paper, $2.

This book is an official directory of the state of New York containing the lists of permits issued, numerically arranged with the names and addresses of the owners and the names of the makes of the cars.



Transverse cross section through the Van Keuren rotary valve motor

New Rotary Valve Engine Is Simple Type

A NEW development of the rotary valve engine has been brought out by Henry P. Van Keuren, engineer in the Bureau of Highways, Philadelphia, Pa. There is a single rotary valve mounted directly over the top of the combustion space of the engine. This valve serves a dual purpose of intake and exhaust for all cylinders. It operates in conjunction with a common port in the center of the cylinder head. As shown in the illustrations, the valve is made of one piece, having a hollow center and extends the length of the engine. One of the odd features of this engine is the manner in which the rotary valve is kept sealed.

Extending downward into the cylinder casting, there is a sleeve which acts as the bearing surface for the piston and which has a cover acting as the bearing surface for the rotary valve. This sleeve is free to move in a vertical direction within the cylinder and although it remains practically stationary as far as the action of the engine is concerned, it acts as the means of sealing the valve port from the cylinder. The method in which this is accomplished is simply by the pressure of the gases within the combustion space. This pressure exerts itself equally on all parts of the combustion space and hence forces the sleeve tightly against the rotary valve.

No Valve Grinding

Of course, during the exhaust and intake strokes the pressure exerted by the inner sleeve against the valve is diminished and thus a virtual clearance is given between the valve and its housing. This permits the lubricating material to find its way along the surface of the sleeve oiling the working surface. The designer claims that during the life of the motor, the valve never requires grinding, as its wear is compensated for by the pressure of the sleeve against the valve.

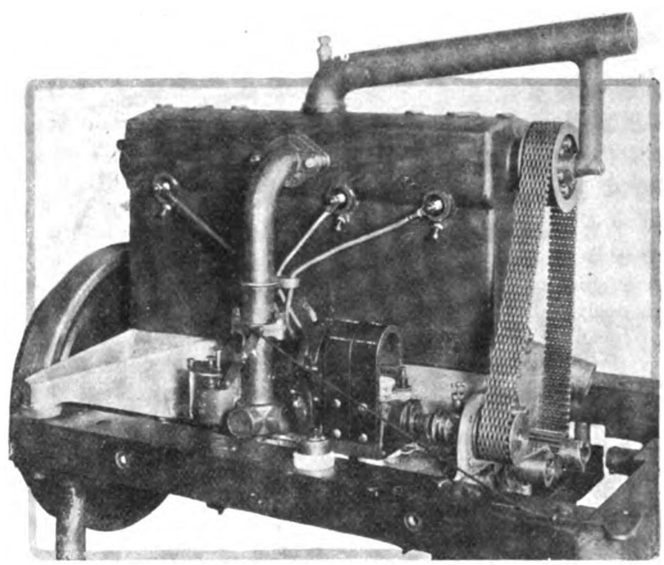
The valve is driven by a silent chain off the front end of the crankshaft. The same chain also drives the magneto. An idler pulley is inserted in the drive to maintain the correct adjustment on the chain. There is no sliding action in the entire valve mechanism of the motor, and its simplicity renders it of exceptional lightness. The rotary valve is driven at one-half the speed of the crankshaft and with the absence of reciprocating parts and spring returns in the valve action, a high rotary speed can be maintained with absolute precision in the valve action.

Oil Is Fed with Gasoline

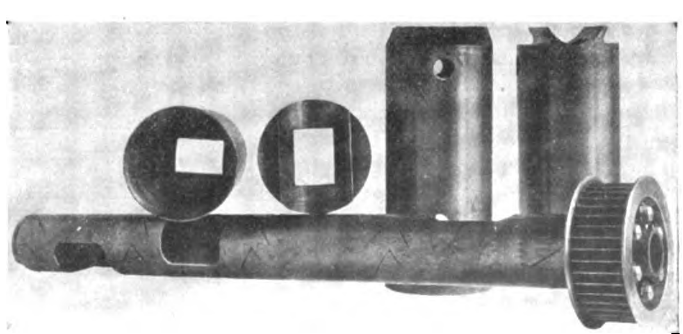
The size of the experimental motor is 4 by 4.75. It is lubricated by a splash system in the crankcase and the sleeve and other working parts are supplied with oil which is fed through the carbureter along with the gasoline.

In this motor the maximum port opening, or, in other words, the area of the common port is 17.6 per cent. of the piston area. While the inner sleeve is free, or rather a free sliding fit within the cylinder casting, there is no reciprocating motion of the sleeve. It remains constantly in contact with the valve itself. The makers of the engine at first supposed that the sleeve would drop from its uppermost position when the force of explosion in the cylinder had spent itself and the pressure of the gases dropped to atmospheric. Provision was made for this supposed motion of the sleeve in the form of an adjustable suspension by a set screw making contact with a shoulder or plug to which the priming cocks attached. This arrangement proved to be unnecessary.

The advantages claimed for the motor are silence and simplicity. On this particular design it is claimed that there are no small parts to be adjusted or inclosed. The line of simplicity is carried out to the cooling and lubrication systems in that a thermo-syphon system of circulation is employed with induced cooling through the center of the rotary valve. This valve is kept constantly full of water and since all parts of the valve are in contact with the cooling agent, the danger of unequal expansion and a cracking of the valve is eliminated.



Silent chain drive of the rotary valve at one-half crankshaft speed



Disassembled view of the valve mechanism of Van Keuren motor

Master Carbureter Has Multiple Jets

Rotary Throttle Shuts Off Jets for Varying Mixture

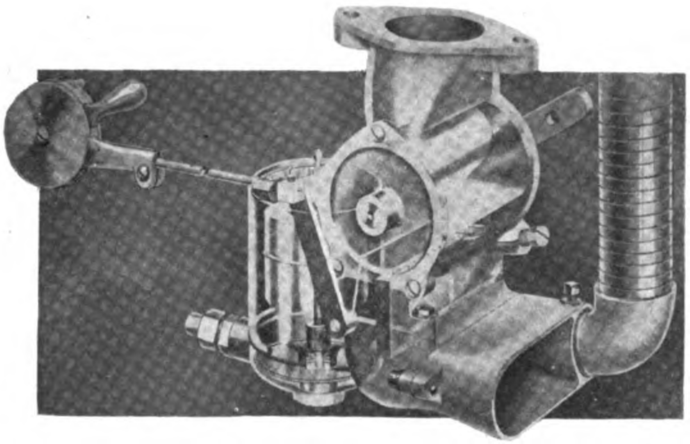


Fig. 1—Phantom view of Master carbureter made by Master Carbureter Corp., Los Angeles, Cal

THE Master Carbureter Corp., Los Angeles, Cal., which recently began manufacturing operations in Detroit in order to market its product in the heart of the automobile field, in addition to continuing its manufacturing for the Pacific Coast States in the California city, produces a simple type of mixing apparatus with no adjustments, which is perhaps not as well known to the eastern and mid-western automobile public as some of the carbureters which have been made in this section for some time.

Three Moving Parts

The Master carbureter, which is shown sectionally in Fig. 2, and a phantom view of which is seen in Fig. 1, differs from the conventional carbureter in that it has a rotary throttle and a multi-jet fuel distributer. These are seen at T and J in Fig. 2. There are three moving parts to the instrument, namely, the throttle, the air damper which serves to shut off a portion of the air coming through the air intake when it is desired to enrich the mixture, and the float. The flow of gasoline from the supply to the float chamber is controlled in the usual way by means of a metal float controlling the position of the needle valve with respect to its seat.

These carbureters are furnished in all sizes from 3-4 inch to 2 1-2-inch manifold connection.

In this carbureter both the fuel and the air are positively regulated, the amounts of each being apportioned mechanically by the rotary throttle. Fig. 3 shows the relation of the throttle to the multi-jet distributer. The throttle T is mounted horizontally on bearings and within the outer body of the carbureter and directly above the fuel distributer. It has openings in its upper and lower sides which are so shaped as to expose more and more of the jets along the length of the distributer as the throttle is rotated by the operation by the driver of the accelerator or the throttle lever. As the additional jets are exposed, more opening to the intake manifold is made, due to the upper aperture in the cylinder. Thus the amount of carbureter opening is in proportion to the jet opening.

When the throttle is fully open there are no restricted passages and the full gas charge is admitted to the combustion chamber, with minimum resistance, supplying all cylinders with equal quantities of gas. All the jets are then open.

To regulate the amount of air flowing up through the air passage and passing the series of jets, an air damper, extending entirely across the passageway and paralleling the fuel distributer, is provided. This is simply a rigid plate, rotating about its lower edge, and controlled from the dash. This damper is shown in Fig. 3 and also at D in Fig. 2. It may be regulated to restrict the air passage on its side of the jet as much as desired, shutting off entirely if desired. This gives a richer mixture for starting purposes, the most economical running position being when it is swung over against the side of the mixing chamber and giving free passage for the air. For ordinary normal running it should be set at about mid-open position, but, of course, this depends entirely upon atmospheric and other conditions.

Throttle Cannot Become Worn

Mechanically, the Master is well designed. The rotary throttle cannot become worn since it does not touch the throttle chamber in which it rotates. Neither does it come into actual contact with the distributer. It operates entirely upon the rather large journals at either end. As a precaution against dirt getting through and into the jets, a double filtering through screens of fine mesh is employed. One screen is below the intake needle valve at the bottom of the float chamber and the other screen, of tubular shape, is inserted in the float chamber and through it the fuel must pass before entering the multi-jet distributer.

As shown in the detail, Fig. 3, the fuel gets to the series of jets in the distributer through a main duct running horizontally along the lower part of the distributer. This connects with the passage to the float chamber.

Semi-Hot-Air Intake

The Master carbureter is, in standard form, fitted with a semi-hot-air intake. At one side of the part which connects through flexible tubing to a hot-air scoop fastened to the exhaust pipe is the opening to the air. It may also be fitted for all hot-air intake if the installation requires it.

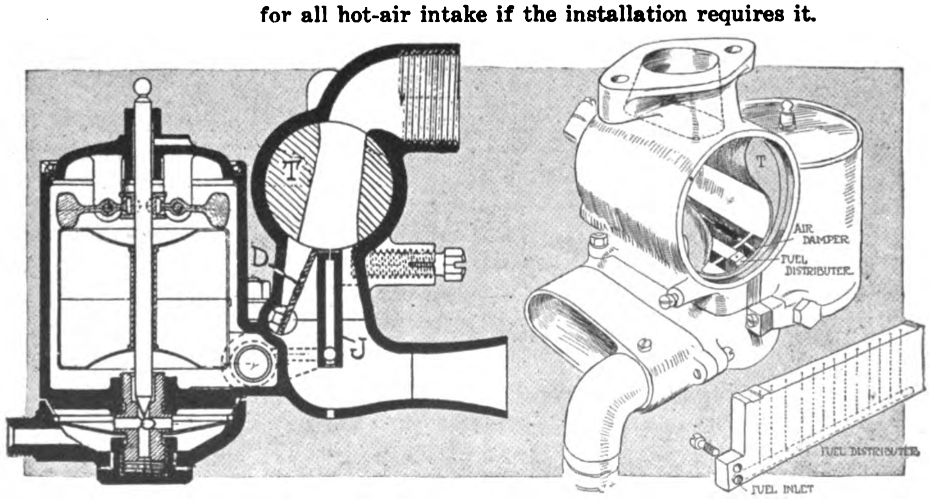

Fig. 2—Left—Section through Master carbureter. Right—Illustrating rotary throttle and location of multiple distributing jets. Fig. 3—Detail—Removable multiple jets

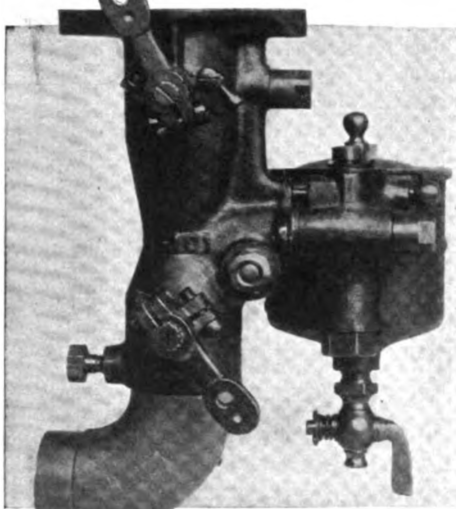

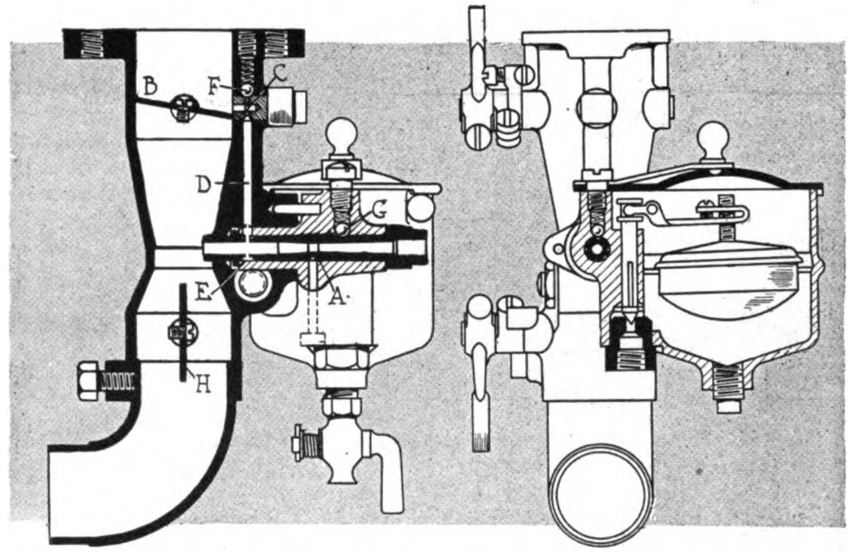

Left—Zephyr carbureter with vertical venturi. The nozzle tubes are plainly visible. Right—Section of carbureter showing nozzle tubes at the left and float mechanism at the right

Zephyr Carbureter Has Adjustable Jets

No Auxiliary Valves or Springs—Venturi May Be Horizontal or Vertical—Easy To Take Apart

SEVERAL notable features are found in the new Zephyr carbureter brought out by George A. Breeze, Detroit, Mich. No air valves, springs or weights are used, but perfect carburetion at all speeds is obtained, it is claimed, by the use of a low and high speed jet.

On open throttle the gasoline on flowing from the float chamber is sucked through the atomizer A, where the fuel is mixed with air flowing in through the jet tube as indicated by the arrow. The fuel is broken up and thoroughly atomized at this point so that when it mixes with the main column of air at the throat of the venturi tube a dry, homogeneous mixture is formed, it is stated.

When the throttle B is closed the mixture is greatly enriched by the major part of the atomized fuel, which is produced at A, being transmitted to the other side of the throttle butterfly by passing through the throttling jet C, which connects with the atomizing tube by means of the passage D and the orifices E. Thus a very rich mixture is delivered to the motor through the throttling jet and but a small amount of fuel passes out to the venturi where it is picked up by the small quantity of air flowing up past the throttle.

Adjustment by Changing Jets

The adjustment of the carbureter is accomplished in a unique manner, the throttling tube C and the atomizing tube A are provided with four jets of different sizes placed at right angles to each other; only the bottom jet, however, is operative as it is the only one registering with the fuel passage. But any jet may be brought to this position as the tubes can be rotated, the outer end of each tube being squared to take a wrench. The tubes are normally held against rotation by means of the spring-engaged ball locks indicated by F and G. The jets in the atomizer are designated by the numbers 1, 2, 3, and 4, the latter being the largest, and the openings in the throttling jet are told by the letters A, B, C, and D. The throttling tubes are made in different sizes, the smallest jet in one tube being the same size as the largest jet in the next smallest tube. The difference in the variation of the throttling jets need not be so close as with the atomizer jets as they regulate mixture and not pure fuel. Easy starting is secured by closing the shutter H, which increases the suction on the jet.

A feature of the Zephyr is that the float feed mechanism can be inspected while the motor is in operation by removing the cover to the float chamber. This is done by merely rotating a small arm, which holds the cover in place. The three moving parts of the float mechanism can be instantly removed for inspection by pulling out the pin that carries the float arm. A line in the casting shows the proper fuel level. Removal of water or dirt is accomplished by opening the pet cock at the bottom of the float chamber. Complete inspection and thorough cleaning can be accomplished in less than 3 minutes, it is stated.

The atomizer gives a range of adjustment sufficient for all temperatures and grades of fuel but cannot be set so far out of adjustment that the engine will not run.

The Zephyr is so arranged that the venturi can be placed

Purity Electric truck with two-speed sliding gearset

Purity Electric Truck Has Two Speeds

Made in Minneapolis, It is Designed for Snow and Sand — Motor, Sliding Gearset and Rear Axle in Unit—Has Worm Drive

A TWO-SPEED sliding gearset placed between the motor and the rear axle is the most notable feature incorporated in the Purity electric truck, built in capacities of 1 and 2 tons. These vehicles were especially designed to conform to the weather conditions of the Northwest, the lower gear being for the heavy snowfalls and sandy stretches of road which render the ordinary electric unsatisfactory.

The two-speed gearset is a unit with the electric motor and the rear axle, the latter being a floating design equipped with worm drive. The unit is carried on a triangular subframe which is attached to the axle at two points and pivoted to a cross-member of the frame at the apex, by a single globe joint.

These machines have been constructed by the St. Paul Bread Co., St. Paul, Minn. Although primarily intended for the use of the Purity company the shop equipment will enable it to accept outside orders. The designer is H. R. Kelly, formerly with the Studebaker Corp.

The frame is of pressed steel of uniform section, bottlenecked in front and braced rigidly. It is suspended from the Timken front axle and the worm-driven rear unit by four semi-elliptic springs. Both sets of brakes are on the rear wheels, and solid tires are employed.

The control is by a steering wheel on the left side, two pedals for the two sets of brakes, a lever in the center to operate the controller, and a lever to the left for the gearset. The dash carries the switch and Sangamo ampere-hour meter. The controller is located beneath the floor, and the electric horn directly beneath the battery box, bolted to a cross-member of the frame.

The battery trays are located under the driver's seat and a low box just behind it. Both brake and driving torque and propulsion are taken by the sub-frame which carries the motor and gearset, and are transmitted thereby directly to the middle cross-member of the frame, so that all portions share these stresses.

Both vehicles have 102-inch wheelbases, 36-inch Schwartz wheels, 40 by 2¼-inch front springs and 46 by 2¼ rears, both pairs being made of Vanadium steel, Westinghouse four-speed controllers and Ross steering gears.

Both are built for a 20 per cent. overload. The worm runs on Hess-Bright radial and thrust bearings, and the wheels on Timkens. The motors operate at 1,500 revolutions per minute at 35 amperes 70 volts.

Six-Ton Doane Truck Has Low Platform

LOW-PLATFORM trucks especially designed for the hauling of heavy material, such as stone, machinery, structural steel, boilers and tanks, etc., are built by the Doane Motor Truck Co., San Francisco, Cal.

The frame is just high enough from the ground to provide sufficient clearance for ordinary conditions, thus permitting the platforms, built directly across the frame members, to be within easy lifting height from the ground. The frames are suspended by springs in the usual manner, clearance over the axles being obtained by deep drops in the axles and underslung springs. The drive is by double chains, the front sprocket centers being somewhat lower than the axle centers.

But one chassis model is made, this of 6 tons capacity. It has a total overall length of 20 feet 9 inches, and has a 14-foot loading platform. This platform overhangs the rear axle 4 feet, and without load it is 24 inches from the ground. Under load, the springs depress to bring it to within 22½ inches from the ground. The load distribution is 80 per cent. over the rear wheels and 20 per cent. on the front wheels.

The frame is of I-beam rolled stock with channel cross-members, made up rigidly, and, although horizontally straight throughout its entire length, it is bottle-necked in front to provide steerage-way for the front wheels.

The front springs are shackled, but the rear springs bear on friction pads. The wheelbase is 14 feet 9 inches, with a 68-inch front tread and a 98-inch rear tread. Tires are 38 by 6 both front and rear, the rear tires being dual. The exceptionally wide tread in the rear gives a loading platform between the wheels of approximately standard width.

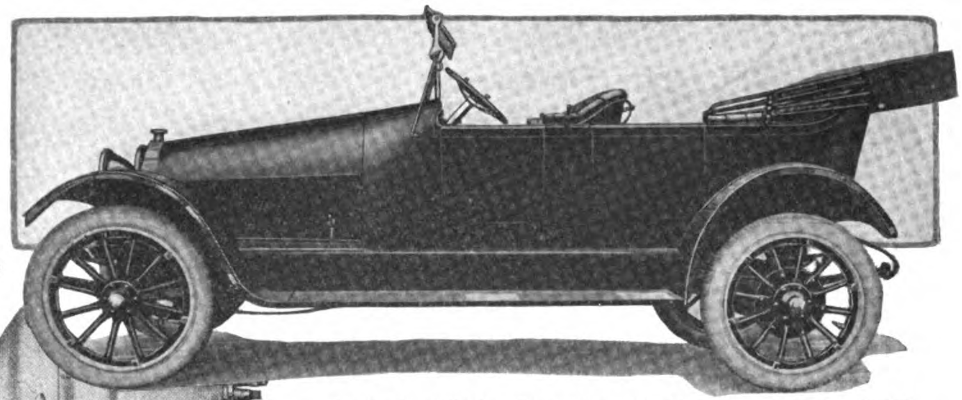
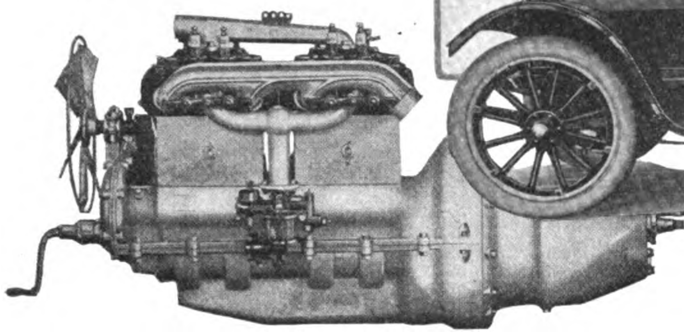
1915 Meteor Six Sells for $1,375

Has Five-Passenger Body—Four Sells for $1,050—Standard Parts Throughout Both Models



New six-cylinder five-passenger Meteor selling for $1,375



Unit power plant used in four-cylinder Meteor

THE feature of the Meteor line for 1915 will be a light six, rated at 45 horsepower and selling for $1,375. It is equipped with a five-passenger body and has a 126-inch wheelbase. Accompanying this model will be a light four, rated at 32 horsepower and listing at $1,050. Both have very full equipment, including an electric starting and lighting system. These cars are made by the Meteor Motor Car Company, Piqua, Ohio.

The only change of note in either of these models is a reduction in the bore of the four-cylinder motor from 4 inches to 3.75 inches, but as a higher speed motor is now used no reduction in power but rather a slight gain is claimed.

With this change the bore and stroke of both motors are the same, 3.75 by 5 inches, and all parts, except the crankcase, camshaft and crankshaft, are interchangeable. The motors are of Beaver make.

The general body lines of both cars are the same, the differences being due to variation in size of the two models. Several minor improvements are noted in these bodies. The running boards have been cleared and the body lines are more truly streamline than heretofore. To gain this end a sloping hood is used which forms an unbroken line with the cowl. A divided windshield of the clear vision type is fitted.

Left Drive Center Control

Left side drive with center control is found and all instruments are neatly mounted on the cowl. The finish of the body is dark blue with black fenders and hood. The metal parts are enameled black and trimmed in nickel. Deep turkish upholstery is employed and the top and dust cover are made of mohair. An electric headlight dimmer is a feature of the equipment, and an electric horn is fitted. The weight of the four is 2,350 pounds and the six weighs 2,950 pounds. The wheelbase of the former is 114 inches and the latter 126 inches. Thirty-two by 3.5-inch non-skid tires are standard equipment on the smaller car, while the larger one has 35 by 4-inch tires.

800 Miles Per Gallon of Oil

The L-head type of motor is found on both models, the cylinders being cast in pairs. This is in unit with the clutch and gearset and the whole is suspended on three points. The valves are inclosed and are situated on the left. The oiling system is a combination splash and pressure feed, a gear pump forcing the oil to each of the main bearings from whence it overflows into the connecting-rod troughs to be splashed by the connecting-rods to the cylinders, pistons and camshaft bearings. From these troughs the lubricant flows back to the reservoir, where it is again put into circulation by the pump. It is claimed that it is possible to go 800 miles on a gallon of oil under average conditions and that as high as 2,000 miles have been covered.

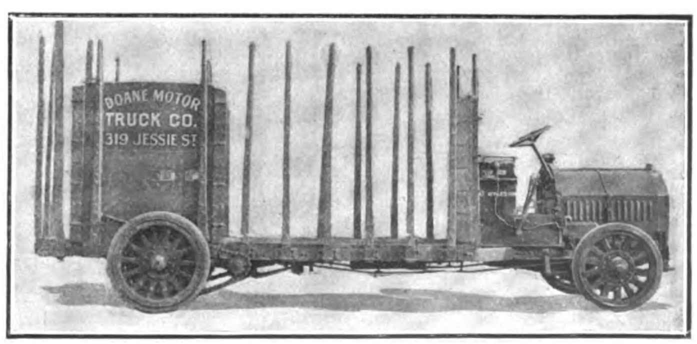
Ignition is supplied by an Atwater Kent system and the carbureter is a Stromberg. The Apple starting and lighting system is used. Cooling is maintained by a honeycomb radiator and a centrifugal water pump.

Clutch Is a Single Disk

The clutch is a single disk type, faced with Raybestos, and running in oil. A feature is the lightness, the whole rotating mass only weighing 8 pounds, therefore gear shifting is greatly facilitated. The clutch is housed in the flywheel, which in turn is inclosed in a bell-shaped extension of the crankcase. The gearset is bolted to this member. There is a hand hole in the top of the clutch case to enable inspection and adjustment. The clutch and gearset are manufactured by the B-T-K Gear and Engine Co. The universals are of Acme make and Salisbury axles are used at both front and rear. The springs are of Sheldon manufacture and Salisbury wheels are used. The bodies are from the factory of the Union City Body Co.

Seventeen New Indian Refining Stations

NEW YORK CITY, Sept. 4—By September 1 the Indian Refining Co., New York City, completed seventeen new stations. Indiana has the greatest number of them, there being seven recently completed in the "Hoosier" state. Illinois ranks second—there are five new stations in Illinois. New York and Minnesota have two each, while Kentucky has one.

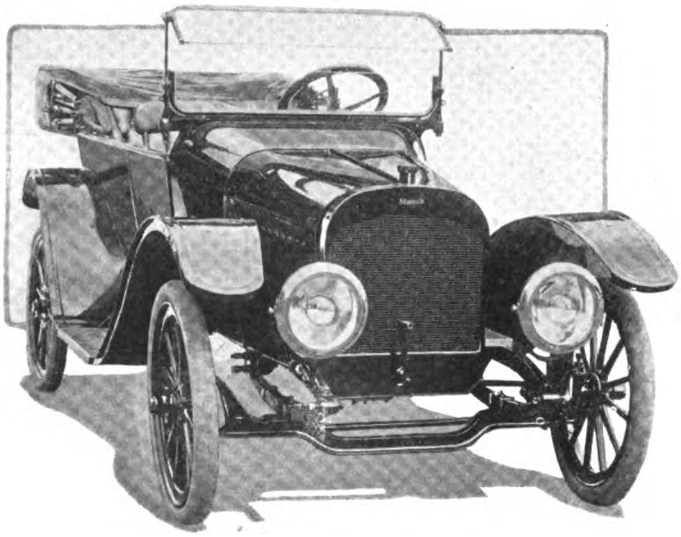


Six-ton Doane truck with low loading platform

Monarch Adds Light Four for $675

New Car Has Four-Passenger Streamline Body—One Folding Front Seat—No Rear Doors—20-Horsepower Block Motor—Electric Starter $25 Extra—Novel Fan Drive

THE Monarch Motor Car Co., Detroit, which has for its head R. C. Hupp, well-known in automobile circles of the motor car city, has added a four-cylinder light car to its line. This is a four-passenger machine of unique seating arrangement which has been priced at $675 with full equipment except electric cranking. The latter feature may be had also at an additional cost of $25.



Front view of streamline four-cylinder Monarch

Streamline Body

The body is a full streamline type and has creditable unbroken smoothness from front to rear. Outwardly it possesses somewhat the same appearance as its larger brothers of this make, though considerably smaller, of course. However, there is ample seating accommodation for four passengers.

There are no rear doors to the body, and the right front seat is made so that it will fold up and allow room for passage into the rear compartment. The left front seat which the driver occupies is stationary, however. This arrangement is rather unusual, but is nevertheless very meritorious in a small car.

Standard Construction Throughout

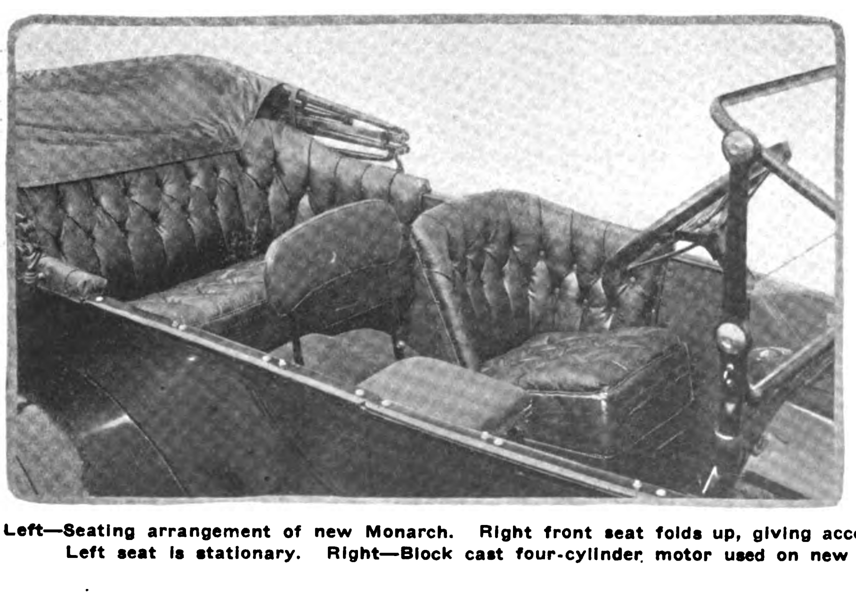
The wheelbase is 103 inches and with standard tread of 56 inches the car conforms to standard mechanical construction throughout the chassis. The motor is a thermo-syphon water-cooled block cast four of 2 3-4 inches bore and 4 1-2 inches stroke. These dimensions give it a horsepower of about 20 which is ample for the car weight—in the neighborhood of 1,300 pounds.

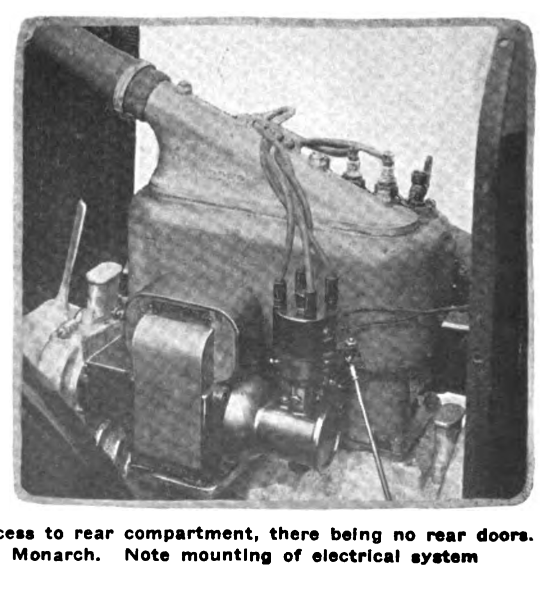
The power plant is of the unit type, incorporating the gearbox as a component part. The whole is three-point suspended, having the single support at the front end on a cross member and the rear two supports by means of a 1 1-4-inch steel tube running through the crankcase just ahead of the flywheel housing and ending in brackets on the side members of the frame. This gives a light and strong support.

The crankcase is of the barrel form and the cylinder block bolts to it. A plate at the bottom gives access to the connecting rods and bearings. Valves and manifolds are on the right side, and two cover plates inclose the tappets and springs, which are of conventional construction. Crankshaft and camshaft are of drop forged steel and each is supported by a large main bearing at either end. The timing gears are completely housed at the forward end.

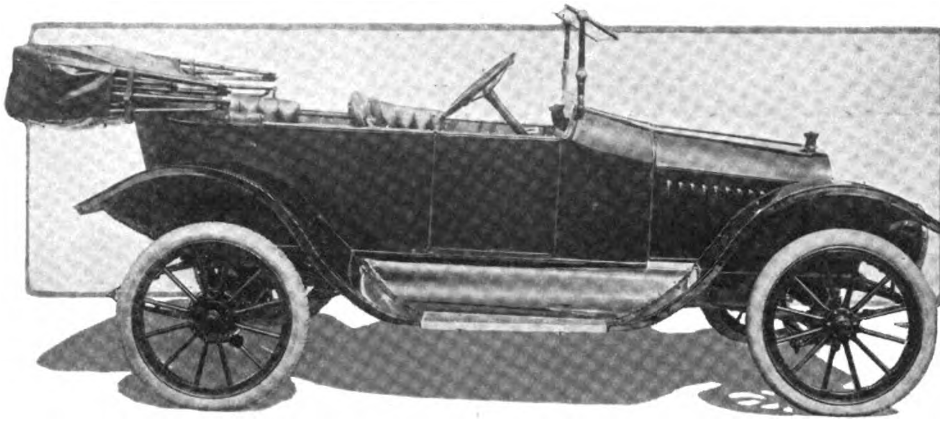
New Type of Fan Drive

An uncommon feature in connection with the front gears is the drive of the fan. This is by inclosed gear also, the idler gear shaft being extended through the case, and on it the fan is mounted. This does away with any kind of external belt drive for the fan and, since there is no extra gear used for the fan drive, makes a very good construction without complication.





Left—Seating arrangement of new Monarch. Right front seat folds up, giving access to rear compartment, there being no rear doors. Left seat is stationary. Right—Block cast four-cylinder motor used on new Monarch. Note mounting of electrical system



Side view of new four-cylinder Monarch light touring car. Note absence of rear doors, gasoline tank and cowl and streamline body

The lubrication of the motor is of the splash type with the level in the troughs under the connecting-rods maintained by the automatic method, the air seal within the crankcase preventing more than the required amount of lubricant being drawn up from the reservoir and delivered to the troughs.

The carbureter, a float feed Zephyr make, is mounted high on the right side of the cylinder casting, having a very short intake pipe. There is only one opening into the casting, the distribution to the various cylinders being taken care of within the casting itself. The carbureter position is made possible, due to the placing of the gasoline tank in the cowl, assuring direct gravity feed. The tank has 8 gallons capacity with a 2-gallon reserve.

The Auto-Lite generator with which the new Monarch is regularly equipped is placed on a bracket on the left side of the engine and drives through gear at the front end. The ignition distributer is in unit with this generator and is of Connecticut make. Its current comes from the storage battery.

Ward Leonard Starter $25 Extra

The cranking motor is of the Ward-Leonard make, and is arranged to gear to the flywheel through a Bendix drive. That is, when the current is thrown on, the pinion automatically engages with the flywheel teeth, and as soon as the motor operates under its own power, automatically disengages again. The electric motor, which has a reduction of 15 to 1 as compared with the crankshaft speed, turns the latter about 130 revolutions a minute. The storage battery is a Willard. In instances where the car is ordered without the starting motor, it is pointed out that the engine is so arranged that this cranking feature may be added at any subsequent time since the battery is amply large to take care of the starter.

Three Speeds Forward

The gearbox, bolting to the flywheel housing, has three forward speeds and reverse and power comes to it from a multiple disk clutch within the flywheel. This has its disks alternately of steel and Raybestos lined. The drive shaft is open and has two universal joints. The drive is of the same form as used on the other Monarchs in that torsion members parallel the shaft on either side from a mid-cross member back to the axle housing.

Gearless Differential Used

The rear axle is light and strong. It is of the gearless differential type. That is, instead of having the usual spur differential gears within the bevel ring gear, there is a member of the gearless differential at either rear wheel. These members are fitted with a form of roller clutches which have the same action as the usual gears in allowing one wheel to turn faster than the other for rounding corners or under other circumstances. However, these roller clutches insure positive drive to both wheels in accordance with their traction. The gearless differential has been described on a number of occasions and has proven very successful in a number of installations on different cars.

Brakes are of conventional type and act on 8-inch drums. The wood wheels used are of twelve-spoke type and carry clincher rims on which 30 by 3 tires are mounted, the rear pair being safety treads.

Steer and Center Control

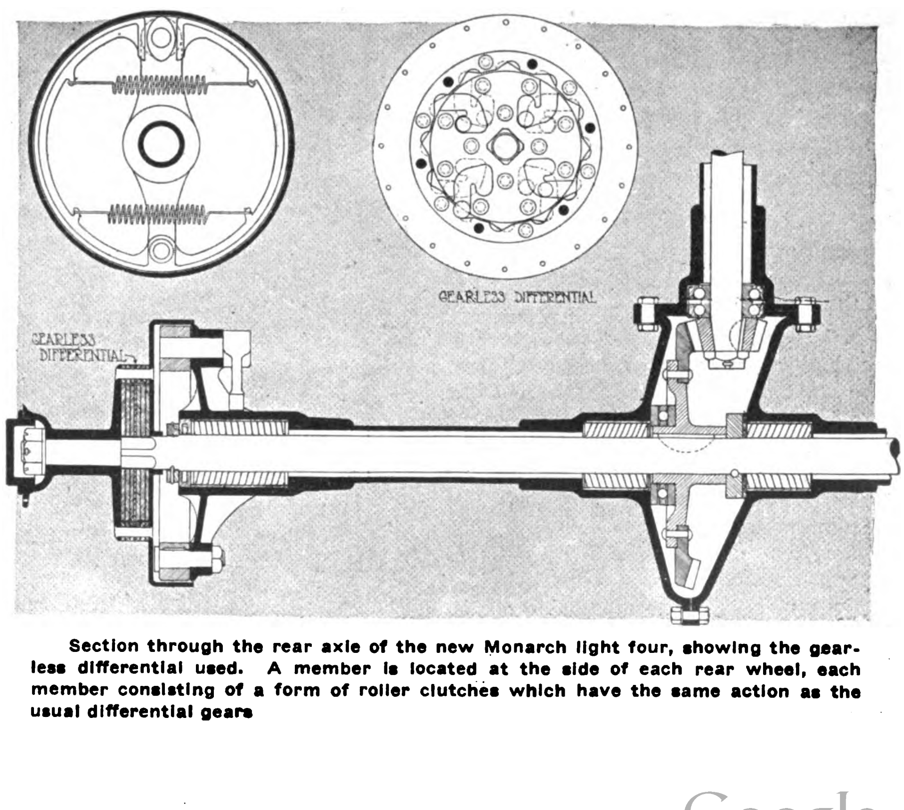
Steering is on the left and control in the center. There is nothing departing from the standard in the operation of the car. Even the usual quadrant above the wheel with spark and throttle levers is found.

The pressed steel frame is suspended by half elliptic springs in front and elliptics in the rear. These latter are swiveled on both axle and frame, and their free action tends to easy riding. The leaves are 1 1-2 inches wide, and lengths are 33 and 38 inches, front and rear, respectively.

Equipment in addition to that already mentioned includes one-man top and curtains, envelope, electric horn, rain vision windshield, Stewart speedometer, tools, repair kit, pump and jack.

International Races at Corona Thanksgiving Day

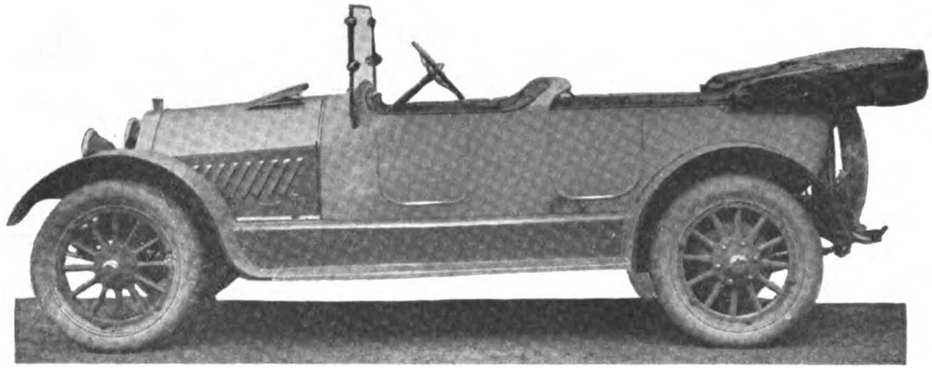
CORONA, CAL., Sept. 4—Definite plans were made recently for holding the international automobile races here on Thanksgiving Day. Purses amounting to $17,000 will be offered in the 250-mile and 30-mile races.



Section through the rear axle of the new Monarch light four, showing the gearless differential used. A member is located at the side of each rear wheel, each member consisting of a form of roller clutches which have the same action as the usual differential gears

McFarlan Sixes 300 Pounds Lighter

Two Motors—One Chassis—Wheelbase 4 Inches Longer—Stewart Gasoline Feed Adopted—New Arrangement of Control Levers



New McFarlan six with hood ventilator, and clean running boards

SEVERAL important changes have been made in the 1915 models manufactured by the McFarlan Motor Car Co., Connersville, Ind. As heretofore, two chassis will be built, or rather one chassis with two sizes of motors, the larger having a bore and stroke of 4.5 by 6 inches and the smaller, 4 by 6 inches. The former sells for $2,900 and the latter for $2,590, both equipped with open bodies.

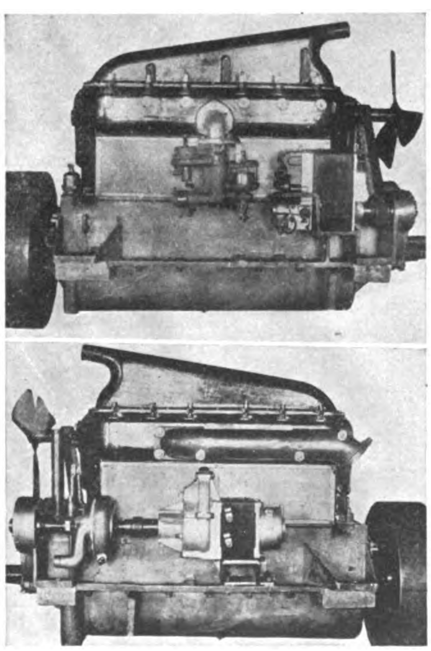
The most important changes which have been made include a lengthening of the wheelbase by 4 inches to 132 inches; a reduction of 300 pounds in weight; the adoption of the Stewart vacuum gasoline feed; a new arrangement of the gear shift and brake levers; the adoption of Westinghouse electric lighting and engine starting equipment; a new cone clutch; new body lines and a new tire carrier. As heretofore, equipment is complete.

In appearance, the new models will be quite a little different from their predecessors, the principal change being due to the lengthened wheelbase. The bodies are longer, as a matter of course, and now are set lower than heretofore. The upholstery does not project above the body lines at any point and the top line extends clear around practically without a break. Another distinctive feature is the addition of a miniature cowl at the back of the front seats. In addition to affording a measure of protection to those who occupy the tonneau, this cowl also serves a practical purpose in that it houses a small compartment suitable for goggles, gloves, etc. At the same time, the extra seats in the tonneau fold down beneath this compartment in such a way that no part of them projects into the doorway.

Few Mechanical Changes

Mechanically, not a great number of changes have been made, the more important ones being the adoption of the Westinghouse electric lighting, starting and ignition system and the substitution of a light cone clutch for the multiple disk member that has been used in the past. Although the Westinghouse apparatus now is standard equipment, the McFarlan pneumatic starter will be fitted where specified.

The two units of the Westinghouse system are mounted on opposite sides of the motor, the generator being on the intake side and the motor on the exhaust side; both are in accessible positions. The generator unit carries the distributer for the ignition system.



Two views of McFarlan six motor. Note high mounting of the carbureter

All of the wiring of the electric system has been thoroughly enclosed in flexible conduits; there is not an exposed wire on the car; these conduits are both dust and oil-proof.

The adoption of a cone clutch marks quite a departure from previous McFarlan practice and has been done with three objects in view: To simplify the chassis; to lighten the weight; and to provide greater holding surface.

The new member is a 16-inch leather-faced cone, the face being 4 inches wide. Beneath the leather there are twelve flat springs which are adjustable.

In the arrangement of the gear shift and emergency brake levers McFarlan engineers have solved a problem that long has existed. The placing of these two levers in the center of the foot board has not been easy because one is likely to interfere with the other. In the McFarlan arrangement, however, there can be no interference.

The gear shift lever is placed directly between the front seats and does not extend above them. Thus, it can never be in the way. The brake lever is quite separate and is set well forward where it, too, is out of the way though it is instantly available.

Although the weight of the car has been reduced by as much as 300 pounds, this has not been done by sacrificing the factor of safety. The chassis has been practically unchanged. Instead, the improved body construction throws part of the strain upon the metal parts of the framework, with the result that bodies now are much lighter than heretofore.

Another little change in construction, designed for the convenience of the owner, is the adoption of a new style tire carrier. As heretofore, the spare tires are carried at the rear of the body but instead of being held by four straps which must be loosened, but one is used.

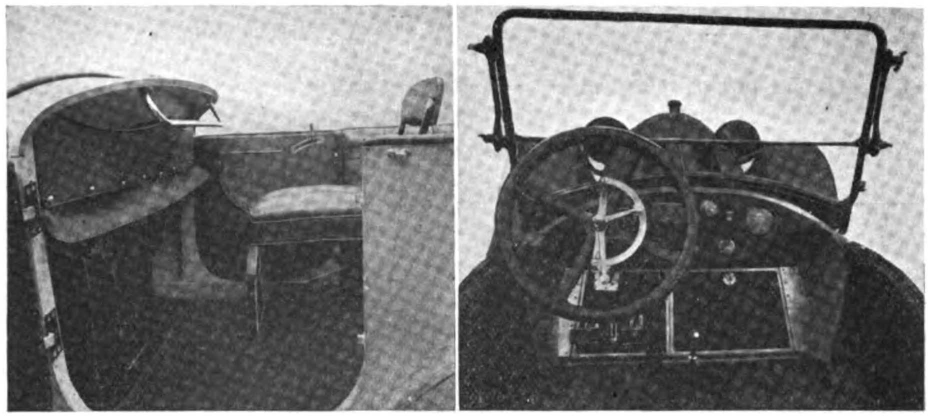
The two motors differ only in size. The cylinders are T-head block castings. The intake is on the right and the exhaust on the left. The intake manifold is noticeable in that it is nothing more than a short L-shaped fitting that connects with the carbureter and the cored passage in the cylinder casting. Thus the position of the carbureter is high and accessible. The exhaust manifold is separate from the casting. Water circulation is by a centrifugal pump situated on the left and the system is distinguished by the large size of the water manifolds.

The gearset is located on the back axle, the latter being a full-floating design. The drive shaft is housed in a torque tube which is reinforced by triangular rods running to the ends of the axle housing. Access to both gearset and rear axle is obtained by the removal of cover plates.

The tires are 36 by 4.5 inches all around and the frame is suspended on half-elliptics in front and three-quarter elliptics in the rear. The frame is heavily reinforced at the corners with gusset plates and is slightly narrowed in front to give increased steering radius.

The equipment is complete, including not only the usual top, curtains, and windshield, but also Hartford shock absorbers, Warner speedometer, power tire pump, headlight dimmer, cigar lighter, Klaxon horn, detachable rims, tools, etc.

Three body colors are offered, blue black, emerald green, and golden brown. Four different bodies are placed on each chassis, the prices being as follows for the smaller and larger cars respectively: Touring car and roadster, $2,590 and $2,900; 4-passenger coupe, $3,300 and $3,610; limousine, $4,000 and $4,310.



Left—Tonneau, showing compartment into which auxiliary seats fold. Right—View of cowl and control showing the arrangement of the levers—the brake lever is set forward out of the way and the ball-handled gear lever is placed between the seats

Zephyr Carbureter Has Adjustable Jets

(*Continued from page* 497)

horizontally or vertically, as is desired. The air intake fitting can be put at any angle also.

The adjustment of the carbureter is simply accomplished by setting the atomizer and throttling jet tubes so that the nozzles A and C, respectively, are in operation. Then regulate the throttle stop screw until the motor idles as low as desired.

If the motor misses or stops, provided that the trouble is not mechanical or electrical and there are no air leaks in the manifold connections, the jet is too small. But if the motor misses and loads up, the jet is too large.

After the motor is warmed up, try driving with larger and smaller jets in the atomizer and use the adjustment found to be best.

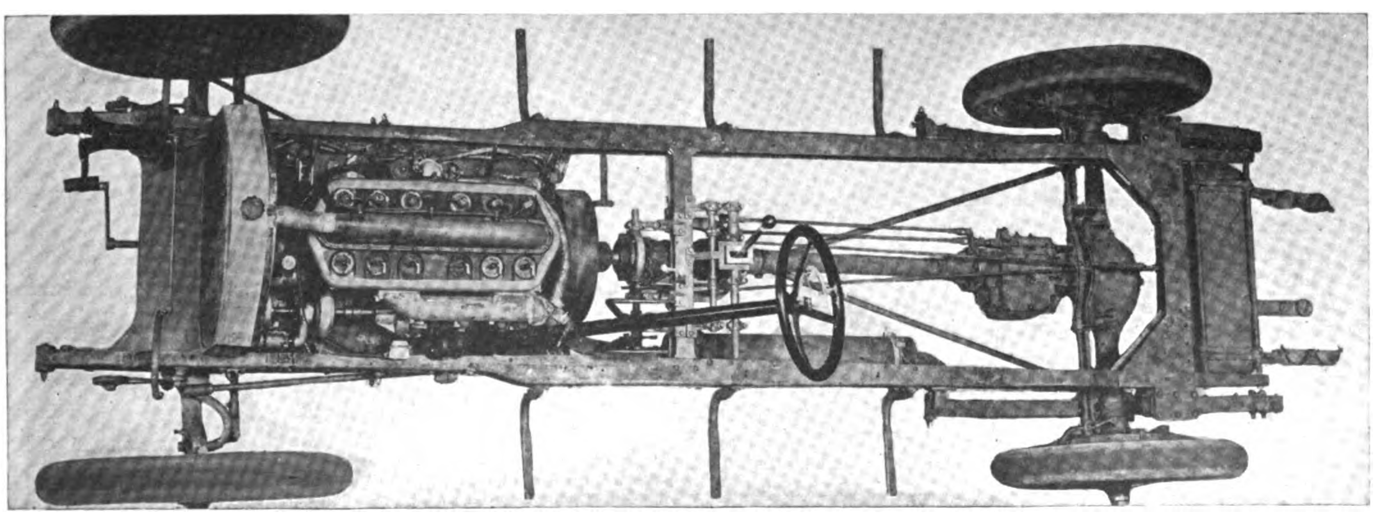
When no setting makes any apparent difference in this, look for manifold leaks, spark plug or magneto trouble.

A steering column control of the starting shutter is furnished when desired.

Farmers Own One-Third of Wisconsin's Cars

MILWAUKEE, WIS., Sept. 7—Thirty-six per cent. of the 50,000 odd motor cars owned in Wisconsin belong to farmers, while 64 per cent. are in the hands of persons living within the limits of incorporated cities and villages, according to a compilation made by Ex-Gov. W. D. Hoard, editor of *Hoard's Dairyman*, Fort Atkinson, Wis. The basis of the calculation is the schedule of assessors in forty-one counties in Wisconsin which are considered agricultural districts, and does not include Milwaukee county because of the preponderance of city population over rural population, which is in the ratio of 97 to 3. Governor Hoard's figures show that one city family in every twelve and one farm family in every twenty-two owns a motor car. In Milwaukee county the ratio is 1 to 16 city families and 1 to 15 farm families. The richest farm county from the standpoint of number of cars is Walworth, in which one farmer in every nine owns a machine. The number of machines has a close relation to farm values. In Walworth county, for instance, farms have an average value of $13,000, while in a northern county like Shawano, where there is one machine to each thirty-seven farms, the average farm value is $6,000.

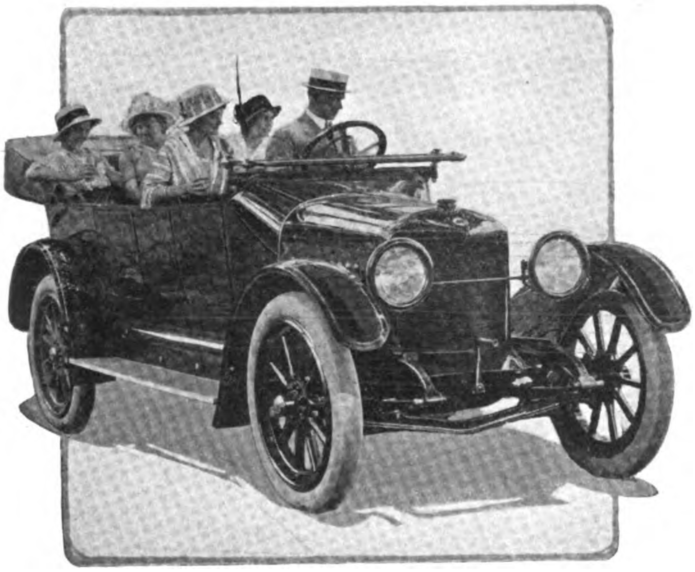
WASHINGTON, PA., Sept. 7—The plant of the Croxton Motor Car Co. has been sold to the Angldile Computing Scales Co., Elkhart, Ind., for $52,500. The new company, as soon as possible, will remove its equipment here.



Plan view of the chassis showing the general arrangement of the units. The frame is narrowed at the front and the corners gusseted

Streamline Bodies on Premier-Weidely

Six-Cylinder Weidely Type Unit Power Plant Continued Practically Unchanged—Three Bodies



Three-quarter front view of 1915 five-passenger Premier-Weidely six

FOLLOWING practically the same design as for the 1914 season, the 1915 Premier-Weidely has been continued with a few detail changes. This motor which made its appearance in December, 1913, excited immediate comment because of the fact that it employed the advantageous valve-in-the-head design and at the same time eliminated the rocker-arms and push-rods which are generally incorporated with this type of valve action.

Unit Power Plant Is Simple

For this season the Premier-Weidely will be made in five- and seven-passenger touring models and a roadster design of body. The price on all three styles is $2,700. While the bodies employed are the latest type in design and equipment, it is in the power plant that chief interest centers in this car. The motor has six cylinders, cast in a single block with a bore of 3.625 and a stroke of 5.5 inches. The valves are all located in the head and are driven by an overhead camshaft. They are without cages and are operated by the single camshaft which is located above the cylinders and which is driven directly from the crankshaft by a vertical shaft and a worm gear. The entire cylinder head is a single unit as well as the cylinders proper. This cylinder head carries the valves and the camshaft and is provided with an additional cover plate which forms an oil-tight housing for the valve mechanism. By this scheme of completely inclosing the valve action, the entire drive can be copiously lubricated and, in fact, runs in a bath of oil.

A glance at the exterior portion of the motor shows it to be of remarkably clean lines. Even the water pipes have been eliminated and the radiator bolted directly to the motor, making the two units an integral part. The intake manifold is cast in a unit with the cylinders and the carbureter bolts directly against this unit manifold, giving it an extremely high and accessible position. This method of construction makes a motor of very simple and clean appearance.

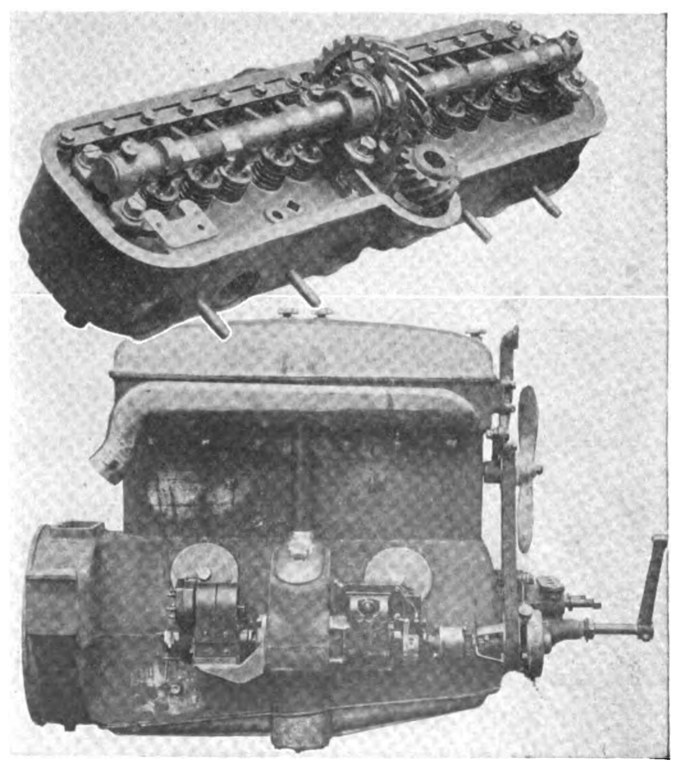
Overhead Valves of Large Diameter

Considering their location in the head, the valves are of large size, having an outside diameter of 1 15-16 inches and a diameter in the clear of 1 21-32 inches. The valves seat directly in the head casting and each valve overhangs the cylinder bore slightly so that in the event of a stem breaking, the valve could not fall into the cylinder. There are no rocker arms used. The camshaft is directly above the valve and the cams act on a light steel follower pivoted at one end. This finger lever transmits the motion of the cam directly to the valve. There is an adjustment by means of a nut on the follower which permits of taking of the wear on the valve mechanism. This corresponds directly to the usual valve stem adjustment.

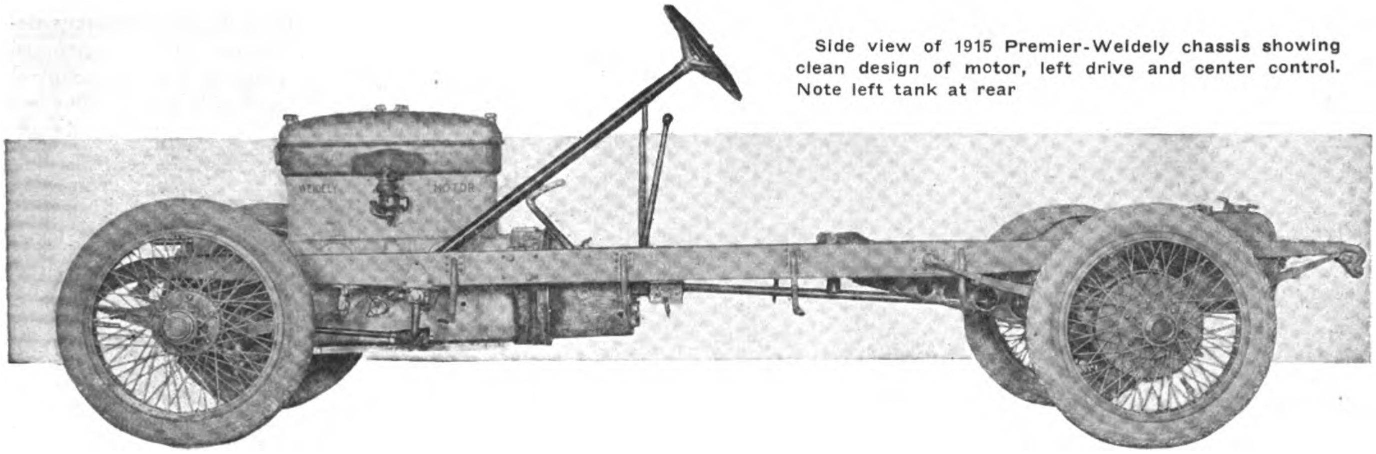
Valve Mechanism Is Unusually Light

The lightness of this valve mechanism is its special feature. By this construction it has been possible to make the valve springs 20 pounds weaker than in the ordinary type of engine. Another advantage gained by the light construction is the noiselessness of operation. To further increase the factor of silence, the complete oil-tight housing and the bath of lubricant also play their respective parts.

The vertical shaft by means of which the drive is taken from the crankshaft to the overhead camshaft is located at the longitudinal center of the engine. This position of the half-time gear gives it a balance which it would not possess if located at one end of the motor. Side thrust is also eliminated by the use of the pivoted finger which transmits the drive from the cam to the valve.



Weidely type of motor used in Premier cars. Above—Detachable cylinder head, showing operation of the overhead valves by a single camshaft driven by gear from the vertical shaft shown at the side of the motor



Side view of 1915 Premier-Weidely chassis showing clean design of motor, left drive and center control. Note left tank at rear

The Weidely motor is distinguished by the cross-head type of piston. This design is so arranged that the part taking the pressure of the gas is separate from that which acts as a guide. As will be seen in the cross sectional view, the piston-head and rings are formed as usual, but there is a slot .25 inch wide between the head and skirt of the piston. The piston boss is connected to the head by means of two crescent-shaped webs. By this arrangement, little or no heat can be transmitted from the head of the piston to the skirt and the head proper is kept cooler. With this piston a clearance of but .0015 inch can be used.

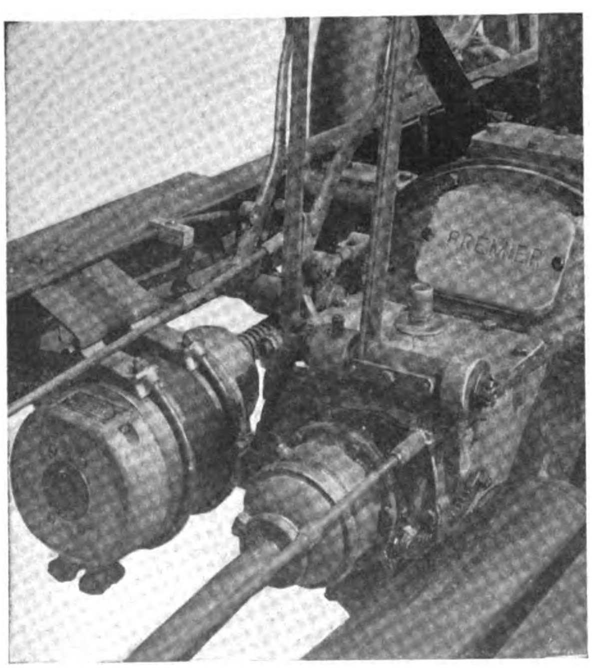
Four-Bearing Crankshaft

The crankshaft is carried on four bearings, the two middle bearings being between the third and fourth cylinders. All the main bearings are 2 inches in diameter, the length being 2 9-16 for the front, 1 5-8 for the center ones, and 3 3-4 for the rear. Connecting-rod bearings are 2 inches in diameter and 1 3-4 inches in length. The gear in driving the vertical shaft is fastened on a flange formed integrally with the crankshaft. The two central main bearings support the crankshaft on either side of this driving gear. The running thrust on the vertical driveshaft is taken by a Timken taper roller bearing.

The camshaft bearings are all solid bushings. There are four of these bearings, supporting the 1 3-16 inch shaft. The end bearings are 1 1-4 inches in diameter and 1 3-4 inches long. The center ones which are mounted on either side of the driving gear are 1 3-4 inches in diameter by 1 5-8 inches in length. A hole 3-8 inch in diameter is drilled throughout the entire camshaft and carries oil to the cams and end bearings.

All Drives Balanced

As for last season the Premier car of 1915 will be fitted with Remy starting and lighting and Eisemann magneto ignition. Following the system of balancing all drives throughout the car, the electric generator for the starting and lighting system is mounted on one side of the vertical shaft which drives the valve mechanism, while the Eisemann magneto is mounted on the other side. On this same shaft, which runs parallel to the crankshaft of the motor, the fan belt pulley is mounted.



Mounting of Remy starting motor on left frame member alongside gearbox. Note center control

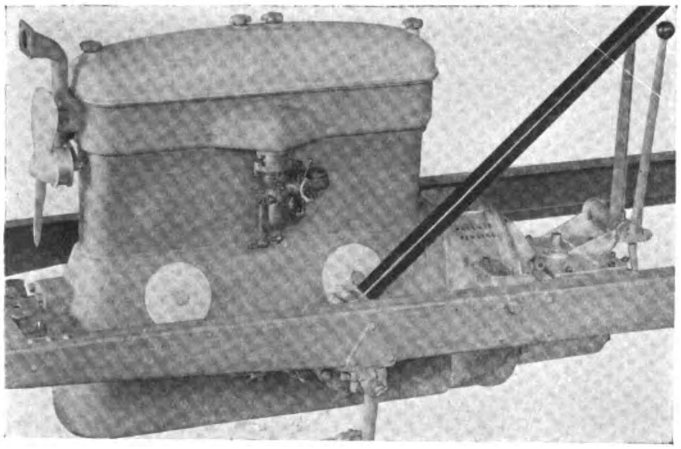
The oiling system of the new motor is a combination of pressure and splash, the oil being circulated by a gear pump bolted to the crankcase and driven from the bottom of the vertical shaft. The oil is distributed by a rotating sleeve on the top of the pump. Equal parts of the oil are sent to each of the six troughs into which the connecting-rods dip through a passage cored in the bottom plate. One part of the oil is carried to the valve mechanism. The camshaft bearing and cams are lubricated by means of the hollow camshaft above mentioned. The entire valve mechanism is bathed with oil by streams that issue from the backs of the cams. The oil is then drained toward the center of the cylinder head and falls back to the crankcase through a hole in the casting. In the center of the cylinder head casting is a well in which the camshaft gear revolves. The oil from the camshaft bearing keeps this filled so that as the gear revolves it is constantly oiled.

Superfluous Parts Eliminated

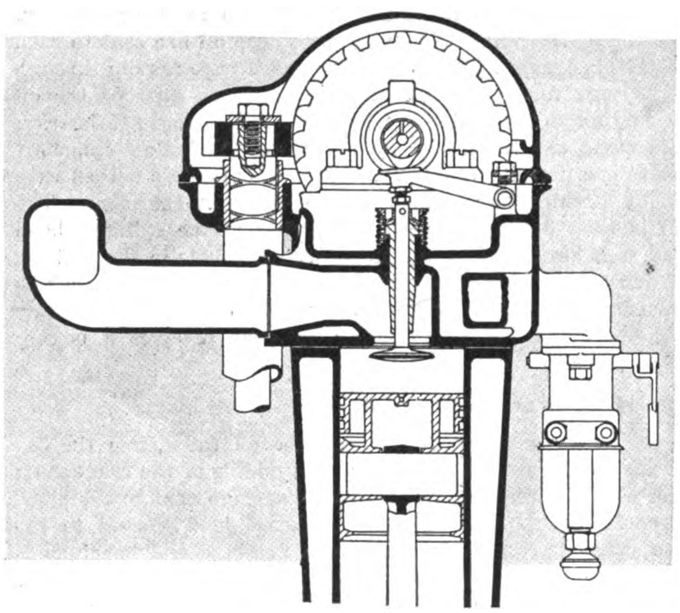
On the way to the crankshaft the oil falls from the top of the motor, strikes the gear in the middle of the crankshaft and also fills the two middle main bearings next to the gear. Troughs on the side of the crankcase lead the oil to the end crankshaft bearing. Leakage at these end bearings is prevented by an oil thrower ring which clears the shaft of lubricant by centrifugal force, sending the oil by a drain back to the main pump, whence it is re-circulated.

One of the striking features of the motor is the elimination of a number of parts by making one member discharge a number of distinct functions. An instance of this is the water pump housing which also serves the purpose of the connecting medium of the radiator to the pump, the pump to the motor, the starting crank bearing support, the radiator support, front motor support and holds the adjustable thrust bearing at the forward extremity of the crankshaft.

The upper water connection has likewise a variety of functions to fulfill. This casting, beside taking care of the water circulation, has a downward projection which supports the fan and provides an adjustment for the fan belt tension. The radiator is supported only by the top and bottom water connections and there is no



Illustrating the clean design of the Premier-Weidely unit power plant. Note the detachable cylinder head and also the high mounting of the carbureter, which is attached directly to the cylinder casting



Cross section through Premier-Weidely cylinder head, showing overhead valves operated by a single camshaft driven by the vertical shaft at the left

rubber hose. The radiator thus has a two-point suspension and is a solid unit with the motor. In fact, the unit idea is carried throughout the entire design of the power plant. It not only incorporates the motor, clutch and gearset but takes in the radiator as well.

22 Miles Per Gallon of Fuel

One of the claims of the Premier company is efficiency for this new type of motor. They state that by the elimination of about 40 per cent. of the moving parts, the motor has been silenced to a large degree and the efficiency increased to a marked extent. It is claimed that the number of miles per gallon secured with this type of motor is in excess of that generally obtained with a six-cylinder car. On a test held through the city streets on a touring model, when the motor was first brought out, an average of 22 miles per gallon was secured, showing the economy possibilities.

Outside of the engine, the Premier-Weidely does not differ greatly from the other Premier designs which have been previously described in these pages. The multiple-disk clutch is continued and the gearset employed has three-speeds with the control lever in the center in combination with left drive. The remainder of the chassis is exactly like the poppet design Premier with the exception that the rear springs are one-half elliptic instead of three-quarters. This has been done to reduce the side sway. The frame has a slight kick-up over the rear axle and is tapered, being 6 inches narrower at the forward end than at the rear to provide a narrow turning radius.

Three Streamline Bodies

The three body designs which are fitted on the standard cars are of streamline design and this, coupled with the V-radiator, gives the car a distinct appearance. The fenders are crowned and the fuel tank is located at the rear, pressure feed being necessary with the high carbureter. The hood is sloping and, being exceedingly short for a six, permits the designer to use the 132-inch wheelbase to advantage in securing space in the body. The tires are 36 by 4.5 inches, the spare being carried in the rear on a support rigidly connected to the side members of the chassis frame.

Overland Factories Rushed—Willys Optimistic

NEW YORK CITY, Sept. 8—Since returning from the war zone, John N. Willys, president of the Willys-Overland Co., has been making conservative estimates of automobile business in America and states that the Willys company is working its entire force all of the time and on a full-pay schedule. The company has 1,000 more unfilled orders than were on its books at this time a year ago, this in spite of the fact that daily shipments are fifty more cars than last year. On September 3 the company had shipped twice as many 1915 cars as it had shipped 1914 models a year ago.

In looking over the country the retail business is generally improving. New York City shows 100 per cent. increase, and large gains are shown in Philadelphia, Boston, Washington, Baltimore, Rochester, Syracuse and many other eastern points.

From other sections of the country good retail reports have been received. There is added business from the grain belts, and while business is poor in the cotton section, notwithstanding the bumper cotton crop, the average conditions throughout the country are particularly favorable.

In speaking directly on conditions in the war zone, Mr. Willys says: "Nearly all of the large automobile factories in Europe were entirely unmanned soon after the opening of hostility. Few cars will be built until these hostilities cease. In the meantime the entire field is open to the American manufacturer. For a time lack of transportation facilities will hamper foreign business, and abnormally high insurance rates will make shipping almost prohibitive. The seas are being rapidly cleared and soon export shipments will increase."

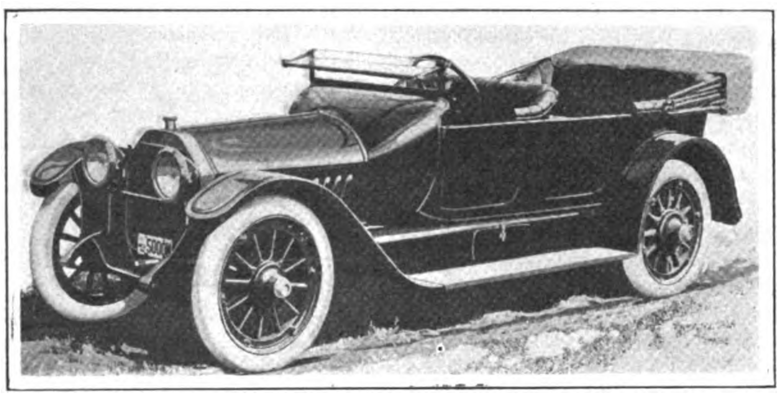
Oldsmobile Continues Four and Six

Cuts Price $60 on Small Car and $175 on Six —Wheelbase Lengthened on Smaller Car

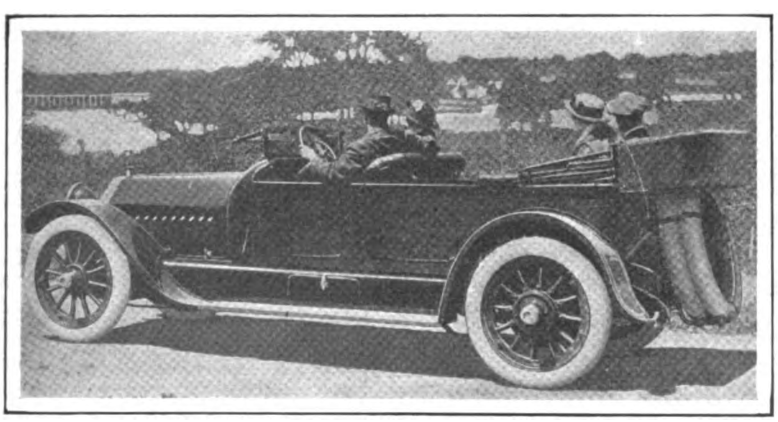
As regards the models which it will produce for 1915, the policy of the Olds Motor Works, Lansing, Mich., is to continue the light four and the big six with very slight change mechanically, though body design, finish and refinement have been brought to an even higher standard and prices have been cut somewhat.

The light four, which made its appearance earlier in the year as the consort of the big six, has been reduced from $1350 to $1285, and besides the touring model, a roadster type has been added to sell at the same figure.

The big six, which formerly was offered in both five and seven-passenger touring types, may be had only in the seven-passenger form now. The old prices were $3150 for the car with seven-passenger and $2975 with five-passenger body, and on the new basis, the seven-passenger type is to sell at the figure which purchased the five-passenger model last season. Thus it is really reduced $175.



Four-cylinder five-passenger touring model



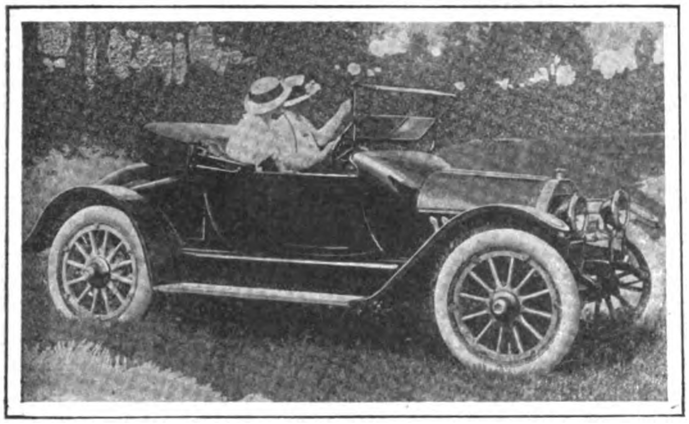
Six-cylinder seven-passenger Oldsmobile

The light four still continues to be a light car *De Luxe*, for its finish and appointments leave nothing to be desired. They are really just as fine and elaborate as accorded the big car. Outwardly the light car appears to be a reduced copy of the six; its lines are about the same, it has the same distinctive panelling along the upper edge of the body, and the hood and radiator have the same general shape on a smaller scale.

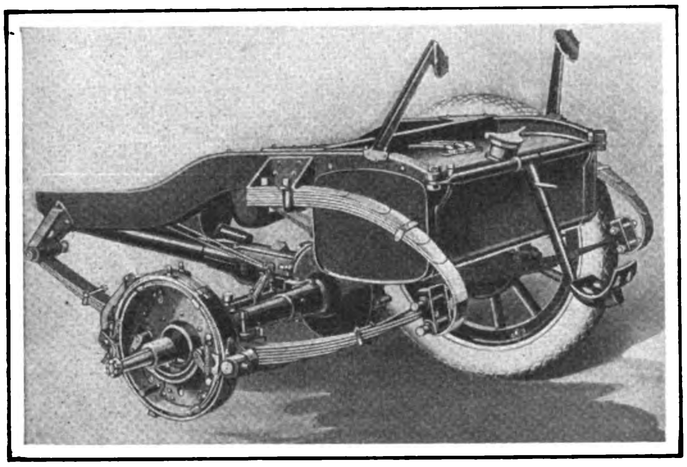
The Light Four Model 42

The principal difference between the light Olds four of today and that brought out earlier in the year is the wheelbase. It has been lengthened 2 inches to 112 inches. This has not affected the body size, but the front axle has been carried forward so that it now is in line with the radiator which formerly was 2 inches ahead of the axle. In addition, the front springs have been lengthened 1½ inches and are now 35½ inches between bolt centers, making a very easy riding car due to this length.

There has been no



Two-passenger roadster body mounted on the four-cylinder chassis



Rear suspension of gasoline tank on the Oldsmobile light four

change in the motor, which is a specially designed valve-in-the-head type by Northway for this car. It is a block-type which together with the gearbox forms a unit power plant of very neat design, compactness and lightness of weight being particularly noticeable.

The cylinders are 3½ by 5 inches, and, though the S. A. E. formula would not indicate it, give the engine a brake horsepower of 30. The piston displacement is 192.33 cubic inches and with these dimensions, the motor has ample power to give all the speed any owner could desire, it being able to turn up close to 60 miles an hour if given a chance. The motor might really be classed as a high-speed type as it develops its maximum power at about 2300 r.p.m.

Perhaps the most unusual feature of this over-head-valve motor is that no part of the long push rods or of the rocker arms, valves or springs, is exposed.

When the aluminum plate is in place over the valve mechanisms and rockers, it is hard to distinguish this motor from one of the conventional L-head types, and this housing of all valve parts also has the advantage of silence.

Delco Electrical System Used

The electrical equipment of the light four has undergone no changes save those minor detail improvements which the Delco concern has deemed advisable for greater reliability, with one exception. This is the addition of the automatic spark advance feature.

The Delco unit which combines the functions of cranking, lighting and ignition is located on the right side of the motor and as a generator it is driven by the same shaft as that which operates the water pump. The ignition distributer is in unit with the motor-generator. As a cranking motor, the unit connects through a train of gears to the teeth in the flywheel rim in the usual way. The reduction between engine and motor is 24 to 1, and the engine is cranked under average conditions at 100 revolutions a minute. As a generator, the apparatus begins to charge at 15 miles an hour. The system is a 6-volt type which uses an Exide storage battery of 60 ampere-hours capacity. This is located under the seat in a special steel container.

Lubrication of the motor is of the splash type with an individual splash trough under each cylinder. The oil is pumped from a reservoir on the side of the crankcase to the oil gauge on the dash and then feeds by gravity down to the troughs and to crankshaft and camshaft bearings. The connecting-rod ends dipping into the troughs throw the oil up into the cylinder walls and to the other bearings.

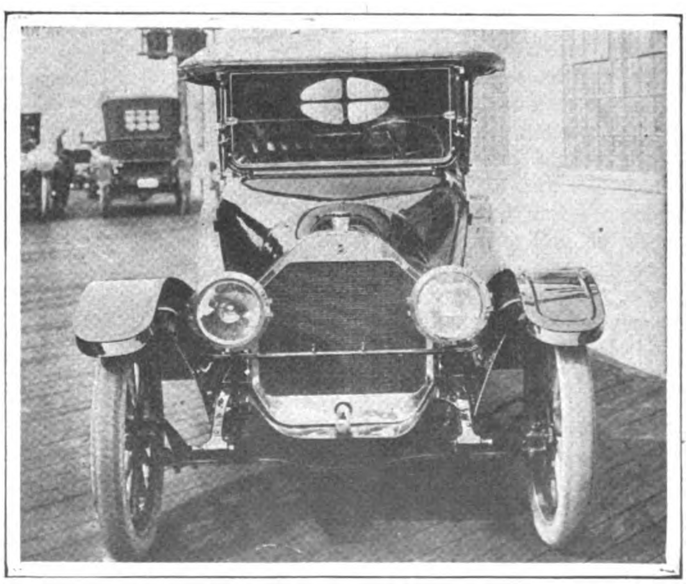
As in the motor unit, no change is apparent in the upper transmitting mechanism nor in the other chassis members. The clutch, which is housed with the flywheel, is of the cone type 12½ inches in diameter with a 2½-inch face and a cone angle of 11 degrees. From here the power goes to the three speed gearset of conventional type which bolts through flange construction to the rear of the flywheel housing and which is arranged for center control. The shaft is mounted on large ballbearings and transmit the power efficiently.

The propeller shaft is inclosed within a torsion tube, and is fitted with a universal joint at its front end. The rear axle is of floating type in which the driving shafts carry no part of the car weight. New Departure ball bearings and Hyatt roller bearings are used in the rear axle construction, the latter carrying the axle shafts and differential and the former taking the thrust. The shafts, of nickel steel, have a diameter of 1⅛ inch, while the main shaft is 1¼ inch diameter. Brakes, of conventional internal expanding and external contracting type, are 14 inches in diameter and have a width of 1⅞ inch. The braking surface is therefore ample.

The front springs are over the axle while the rears are underslung from it. These springs are 35½ and 48 inches long, respectively, and the width of all is 2 inches.

As has already been mentioned, nothing has been spared to make this light Oldsmobile a highly finished job. The cowl dash, for instance, is highly finished of Circassian walnut with compartments to right and left just as on the big car. The upholstery is of the best and equipment leaves nothing to be desired.

One slight change has been made in the body in that the back of the front seat has been made 2½ inches higher to add to comfort and appearance, the running boards are of aluminum and have mud scrapers at the doors. A refinement is the tool compartments which are concealed in the aprons at the sides. These are amply large for all paraphernalia.



Front view of the light four model 42

A rain-vision, ventilating windshield, demountable rims carrying 33 by 4 tires front and rear, clock, Stewart speedometer, one-man top, Jiffy curtains, are some of the equipment features.

The car weighs 2615 pounds with tanks filled and extra tire on rear.

The Big Six—Model 55

The biggest change in the outward appearance of the six-cylinder Oldsmobile is the sloping of the cowl to meet the hood which is also somewhat sloped. However, the body is still along the same general lines as it was, and the same is true of the bonnet and radiator.

This car has a wheelbase of 139 inches which admits of an exceedingly roomy body for seven. It is in every way highly refined and distinctive in appearance.

The chassis has been hung so as to be 2½ inches lower than it was which is advantage from the standpoint of appearance as well as stability. This has been accomplished by dropping the yokes of the front axle spindles and by making the kick-up over the rear axle higher.

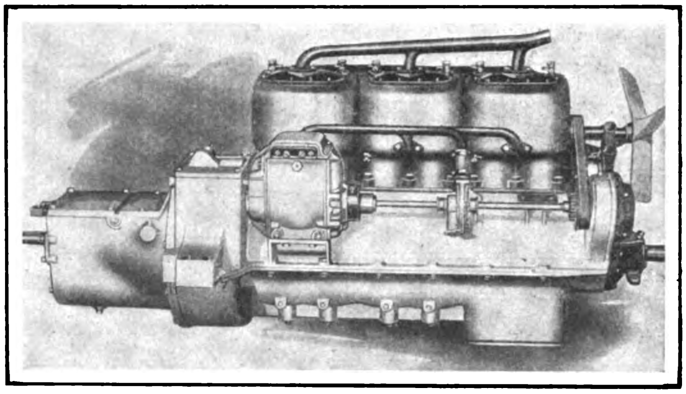
Another important change is the shifting from right to left drive, while the control has also been brought from the right to the center.

The motor is practically the same as it was except that the water jackets have been increased in size while the radiator depth has been made 4 inches instead of 3 1-2 and the cooling fan has come in for an increase of 4 inches in diameter, now being 18 inches. Thus the entire cooling system, which incorporates a centrifugal water pump, has been made more efficient.

Like a number of other cars of the year, the new Olds six has vacuum fuel feed using the Webb Jak vacuum tank which is mounted on the back of the dash. This causes the fuel to be drawn from the tank at the rear of the chassis which is still of 22 gallons capacity and has the same mounting.

A Marvel carbureter has replaced the formerly used make, while the engine-driven tire pump which is standard equipment is also of a new make—a Stewart. As an added refinement, Truffault-Hartford shock absorbers have appeared at the front.

Like the four, the motor is a Northway, although of an entirely different design, being an L-head type with cylinders cast in pairs. The valves are all on the left and intake and exhaust manifolds are separate units. The usual form of two-piece crankcase is used, it being split into two halves so that the upper half carries the crankshaft and camshaft bearings. Like all other Northways, it is a three-point sus-



Side view of the motor employed in the Oldsmobile six

pended type which has the gearbox in unit with the motor.

The bore is 4¼ inches and the stroke 5¼ inches, the piston displacement 447 cubic inches and the horsepower at 1600 revolutions is 50.

Like the four, the six uses the standard Delco ignition, lighting and cranking combination. In this case, too, there is the automatic spark advance feature, and the battery—also an Exide—is larger for its heavier work.

Unlike the four, the drive shaft of the six is not enclosed, but the torque and drive are taken by a pressed steel triangular torque arm, which parallels the shaft, and which is spring buffeted at its front end from a frame cross member. The drive shaft is of tapered section and is fitted with universals at either end. The tires are 36 by 5 inches.

Oldsmobile Power Plant Dimensions in Inches

PART	FOUR	SIX
Valve diameter	1 5-8	1 49-64

The South American Method

AMERICAN automobile manufacturers should not imagine that because the doors of Europe are temporarily closed to South America that that continent will stampede to American markets and that the people of that continent will embrace all of our systems of doing business and accept our methods of merchandising without a murmur of dissent. One maker in this country imagined that all he needed to open his South American trade was a catalog in Spanish and some pictures of his factory.

Opening trade with South America today is a bigger problem than this. It is a harder problem now than it was 4 months ago, although to many it may appear easier. Before our trade can be well developed, without the aid of Europe, we must establish our financial arrangements there. England, Germany, France and Italy have their banks well represented in the big cities in South America. America has not. We have had to do our business through London, Berlin or Paris.

The South American business man has been accustomed to do business along somewhat different lines than those followed by many American automobile companies. The buyer in Argentina has generally purchased on 90 or 120 days. The dealer there has done business as follows: The merchant in London shipping goods to Buenos Ayres, when shipping time arrives, delivers his invoices and bills of lading to his London banker and gives him at the same time a draft at 90 or 120 days for the value of the goods. These documents are forwarded by the banker to his South American branch or representative. On arrival in South America the banker notifies the local buyer that the invoices, etc., have arrived. The merchant calls on the banker, who before surrendering the shipping documents, requires him to accept the draft, to write the word "accepted" on it as well as adding his signature. At the end of the 90 or 120 days the banker collects, and failure to meet such collections is, according to the South American laws, equivalent to putting the concern in bankruptcy.

Will American business houses not have to follow the present methods of doing business in South America, for a time at least? Today many of our concerns are practically unknown to the Latin business people in South America. We should first show them that we have enough confidence to do business with them in the ways they have been doing business for years. Thus we get acquainted. Once the business is opened, opportune times will come to introduce our methods of doing business, if the present ones do not prove satisfactory.

Highways and War

HORSE-PACE in war is practically unknown in the European campaign today—in its place are motor-pace methods. The horse is little used compared with former wars, except in the cavalry and branches of the artillery service, where there are not enough motor vehicles to meet the requirements and where the needs of the hour cannot be satisfactorily met with the present type of motor vehicle. *This is the first great motor war, with motors dominating every arm of the service.*

Nothing stands out more prominently in the use of motor vehicles than the great speeds as compared with horse systems, and when you add to these the aeroplane and the wireless systems, you have a combination that has revolutionized the methods of warfare. Were it not for the wonderful roads of Belgium, France, Germany and England this general use of motor vehicles would be impossible. Instead of progress there would be stagnation; instead of moving the heavier pieces of artillery 90 to 120 miles in 24 hours, there would be miles of motor vehicles stalled in the bad roads and complete movements of army corps halted—in fact, the general scheme of activities upset. But good roads have come to the rescue, they have been as essential as reliable motor vehicles, as reliable as the new field pieces, as reliable as the other arms of the service.

The wisdom of Cæsar has again been proven, roads, good roads, are the first great essential in civilization. The great highways of Europe made the progress of those lands possible before the days of the steam trains; in America the great railroad systems have made progress possible, but America lacks one essential, good highways. The events of the present would tend to prove that even today good roads are one of the country's greatest assets.

De Dion Plant Under Military Control

Staff of Workmen Reduced from 5,000 to 1,000, All Being Paid by the Government

NEW YORK CITY, Sept. 8.—Emanuel Lascaris, manager of the DeDion Bouton selling interests in America, returned Sunday from Paris, where he has been at the DeDion factory since July 25, 5 days before war was officially declared. Mr. Lascaris says that previous to the declaration of war that 5,000 men were regularly employed in the DeDion plant but that since war started only 1,000 men have been working. At present these are engaged entirely on the manufacture of commercial vehicles.

The DeDion factory, since August 1, has been under the control of the government. All of the workmen instead of wearing overalls wear soldiers' uniforms; the workmen are paid by the war department; and General Manager Sansonnens, who is a lieutenant of artillery, has been appointed military governor of the factory, which is, in short, a huge war camp under the control of the government.

The scenes around the factory on Saturday, August 1, the day on which war was declared, were stirring in the extreme. At 4 p. m. the factory was running full force when a messenger arrived from Puteaux announcing that the mobilization orders had been signed by the government. The factory whistle was blown, all men laid down their tools, received their money and left. The majority of them were in different parts of the army service and knew exactly where they were to report. The factory doors were locked and soldiers placed in control. The soldiers in charge, however, were generally those who have been associated with the factory and are now doing their military duty by working for the government in the production of motor trucks.

On that date, August 1, the government took possession of all cars that were on hand, and the eight DeDion army trucks which were competing in the army trials were taken.

Mr. Lascaris in describing the mobilization scenes around Paris on Sunday morning, August 2, says that the work was carried out with the greatest organization and quietness. On Sunday morning there were 1,000 motor buses and trucks in the Champ de Mars, one of the public squares in Paris which was a great military camp. By Monday, all of these buses were gone, having carried their loads of soldiers to the front. In many other parts of the city similar scenes were being enacted. He thinks that there are at present upward of 80,000 passenger cars and trucks in the service of the French army. All officers use high-powered touring cars. Horses are not used except in the cavalry. The English army has gone somewhat further than the French in the use of motor cars. The English army has taken chassis and used these for hauling the artillery. A fifth-wheel device is mounted on the rear of the chassis and to this the heavy artillery carriage is attached. With this arrangement the artillery can be moved 90 to 100 miles in one day.

Only Four Tires Remain at War Scare Prices

Plenty of Crude Rubber Now in Stock in This Country, Large Shipments Having Arrived

NEW YORK CITY, Sept. 8—Tire prices in general have come down to normal conditions. Five tire companies have reduced prices to those in effect before the war started, including the Firestone, Pennsylvania, Lee, Empire and Federal. Only four companies are now selling their tires at advanced rates. These are as follows: Fisk, 15 per cent.; Goodrich and Diamond, 12½ per cent.; Republic, 12½ per cent., and the United States Rubber, 12½ per cent. It is expected, however, that one or two of these companies will reduce their prices in the near future.

A letter has been sent to the various rubber industries asking them to take up, through their respective senators and representatives, with the State Department at Washington, the matter of getting exemption for cargoes of raw material, that might be afloat in ships that left their ports before the declaration of war.

According to the Custom House, port of New York, 11,534,864 pounds of India, Balata, Gutta percha and Gutta jelutong rubber was imported during July. On July 23, the St. Louis left Southampton with a consignment of 67,000 pounds of plantation rubber for the Goodyear Tire & Rubber Co. On July 27 the *Minnewaska* left London with 95,000 pounds of plantation rubber for the same company. The B. F. Goodrich Co. has 150,000 pounds of plantation rubber on the *Chalister*, which left Singapore on July 30. It also has 150,000 pounds more of plantation rubber on the *Indrania*, which left Singapore on August 12. The Goodyear has 85,000 pounds of the same kind of rubber on the *Olympic*, which left Southampton, August 5, and also 33,500 pounds on the *New York*, which left the same place on August 10. All have arrived. The *Minnehaha* has arrived with over 600,000 pounds of crude rubber for the Goodyear company. The *Minnetonka* arrived September 7 in this port. On September 9, the Goodyear company expects to send by rail to Akron, O., thirty-five cars full of crude rubber. This is supposed to be the largest single shipment of rubber ever made from this city.

The Finance Minister of Brazil contemplates dispatching to the United States several vessels carrying rubber from Para, to bring back food and other products.

"America's Chance to Reach Its Zenith"

NEW YORK CITY, Sept. 4.—That an understanding of the characteristics of the South American people is essential before making progress in a business way in the Latin American continent is the opinion of Edward V. Douglass, secretary of the American Manufacturers' Export Association. This association, which is devoted to the fostering and promotion of the business and commercial relations between American manufacturers and foreign nations, has among its members many concerns which are either directly or indirectly interested in the automobile industry. Among its members may be mentioned the Ford Motor Co., Joseph Dixon Crucible Co., General Electric Co., Indian Refining Co., Standard Oil Co., Studebaker Corp., and the Willys Overland Co.

Speaking of South American people, Mr. Douglass said:

"Broadly speaking, there are but two classes of people throughout South America, the wealthy and the poor. There is not the enormous middle class that we find in the United States, and hence there can never be considered the large percentage of car buyers throughout these countries that we find in this country. Here there are no distinct class of people. Those of different incomes cannot be distinguished from one another.

"It is this condition in South America that gives rise to the fact that the cars that are bought are of the higher priced variety. The South American loves to make a show.

"Now is the opportunity, however, for America to step in. New York is the logical financial center of this hemisphere and since the war has shattered Europe, there seems to be no reason why there should not be a sharp increase in trade between the two continents. Every country has its period of rise and fall and this seems to be the opportunity for the United States to reach its zenith."

DETROIT, MICH., Sept. 9—S. A. Douglas has resigned from the Johns-Manville Co. and together with H. W. Kane will act as factory distributors for the following concerns: Simmons Mfg. Co., Doehler Die Casting Co., Standard Rolling Mills, Wisconsin Aluminum Foundry Co., and the Pontiac Drop Forgings Co., with sales offices in Detroit and Chicago.

Gasoline Free of War Influence, Says Standard Oil Official

Plenty of Crude Oil in Sight for at Least 2 Years with More Chance for Slight Decline Than Raise in Price

NEW YORK CITY, Sept. 8—That the international war which is tearing at the vitals of foreign countries will have no effect, either now or in the near future, upon the price of gasoline and lubricating oil is the expressed opinion of an official high in authority in the Standard Oil Co. The price of gasoline may even go down a fraction of a cent, he says, and in the next 2 years it will not increase more than 1 cent a gallon and probably not that much.

According to this official, who is in a position which gives him opportunity to survey the oil field, there is plenty of crude oil now in sight to last during at least two years, during which time it is extremely unlikely that there will be any appreciable change in existing prices.

Speaking of conditions in the oil industry, he said:

"Of course it is impossible to state positively what the next two years may bring forth, but there is nothing in sight now which leads us to think that there is any likelihood of a shortage of crude within that period, or, in fact, for a much longer period.

"The only effect the war situation can have is to decrease the demand for gasoline and lubricating oil in the foreign field. It is obvious that Europe will not employ motor cars as extensively as has been the case in the past and naturally the demand will be tremendously decreased.

"That being the case, and if the price is influenced by supply and demand, why will there not be a lower figure than at present?" was asked.

"Because the existing price is about the lowest that gasoline can be sold with a profit to the refineries," was the answer. "Take New York, for example, where an enormous amount of gasoline is used. The Standard Oil Co. receives from 9 to 11 cents a gallon from garages and private tank stations, the difference in price being due to transportation costs. Some deliveries cost us more than others. We cannot sell our product for much less and realize a living profit."

May Change Special Box Car Sizes

NEW YORK CITY, Sept. 8—As a result of the work of the Traffic Department of the National Automobile Chamber of Commerce, the American Railway Assn. has now under consideration a change in the plan for special box car dimensions that will make more convenient the shipment of motor cars.

The Railway association has been considering that special equipment should not exceed inside dimensions of 40 feet 6 inches length, 8 feet 6 inches in widtht and 9 inches in height. As the automobile industry requires 40- and 50-foot cars, 10 feet high inside for a very considerable portion of its shipments, a formal protest was sent to the Railway association and is now being considered.

The Chamber will have a representative in attendance at Chicago on September 16, when the Western Classification Committee holds a hearing on a number of matters pertaining to the classification of autombiles and parts.

No Lower Rates for Light Cars

The Chamber has been notified that the Official Classification Committee has refused the application of light car manufacturers for a lower minimum on machines of that type than applied on other automobiles.

In its conference with the Official Classification Committee, the Traffic Department has arranged that instead of enforcing the rules that bodies for freight vehicles be boxed or crated for shipment, there will be a modification so that after October 1, bodies for platform, stake or dump trucks or wagons not lettered may be shipped without being boxed or crated.

Germany Dominated 1913 Motor Trade with England

LONDON, ENG., Aug. 29.—At the present juncture it is interesting to note the extent of the trade done in motor cars, chassis, and parts between Great Britain and Germany. It will be seen from the following figures, which are taken from the last Annual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions, compiled in the Statistical Office of the Customs and Excise Department, that Germany stands to lose a much greater volume of trade than Great Britain in this particular branch of industry. The total value of the imports of cars, chassis, and parts (including tires) from Germany to Great Britain last year was £1,355,974, which was an increase of £148,819 upon the figures of the previous year, following a gradual increase since 1909. Great Britain's exports of motors, chassis, and parts to Germany, however, only amounted to £113,435 in 1913, a figure to which they had gradually grown since 1909, when they only amounted to £11,838. Great Britain's exports to Germany of foreign made cars, chassis, and parts, which are first imported into Great Britain and then re-exported, have not shown any very material expansion during the 5 years under review, as they stand now at only £39,109, against £21,315 in 1909.

The following are the details bearing out the general statements just made:

IMPORTS OF CARS, ETC., FROM GERMANY TO GREAT BRITAIN

	1909 Pounds	1910 Pounds	1911 Pounds	1912 Pounds	1913 Pounds
Complete cars	25,577	66,747	102,237	124,451	90,963
Chassis	114,421	153,900	192,508	217,973	135,998
Parts	685,497	772,041	753,235	864,731	..
*Rubber tires and tubes	..	..	..	..	929,755
Other parts	..	..	..	..	199,258
Totals	825,495	992,688	1,047,980	1,207,155	1,355,974

*Tires are now classified separately from "other parts."

It will be seen that there is a great falling off in complete cars and chassis. The increase in the value of parts imported from Germany is probably due principally to tires, the value of which for 1913 exceeded by £65,024 the total value of parts of all kinds imported during the previous year, although some portion may be owing to the use of German made magnetos.

Great Britain's export trade in motor cars, chassis, and parts with Germany is not very large. Indeed, as far as complete cars are concerned, during the past 5 years the number was apparently not sufficiently large to be separately entered in the returns. British made chassis and parts sent to Germany during the past 5 years were as follows:

EXPORTS OF BRITISH CHASSIS AND PARTS TO GERMANY

	1909 Pounds	1910 Pounds	1911 Pounds	1912 Pounds	1913 Pounds
Chassis	740	8,573	25,136	12,990	10,767
Parts	11,098	32,506	52,725	75,278	..
*Rubber tires and tubes	..	..	..	..	30,994
Other parts	..	..	..	..	71,674
Totals	11,838	41,079	77,861	88,268	113,435

*Tires are now classified separately from "other parts."

A certain number of cars and parts of foreign and Colonial manufacture imported into Great Britain are re-exported. With Germany Great Britain's trade under this head is represented by the following figures:

EXPORTS OF FOREIGN AND COLONIAL CARS, ETC., TO GERMANY

	1909 Pounds	1910 Pounds	1911 Pounds	1912 Pounds	1913 Pounds
Complete cars	6,524	7,796	13,225	17,628	13,059
Chassis	8,005	10,738	11,691	5,798	7,035
Parts	6,786	14,200	11,709	12,551	..
*Rubber tires and tubes	..	..	..	..	13,364
Other parts	..	..	..	..	5,651
Totals	21,315	32,734	36,625	35,977	39,109

*Tires are now classified separately from "other parts."

File Claims for Commandeered Cars

WASHINGTON, D. C., Sept. 4.—Americans whose automobiles were commandeered by military authorities in some of the European countries have begun filing claims with the State Department.

Most of the tourists were given receipts for their cars with the promise that they would be reimbursed.

Critchley Directs Britain's Motor Transports

LONDON, ENG., Aug. 29—J. S. Critchley, President of the Institution of Automobile Engineers, has been appointed by the War Office an inspector of mechanical transport. This position carries rank as an officer in the Army Service Corps.

Many 1915 Models at Detroit and Indianapolis State Fairs

Governor Ralston Opens Indianapolis Debut of New Season's Cars, Under Huge Tent

INDIANAPOLIS, IND., Sept. 7—Governor Samuel M. Ralston at 2 o'clock this afternoon formally opened the fall motor show of the Indianapolis Automobile Trade Assn. at the Indiana State Fair. This is the second show the association has given this year.

The show is being held in a tent at the fair ground, near the Coliseum. The tent contains 39,800 square feet of space, of which 30,000 square feet is available for exhibits. There are fifty-one exhibitors.

Special exhibitors are the Indianapolis Motor Speedway, the Hoosier Motor Club, the Howe Engine Company and Charles H. Black who is showing a gasoline car he built in 1891 and which he claims is the first successful gasoline car built in the United States.

Briscoe Touring Car Is Now $785

DETROIT, MICH., Sept. 8—*Special Telegram*—The Briscoe Motor Co. has reduced the price of its touring car from $900 to $785 while the price of the roadster remains $900. These prices are for cars fully equipped with electric starter. Thirty cars are being made now daily and production will be greatly increased from October on.

Imperial Line to Be 1 Four, 2 Sixes

DETROIT, MICH., Sept. 8—Three models instead of four will constitute the Imperial line for 1915. In place of two fours and two sixes, there will be one four and two sixes. One of the latter is an introduction to the Imperial line, being a light six model.

The model 64 four-cylinder car in both roadster and touring car bodies, sells for $1,085 for the 1915 season in place of $1,500 last year. This car has a 3.75 by 5 inch motor fitted with a Stromberg carbureter, Gray & Davis starting and lighting system and battery ignition. The wheelbase is 115 inches and the tires 32 by 3.5 all around. This car is equipped with left drive and center control.

The model 56 six-cylinder is a larger edition of the four cylinder model, having the same size cylinders as the four. It is fitted with a Splitdorf magneto, Stromberg carbureter and a North East starting and lighting system. The wheelbase is 130 inches and the tires are 36 by 4.

The Imperial light six will be shown for the first time at the Chicago show. It will cost $1,535 for a seven-passenger body. It will be fitted with a Continental block engine of 3¾ inch bore and 5 inch stroke. It will have the Gray & Davis starting and lighting, Stromberg carbureter, wood wheels and 34 by 4 inch tires.

New Paterson Four on View in Detroit

DETROIT, MICH., Sept. 8.—A new Paterson four-cylinder car is being shown in Detroit. Its price is $1,085 instead of $1,200 as asked for the 1914 model. It has Northway block motor, of 3.5 bore by 5-inch stroke, Delco starter and lighting system, Schebler carbureter, 112-inch wheelbase and 33 by 4-inch tires. The axles are Weston-Mott, semifloating. The standard color will be blue and the bodies of streamline design. There will also be a new six-cylinder but this is not ready for announcement at the present time.

$860 for Chevrolet Roadster, Complete

FLINT, MICH., Sept. 8—The 1915 Chevrolet line consists of the Baby Grand model, four-cylinder touring car selling at $985 with electric starter and lighting system and the Royal Mail roadster selling at $860 with full electric equipment.

Both cars have the four-cylinder block Mason motor having a bore of 3 11/16 inches and a stroke of 4 inches. The Zenith carbureter will be fitted as standard equipment. On the cars that are specified to have an electric lighting and starting system, the Auto-Lite company's product is employed. Where electric lighting and starting is not used, the price is $875 for the Baby Grand model and $750 for the Royal Mail. In this case the Simms magneto is standard equipment.

The wheelbase remains at 106 inches and the tires are 32 by 3.5 all around. The wheels are wood. Left steering with center control is also continued. The axles are the Walker-Weis semi-floating type and the color is gun metal on the regular stock cars.

Price Cuts in 1915 Abbott-Detroits

DETROIT, MICH., Sept. 8—Abbott-Detroit 1915 cars will be much the same as the 1914 models except that there will be a cut in price and new streamline designs of bodies. The six-cylinder roadster model G will sell for $100 less than it did in the 1914 model, being now $2,190. The six-cylinder seven-passenger model F remains at $2,290 and the four-cylinder seven-passenger model L at $2,885. The four-cylinder five-passenger model K will sell for $1,785.

Six 1915 Detroit Electrics Announced

DETROIT, MICH., Sept. 8—The complete 1915 line of the Anderson Electric Co., makers of the Detroit electric, consists of a cabriolet roadster selling at $2,650, a rear-drive brougham selling at $2,850, duplex-drive, $3,000, forward-drive, $2,950, large rear-drive brougham, $2,950, small rear-drive brougham with bevel gear, $2,600. Wire wheels are optional.

Gasoline Tax To Yield $20,000,000 Yearly

WASHINGTON, D. C., Sept. 9—The first draft of the emergency revenue bill, which is to be passed in accordance with the recommendation of President Wilson, was completed today by the Democratic members of the Committee on Ways and Means.

One of the essential details of the bill, which will be submitted to the House the latter part of this or early next week, is the tax on gasoline of $0.02 per gallon, which it is claimed will yield about $20,000,000 a year.

Clayton Bill Passed—Hits Patent Monopoly

WASHINGTON, D. C., Sept. 3—The Clayton bill, the second and last of the administration trust measures to be considered at this session, passed the Senate by a vote of 46 to 16. The Senate struck from the House bill sections, 2, 3 and 4 relating to unfair trade practices, and substituted section 4, known as the Walsh amendment, intended to prevent the patent monopoly, which the Supreme Court is supposed to have recognized by its decision in what is known as the Dick mimeograph case.

Columbus Dealers Wroth at Fair Conditions

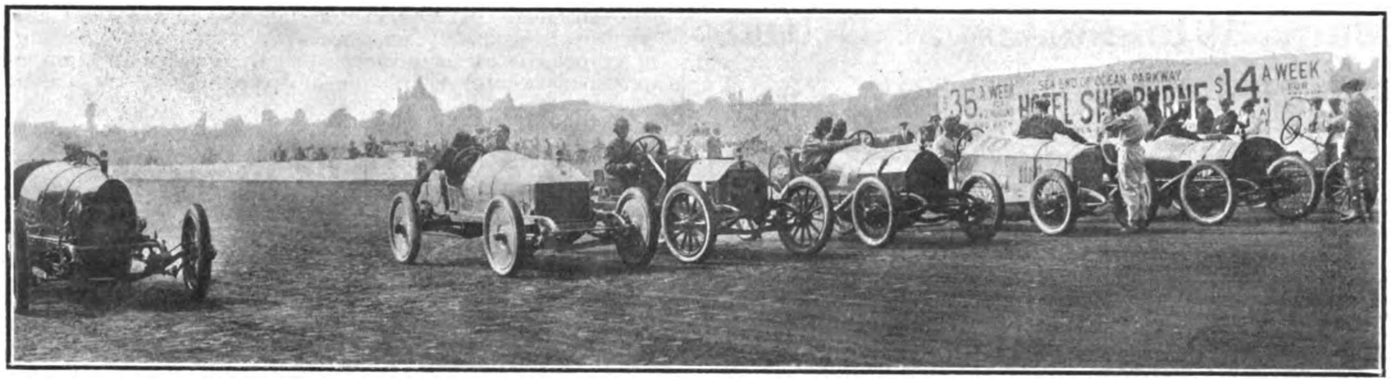
COLUMBUS, OHIO, Sept. 7.—The Columbus Auto Trades Assn., an organization composed of agents in central Ohio territory, has adopted resolutions in the form of an ultimatum to the board of managers of the Ohio State Fair. The ultimatum protests against the charging of an admission of 50 cents for each and every one connected with the automobile exhibits, without pass out checks and also against the location of the automobile displays. It is claimed that many of the displays were placed near stone crushers and thereby ruined by the dust. The roofs of buildings leaked and damaged cars on exhibition also. It was agreed that no displays of automobiles be made by Columbus dealers at the next state fair unless the conditions were remedied.

Hup Dealers Convene in Minneapolis

MINNEAPOLIS, MINN., Sept. 7—The Hupmobile dealers' convention in Minneapolis Sept. 8-9-10, with entertainment features by the R. W. Munzer & Sons Company, was attended by factory officials who drove up in a 1915 five-passenger car. They were President J. Walter Harris, Commercial Manager F. A. Harris, General Sales Manager F. J. Mooney, and Factory Superintendent S. H. Humphreys. A dinner was given Thursday night at which W. E. Lee, one of the candidates for governor in Minnesota, and Mayor W. G. Nye spoke.

Mercer Discontinues Racing Temporarily

TRENTON, N. J., Sept. 7—Following the unfortunate accident in the Elgin road race August 22, when Spencer E. Wishart was killed, and his mechanic, John C. Jenter, later died from injuries, the Mercer Automobile Co. has decided to discontinue racing for the remainder of this year at any rate.



Line-up of cars preparing to start in 50-mile event on Saturday. DePalma in No. 10 won this race

De Palma Draws 15,000 to Brighton

NEW YORK CITY, Sept. 8—Ralph De Palma, piloting a Mercedes, was the bright particular star at the 2-day race meet staged by the Motor Dealers' Contest Assn. at the Brighton Beach seaside track, Saturday and Monday, September 5 and 7.

With only two exceptions, De Palma won every event in which he started, the only races which he lost being the two free-for-all handicaps in which he was unable to overcome the advantage of those who were pitted against him. Not only did he win the 100-mile Labor Day Sweepstakes, which was the feature event on Monday, forcing his Mercedes 100 times around the mile circuit in 1:40:15, but he won the 50-mile "warming up" trip which was run off on Saturday and was the feature event of that day. In this race his time was 50:42 2-5. In several of the races better time was made than ever before on the old Brighton Beach track.

During the 2 days of racing there was one unfortunate incident. When Frank Dearborn was driving his Peugeot in second place in the 50-mile feature event on Saturday the right front tire blew out, precipitating the car, after a long skid, through the outer fence on the grandstand turn. Later it developed that Dearborn had sustained a fractured skull and internal injuries, and that Harold McCarthy, his mechanician, was quite seriously injured internally.

At the hospital it is reported on Wednesday morning that Dearborn died at about midnight; he had remained unconscious since the accident. McCarthy, however, who was less seriously injured, a splinter of one of his ribs having punctured his lungs, has greatly improved and quite likely will recover.

At the time of the accident Dearborn was in his 41st mile and was racing to make up time which he had lost because of a stop for tires. Throughout the race, up to this point, it had been a see-saw affair between De Palma, Dearborn and Le Cain. De Palma won, his time being 50:42 1-5.

Of the other events on the program on Saturday the 10-mile class C race, which was won by De Palma in 10:20 3-5, proved the most exciting. For 9½ miles De Palma and Morton, in a Mercer, raced practically wheel to wheel; only at the finish line did De Palma forge ahead, winning by inches. Otherwise there was practically no competition, the winner in each case running away from his field. In the 25-mile free-for-all De Palma bettered his own time of 24:35, made last year with a Mercer, by covering the distance in 24:08 2-5.

Reversing his previous practice of driving only fast enough to beat out his nearest competitor, De Palma early assumed the lead in the 100-mile Labor Day Sweepstakes, and at the finish had opened a gap of 5 miles between himself and Bergdoll in his Erwin. The absence of Dearborn and his Peugeot robbed the contest of much of its interest, for next to De Palma's Mercedes the Peugeot was undoubtedly the fastest car on the track. The summary:

Saturday, September 5

CAR	DRIVER	TIME
10 Miles, Class C, 161-300 Cu. In.		
Mercedes	DePalma	10:20 3-5
Mercer	Morton	
Chevrolet	LeCain	
10 Miles, Class C, 301-600 Cu. In.		
Peugeot	McCarthy	10:34 4-5
Stutz	Morgan	
25 Miles, Class E, Free-for-all.		
Mercedes	DePalma	24:08 2-5
Chevrolet	Jessop	
Erwin	Bergdoll	
10 Miles, Class D, Free-for-all Handicap		
Peugeot	Dearborn (10s)	9:02 4-5
Chevrolet	Le Cain (40s)	
Mercedes	DePalma (scratch)	
50 Miles, Class E, Free-for-all		
Mercedes	DePalma	50:42 2-5
Chevrolet	LeCain	
Marquette	Galvin	
Chevrolet	Jessop	

Monday, September 7

CAR	DRIVER	TIME
10 Miles, Class C, 161-300 Cu. In.		
Mercedes	DePalma	10:00 4-5

Chevrolet	LeCain (40s)	10:14 1-5
Mercedes	DePalma (scratch)	
Mercer	Morton (20s)	
100 Miles Labor Day Sweepstakes		
Mercedes	DePalma	1:40:15
Erwin	Bergdoll	
Chevrolet	Jessop	

Disbrow Fast at Michigan Fair—Show Also

DETROIT, MICH., Sept. 8—The 2 days' race meet at the Michigan State Fair held September 6 and 7 was probably the best attended ever held in Detroit, 10,000 people being present both days. Louis Disbrow, driving the Simplex Zip, was the big winner of the meet, taking six firsts. His car made the fastest time, covering 1 mile in 50 and 2/5 seconds. His time of 9 minutes 16 2/5 seconds in the 10-mile race is claimed fastest ever made in open competition on circular track.

Bob Burman was forced out on the first day owing to a broken piston rod on his Peugeot and again on Monday. The finish in the 10-mile race Monday ended in a dead heat between Hearne in a Case and Raimey, also in a Case, in 9 minutes 42 seconds.

At the motor car exhibition at the State Fair, local agents or branches are showing the 1915 Maxwell, Overland, Regal, Mitchell, Krit, Studebaker, Buick, Hupmobile, Jackson, Premier, Oldsmobile, Grant, Detroiter, Haynes, Oakland, Peterson, Imperial, Chevrolet, Hudson, Ford, Cartercar, Reo, Detroit electric. Among the commercial vehicles exhibited are the Federal, Commerce, Standard and Kelly-Springfield.

Races Save Iowa Fair from Deficit

DES MOINES, IA., Sept. 7—A day of automobile races saved the Iowa State Fair this year from what promised to be a financial deficit and from showing a heavy loss in attendance. The final day of the exposition was given over to the races in which several drivers of note participated and the crowd

Starter Wagner flagging Peugeot winning 10-mile race at Brighton attracted for the automobile events saved the day for the state fair. The receipts of the final day were enough for the fair to show a profit of over $20,000 and to cut the loss in attendance as compared with last year to only 8,000.

Nearly 25,000 people attended the races. The big feature was the final free-for-all in which Louis Disbrow drove his Simplex Zip across the tape with its nose projecting by inches only beyond that of Johnny Raimey's Case. Another feature was a race between Eddie Rickenbacher, winner of the Sioux City race, and Lincoln Beachey, the aviator. Beachey negotiated the half mile track four times while Rickenbacher went around thrice. Disbrow was a winner from the start. In the 1-mile test he made the two laps in 1:09 1/5 and Raimey was second in 1:10 1/5 while Rickenbacher was third in 1:10 3/5. O'Donnell's Duesenberg was first in the 3-mile event in 3:45 3/5. Disbrow cut the mile record of 1:08 4/5 to 1:08 3/5.

Home Talent in Washington Fair Races

TACOMA, WASH, Sept. 1.—Automobile races under the auspices of the Northwest Automobile Assn. were the feature August 30 at the Southwest Washington Fair at Centralia.

Jim Parsons, the favorite Northwest driver in the Romano Special, won four out of the five races on the program, in spite of having his car go through the fence prior to the start of the day's races.

The first race was for a mile against time from a flying start. Parsons won in 1:10 1-2; Joe Krause second, Velie, 1:15 1-2; Fred Hess, Ford, 1:17 1-2; C. Latta, Lozier, 1:18 1-2; Ray Lentz, Farco, 1:19, and Earl Staley, Studebaker, 1:24 1-2.

The second race was won by Staley in a Studebaker. The third race was for five miles between the three fastest cars in the first race and was won by Parsons in 6:36. The Velie's time was 6:37 and the Ford's 6:44 1-2.

The fourth race, a 10 mile free-for-all, was all Parsons' again, won in 13:14. The last event, an Australian pursuit race, was won by Parsons in less than three miles by passing the Ford and Velie in order. Over 3,000 was the attendance. Track was in good condition. Races were under the personal direction of Robert A. Hiller and were a success.

Entries Open in Los Angeles-Phoenix Race

LOS ANGELES, CAL., Sept. 2.—The first entry for the Los Angeles-Phoenix-San Diego Exposition road race is that made by Don Lee, who entered a Cadillac, to be driven probably by Harry Ham. A second Cadillac will probably be entered by Louis Nikrent.

The classification of the race is given as class E, free-for-all. The entry fee is $200 up to October 8 and $300 after that day up to October 22.

The size of the purses will depend entirely upon the number of entries. For instance, if there are 40 cars entered the six purses will be $3,500, $2,250, $1,750, $1,250, $1,000 and $500. If there are 30 entries the purses will be $3,000, $2,000, $1,750, $750, $500 and $250. If there are 25 entries the five first to finish will receive respectively $3,000, $2,000, $1,500, $500 and $250. If there are only 20 entries there will be only four purses, of $2,500, $2,000, $1,500 and $500. Should there be 10 entries only then first prize will consist of $2,500, second $1,500 and third $500.

The course will be practically the same as last year except between this city and San Diego, as Riverside is to be placed upon the route this year.

Four Perfect in Light Car Run

NEWARK, N. J., Sept. 8—Four cars out of nineteen contestants, who started from this city on September 5 on the 300-mile reliability light car run of the Cyclecar Club of N. J., to Atlantic City and return, returned last night with perfect scores.

The four cars were the sole survivors of the run. For the last 2 days the tour was a battle royal between G. A. McLaren, of this city, driving a Twombly, and C. A. Coey, of Chicago, driving a car of his own manufacture. Not only did McLaren and Coey finish in the same time which they had at Atlantic City the day before, but two other Jerseyites, Harry Seward, of Rutherford, and E. W. H. Riepel, of Ridgewood, in a Zip, also secured a perfect score.

Most of the competing cars averaged 35 miles to the gallon of gasoline, while Coey went through the trip without a puncture.

Elmer Thompson to Direct Parade

NEW YORK CITY, Sept. 5.—It was decided to proceed with plans for a great motor car pageant at a luncheon of the New York Commercial Tercentenary Commission yesterday. The luncheon was in the rooms of the Automobile Club of America.

Elmer Thompson, secretary of the automobile club, was unanimously chosen chairman of the automobile auxiliary committee.

According to tentative plans which have been adopted there will be a mammoth motor car parade, which, it is proposed, will be divided into four sections, industrial, floral, grotesque and electrical. In each division there will be separate prizes for the winners selected by the judges. In addition there will be a grand prize. This probably will be a large gold medal.

The parade is to take place during the evening of Wednesday, October 24, and it was announced that already the Colgate company and the makers of the Thermos bottles have entered floats. An appropriation of $10,000 has been made for the purpose of illuminating the line of march.

More than 40 guests were present, among them:

Alfred Reeves, National Automobile Chamber of Commerce; A. G. Batchelder, American Automobile Association; Fred Wagner, Vice-President George F. Kuntz, Tercentenary Commission; William C. Poertner, Poertner Motor Car Co.; George H. Duck, Motor Truck Club of America; Elmer Thompson, Secretary Automobile Club of America; Secretary De Forest, of the Harlem Board of Trade; Secretary E. H. Hall, Tercentenary Commission; Harvey Robinson, Electric Vehicle Association of America; M. L. Downs.

Eight Cars Start in Wisconsin Tour

MILWAUKEE, WIS., Sept. 7—*Special Telegram*—Eight cars are contesting in the fourth annual Wisconsin Trade Tour which started from Milwaukee this morning and which reached Green Bay, Wis., tonight with every car showing a perfect score.

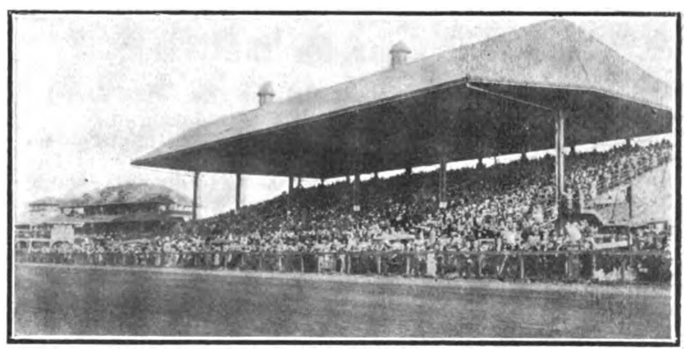
In the dealers' division are Buick, Jeffery, Franklin, new R. C. H., Studebaker and Chevrolet, while in the private owners' division are J. B. Babcock, Franklin and O. H. Stenzel, while the run for the last 3 days covered 483 miles.

The tour is under grade one rule with special regulations framed to cover the stock car angle; both reliability and fuel economy figure in the rules.

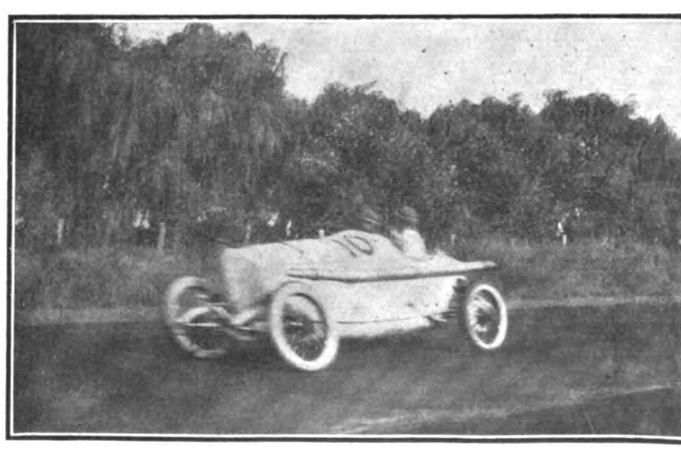
"Keep Money in Circulation"—Mitchell Branch

MILWAUKEE, WIS., Sept. 7—The Milwaukee branch of the Mitchell Automobile Co., 528-532 Broadway, has just issued a letter to its customers which reads:

"The business conditions of today and for the immediate future are largely what you and I choose to make them.



Crowd in grandstand on Labor Day at Brighton races



De Palma speeding on the back stretch in Brighton races

Each one of us can help boom things by forgetting the hole in the doughnut and forging ahead as though nothing unusual was happening on the other side of the pond.

"We have reason to be optimistic. The Mitchell factory in Racine was never before so busy at this season of the year. Why shouldn't this be the case, with good crops all over the country for which growers are receiving the highest prices in history?"

Maxwell Plant Entertains 100 Dealers

INDIANAPOLIS, IND., Sept. 8—About 100 Maxwell dealers attended a meeting in Indianapolis September 1 and were the guests of R. L. Malkin and G. H. Williamson, district salesmen for the Maxwell Motor Sales Corp. for Indiana and eastern Illinois. There was an exhibition of motion pictures, showing the manufacture of the Maxwell 25, a luncheon and a number of interesting talks.

Bonnell To Handle Dodge in Newark

NEWARK, N. J., Sept. 9—The Bonnell Motor Car Co., this city, has been incorporated with a capital of $100,000, to handle the Dodge car in this territory. The incorporators are Horace A. Bonnell, Jacob W. Mason and A. M. Bonnell. A salesroom will be opened at 273-275 Halsey street.

Houpt Handles Mitchell in Five States

NEW YORK CITY, Sept. 8—Harry S. Houpt has taken on the Mitchell line for New York State, New Jersey, Pennsylvania, Delaware and Maryland, embodying a population of over 15,000,000.

He will also continue to handle the Lozier. He has at present agencies in this city, Brooklyn and Philadelphia. He will establish new dealers in those communities where the Mitchell is not represented.

William Wield has been appointed wholesale manager. A stock of $160,000 in repair parts is being carried.

Chalmers' Earnings for Fiscal Year, $1,121,929

NEW YORK CITY, Sept. 4—The Chalmers Motor Co.'s balance sheets as of June 30, 1914, shows its assets as follows: Cash, $1,039,491; notes and accounts receivable, less reserve, $939,703; merchandise inventories, less reserve, $3,473,162; prepaid expenses, $23,759; stock of other companies, $527,599; sales branches, $30,961; plant and equipment, $2,113,278; good will, $1; total, $8,147,958.

Liabilities—Current merchandise accounts, $560,860; deposits, dealers' contracts, $93,408; accrued accounts, $32,278; reserves, $200,881, preferred stock, $1,319,300; common stock, $5,000,000; surplus, $941,229; total, $8,147,958.

According to these figures, $180,700 of the preferred stock has been retired, or $5,700 more than is required per year.

Adding this retired preferred stock to the surplus, $941,229, the company would have earned $1,121,929.

Extra 2 Per Cent. Firestone Dividend

AKRON, O., Sept. 4—The Firestone Tire & Rubber Co. has declared a quarterly dividend of 3 per cent. and an extra dividend of 2 per cent. on the common stock; also a regular quarterly dividend of 1¾ per cent. on the preferred stock. All the dividends are payable October 15 to stock of record of October 1. The previous declaration on the common stock was 2½ per cent.

The common dividend represents an advance in the rate from 10 per cent. to 12 per cent. per annum. The extra dividend has not been declared heretofore.

The gross sales of the company, in the fiscal year ended July 31, 1914, exceeded $19,000,000 against $16,600,000 in the previous year, $11,500,000 in the fiscal year 1912, $7,500,000 in the 1911 year and $5,000,000 in the year ended July 31, 1910.

The company has $3,000,000 common and $1,000,000 preferred stock outstanding, so that earnings, which amount to approximately $3,000,000, are at the rate of nearly 100 per cent. on the common after the 7 per cent. cumulative dividends on the preferred stock.

Market Reports for the Week

This week's markets saw the usual changes. Tin dropped $2.75 per 100 pounds, the arrival of a large amount of that product at the Atlantic ports, having a depressing effect with a small demand from domestic consumers for spot and nearby positions. Copper underwent no material change last week. The demand for this product was light. It was reported that 3,520 tons of copper was exported from Atlantic ports for Europe. In the rubber market consumers are holding aloof from the market pending developments. It is reported that no further auctions will be held in London until after the close of the war.

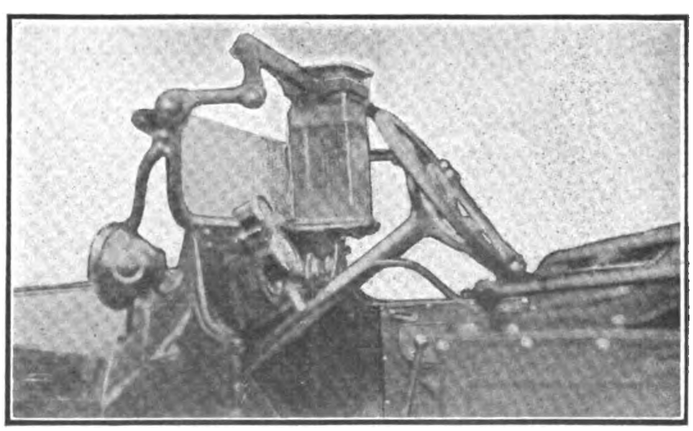
1 Gallon Drives Chevrolet Roadster 27.9 Miles

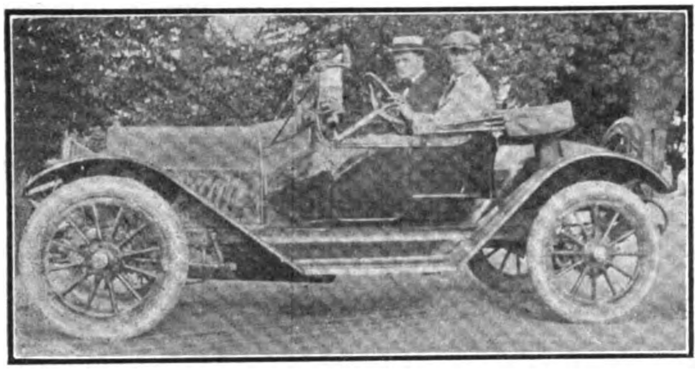
NEW YORK CITY, Sept. 3—A Royal Mail model Chevrolet roadster under test over the roads of Central Park in this city ran 27.9 miles on a measured gallon of gasoline. The car tested was a standard stock model taken from the Broadway sales room and fitted with regular equipment except that the generator was disconnected at the time of the test and the carbureter fitted a one inch Stromberg model-K with a 64 needle. A hot air attachment was fitted.

The test was observed by J. E. Schipper of THE AUTOMOBILE and was carried out under strictly touring conditions. The average speed maintained was 21.6 miles per hour. The brakes were used frequently owing to traffic conditions along the course which was all in Central Park, traveling north on the west drive, and south on the east drive. The carbureter was adjusted for service conditions and did not have the gasoline cut down any more than would be done on the average car. In fact on the same adjustment the car climbed the Abbey hill on direct drive at a minimum speed of 16 miles per hour. This is a gradient which averages approximately 8 per cent.

During the test, the car was declutched on the steeper hills allowing it to coast with the motor idling, and the interconnection which is generally used between the clutch and brake operating on the same pedal, was removed for coast-



Method of mounting graduated tank on Chevrolet test car



Fred Tucker, Stromberg company, left, and Paul Dean, Chevrolet company, driving Royal Mail Chevrolet used in economy test

ing freedom. The clutch slipped slightly when the car was quickly accelerated. The weight of the car complete with two passengers, was 2585 pounds. The tires were Goodyear, 30 by 3.5 Allweather, non-skid tread all around with the rear tires inflated to 70 pounds and the front to 60 pounds. Gasoline was .71 Beaume at 60 degrees Fahrenheit. The odometer was a Stewart-Warner, checked by measurement around the circumference of the wheel. The gear ratio on direct was 4 to 1.

The Chevrolet, Model H-2, 4-cylinder engine used on the Royal Mail roadster, has its valves in the head. It has a bore of 3 11/16 inches and a stroke of 4 inches. In this instance the car was operated with the windshield in one-half position and the certified gallon measure was carried on a bracket on the top of the windshield. One gallon of fuel was placed in this, and after the gasoline in the connecting tube had been exhausted the car was run until it stopped through lack of fuel.

July Exports from New York Decrease $249,915

NEW YORK CITY, Sept. 5.—Exports of automobiles, commercial vehicles and their parts from the port of New York during the month of July amounted to $947,147, against $1,197,062 for July, 1913, a drop of $249,915.

The imports for July, 1914, amounted to $116,837, as compared with $82,133 for that month in 1913, a gain of $34,704.

June exports were a little higher than those of July, amounting to $1,399,125, or a gain of $451,978. The imports during that month amounted to $108,579, or $26,446 lower than July.

The total figures for the month of August have not been completed as yet. The following figures will give the number of cars and commercial vehicles exported and imported during June and July of 1913 and 1914:

JULY EXPORTS

	1914 No.	1914 Value	1913 No.	1913 Value
Cars	840	$638,452	1,183	$1,037,680
Trucks	32	72,102	12	18,344
Parts	..	236,593	..	141,038
Total		$947,147		$1,197,062

JULY IMPORTS

	1914 No.	1914 Value	1913 No.	1913 Value
Cars	9	$17,384	30	$71,543
Parts	..	99,453	..	10,590
Total		$116,837		$83,133

Bakelite Commutator Breaks at 9,060 Revolutions

AN interesting test on the new Bakelite commutator recently adopted by the United States Light & Heating Co. of Niagara Falls, N. Y., has just been completed in the laboratories of this concern. The method by which the test was made was one which served to show a comparative value of the Bakelite moulded insulation as compared with those used previously.

Stress Equal to 15,230 Pounds

The commutator with the improved type of insulation was speeded up to 9,060 revolutions per minute, or 24,600 feet per minute peripheral speed before going to pieces. The chief engineer of this department of the U. S. L. company states that the disrupting forces at this speed figured out to 15,230 pounds at which point the commutator failed by centrifugal strains. As the maximum speed at which such a commutator would be operated in service is only 3,500 revolutions per minute, the factor of safety in the above instance would be 6.7 since the centrifugal force tending to break the commutator varies as the square of the speed.

Made to Stand 10,000 R.P.M.

It is interesting to compare this test with previous ones made by this company on commutators made up of brass and steel rings with mica between the rings and bars. While these constructions prove to be strong enough in practice, the brass commutator went to pieces at 6,000 revolutions per minute, while the steel commutator would stand only approximately 8,000.

Minor alterations made in the design of the new Bakelite commutator have resulted in an increase of strength so that the engineers of the U. S. L. company are of the opinion that these commutators will not stand the stresses imposed upon them at 10,000 revolutions per minute.

The commutator tested is shown in the accompanying illustrations. A part sectional view is given in Fig. 1, showing the construction of the copper segments with the steel rings and the Bakelite insulations. This type of commutator when complete weighs 8.6 pounds and has an outside diameter over the forks of 13.375 inches. When tested the forks were removed, leaving a net weight of 7.06 pounds and an outside diameter of 10.375 inches. This is the diameter at the commutator face.

Tested Under Service Conditions

In order that the commutator while being tested would approach service conditions at the temperature, it was heated to 265 degrees Fahrenheit before testing. This temperature is many degrees more than would occur in practice. In working out the calculations showing that the disrupting force amounted, as stated, to 15,230 pounds, or about 7 tons per square inch, it was shown that since this was resisted by the tensile strength of the steel rings and the Bakelite, the holding power of these components of the commutator is evidently equal to this figure.

It is stated that in addition to having the high tensile strength for commutator insulation, that Bakelite possesses the important qualification of having a high dielectric strength. That is, it resists electricity to a high degree. It will not soften under heat up to at least 400 degrees Fahrenheit and is impervious to oil and moisture.

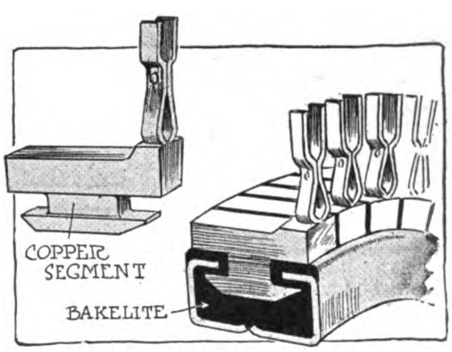


Fig. 1—Section through the Bakelite commutator adopted by the U. S. Light and Heating Co.

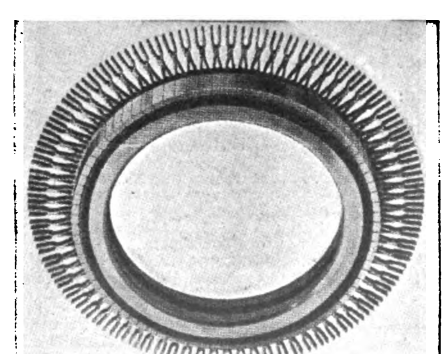

Fig. 2—Assembled view of the complete comutator recently tested up to a speed of 9,000 revolutions per minute

Factory Miscellany

Gear Co. Working Overtime.—The New Process Gear Corp., Syracuse, N. Y., reports that it is working overtime to keep up with a volume of business larger than any heretofore handled. An additional building is now being erected, and the capacity of the case-hardening and heat-treating departments are again being doubled. The total production of the plan in spur, spiral and bevel metal gears and New Process noiseless gears and pinions will, after January 1, 1915, be in excess of 1,000,000 per year. A large part of this output is already contracted for.

Wants Factory Equipment—J. A. Hill, Essex, Ont., is ready to purchase the equipment for a factory to manufacture cycle cars.

Covert to Erect—Covert Motor Vehicle Co., Lockport, N. Y., will erect a $50,000 addition as soon as switching facilities can be adjusted.

Canadian Top Will Enlarge—The Canadian Top Co., Tilbury, Ont., manufacturer of automobile tops, contemplates enlarging its present plant.

McQuay-Norris Moves—The McQuay-Norris Mfg. Co., St. Louis, Mo., manufacturers of leakproof piston rings, has removed into its new quarters, 2208 Locust street.

Tire Plant in New Orleans—The York Co-operative Tire & Rubber Co., New Orleans, La., plans to erect a tire manufacturing plant. Leslie Dunnis is president and W. Cooke, vice-president.

Radiator Plant for Jamestown—Jamestown, N. Y., men, headed by John Gabrielson, have chartered the Gabrielson Car Parts Manufacturing Co., with $35,000 capital, and will build a plant at Jamestown to manufacture automobile radiators.

Splitdorf Ready for All Orders—The Splitdorf Electrical Co., Newark, N. J., states that it is ready to fill all orders for ignition units. All the units of its output are made in America and it has sufficient raw material on hand to effect all deliveries.

Avon Tire Co. Increasing—The Avon Tire Co., Lynn, Mass., has secured the buildings formerly used by the Sagamore Rubber Co., East Saugus, and has moved into them, increasing its force to more than 200, which is turning out solid tires that have a good sale.

Lambert Co.'s New Plant—The Lambert Mfg. Co., Anderson, Ind., has acquired a 6-acre site at El Segundo, Cal., and will erect a plant for the manufacture of motor tractors. The plant will be 60 by 200 feet. S. J. Smith is manager and J. W. Lambert, president.

Auto Products May Move—The Board of Trade has succeeded in negotiations whereby the Auto Products Co., Canton, O., will remove to Canal Dover, O., as soon as $20,000 worth of 7 per cent. preferred stock can be sold. It is planned to begin operations within 60 days as soon as negotiations are completed.

Want Plant in Neenah—The Neenah (Wis.) Advancement Assn. is in negotiation with the Rayfield Cyclecar Co., Christman, Ill., with a view to inducing the removal of the plant to Neenah. The Rayfield people are asking that Neenah capital subscribe to $20,000 worth of its stock.

Cooking Outfits for Automobiles—A factory for the production of cooking outfits designed especially for motorists is being established in the former Reliance Engine Co.'s foundry at Racine, Wis., by John Dean and G. M. Prentiss, who have secured ample financial backing to organize a $50,000 corporation for this purpose.

Rhineland's French Factory Running—The Societe Francaise des Roulements a Billes, Ivry Port, Paris, France, the foreign plant of the Rhineland Machine Works Co., New Britain, Conn., is running. The American factory, the Fafnir Bearing Co., New Britain, is running full force, and has a supply of imported steel and balls to last for many months.

Dayton Cyclecar Plant in Joliet—The Dayton Cyclecar Co. of Ohio has concluded negotiations for the opening of a branch factory in Joliet, Ill. It is planned to construct 3,000 of these cars during the coming year. Thomas Donovan, representing the Dayton company, has been in Joliet for several davs conferring with the Chamber of Commerce regarding suitable quarters.

Standard Welding's Big Rim Contracts—Rim contracts secured so far this season by the Standard Welding Co., Cleveland, O., indicate that more than 150,000 automobiles of the 1915 stamp will have Stanweld detachable or demountable rim equipment. And this quantity does not include the plain clincher type rims, of which the Standard company manufactures approximately one and a half million a year.

Maxwell's Memphis Branch Plant—The Maxwell Motor Co., Detroit, plans to establish a branch plant at Memphis, Tenn. It will be used for manufacturing light parts and for assembling work. A considerable amount of machinery will be needed. The building will be six stories, and with its equipment will cost $200,000. A site has already been leased. Vice-president Charles Gould is in charge of locating the branch, which will serve the Southern and Southwestern trade.

The Automobile Calendar

Sept. 7-14	Hartford, Conn., Show, Charter Oak Park.

Feb. 22	San Francisco, Cal., Vanderbilt Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

The Week in  the Industry

Motor Men in New Roles

MORGAN FORD'S Newark Booster—Gaston Plaintiff, the New York City manager for the Ford Motor Co., has arranged with W. J. Morgan to become connected with the Newark, N. J., branch as a sort of general booster, his principal work being in the sales department and also in local publicity.

Eib Frisco Oakland Manager—C. C. Eib will hereafter control the sales of the Oakland car in San Francisco.

Johnston Sales Manager—J. E. Johnston has been named sales manager for the Hennepin Truck Sales Garage, Minneapolis, Minn.

Haskins Branch Manager—C. B. Haskins has been appointed branch manager of the Walker-Bin Co., 239 Michigan avenue, Detroit, Mich.

Landman Sales Manager—A. E. Landman has been appointed sales manager for the Don Lee Co. in Los Angeles, distributor of Cadillac cars.

Dowse with Kelly-Springfield Tire—R. P. Dowse, who was general sales representative of the Goodyear Tire & Rubber Co., Detroit, Mich., is now with the Kelly-Springfield Tire Co., Akron, O.

Lay Joins Dodge Bros.—R. P. Lay, assistant chief engineer of the H. H. Franklin Mfg. Co., Syracuse, N. Y., has resigned his position and September 1 took up his duties with Dodge Bros., Detroit, Mich.

Clough Resigns—C. Roy Clough has resigned as manager of the Brasher Motor Car Co., Columbus, O., to accept a position as sales manager with the Broad-Oak Automobile Co., also of Columbus.

Stewart Abbott Sales Manager—C. D. Stewart has been appointed sales manager of the Abbott Motor Co., Detroit, Mich. He was formerly the Abbott company's branch manager in Harrisburg, Pa.

Moore Resigns from J.-M.—F. L. Moore has resigned as city sales manager for the Indianapolis sales branch of the H. W. Johns-Manville Co., to take a similar position in that city with the Lyons-Atlas Co.

Myers Connects with Cole—W. D. Myers has become associated with the sales department of the Cole Motor Car Co., Indianapolis, Ind. Until recently Mr. Myers was general sales manager for the Stutz Motor Car Co.

Earle Lozier Wholesale Representative—R. D. Earle, who formerly was head of the American Automobile Co., Philadelphia, Pa., has become associated with Harry S. Houpt, Inc., 250 North Broad street, the local Lozier agency, in the role of wholesale representative.

Everitt Hayes Body Manager — The Hayes Mfg. Co., Detroit, Mich., announces that B. F. Everitt has been appointed manager of its body building department. Mr. Everitt is well known in the automobile trade having been connected with the E-M-F, Wayne and Everitt automobile companies.

Packwood Briggs-Detroiter Sales Manager—F. B. Packwood, formerly in business in Lincoln, Neb., where he was distributor for the E-M-F, Everitt, Krit and Winton cars, has been appointed western sales manager of the Briggs-Detroiter Co., Detroit, Mich., with headquarters in Lincoln.

Williams Resigns from Franklin.—W. M. Williams, who for the past 2 years has been advertising manager of the Franklin Automobile Co., Syracuse, N. Y., has resigned his position and leaves the automobile field. He became identified with the International Liberty Union of Covington, Ky., on September 1.

Sutton Succeeds Packham—N. F. Sutton, for almost a year a member of the sales force of the General Motor Truck Co., has been promoted to the managership of the St. Louis (Mo.) branch. Mr. Sutton, who previously was connected with the Mitchell branch at Dallas, Tex., succeeds C. M. Packham, resigned.

Burns Joins Providence Co.—J. E. Burns, formerly manager of the Lee Motor Car & Supply Co., New Bedford, Mass., and later factory branch representative for the Jackson cars in Boston, has become identified with the Davis Automobile Co., Providence, R. I., which recently took the agency for the Regal cars.

Flagg Joins Standard Welding—Howard A. Flagg has become associated with the selling forces of the Standard Welding Co., Cleveland, O. Mr. Flagg has been connected with the seamless tubing industry for the past 15 years. At one time Mr. Flagg was sales manager of the steel tubing department of the Standard Welding Co.

Motsinger Rayfield Representative—N. H. Motsinger, Jr., is the latest addition to the Rayfield Carburetor organization. He formerly represented the Schebler Co. in Chicago, being Chicago branch manager for a number of years. Mr. Motsinger will serve the Findeisen & Kropf Mfg. Co., Chicago, Ill., in the capacity of factory representative.

Recent Changes in Seattle—Numerous changes have recently been made in the force of the Waterhouse-Sands Motor Co., Seattle, Wash. Earl Staley will hereafter be superintendent of the mechanical department, Will Culberson assistant to Mr. Sands in charge of the office. A. B. DeCasteline has recently joined the sales staff of the Gerlinger Motor Car Co., Seattle, taking charge of the Oldsmobile sales.

Winchell Retires—E. R. Winchell, well known Portland, Ore., dealer and formerly at the head of the Oregon Motor Car Co., has decided to retire from the automobile business in Portland. Mr. Winchell has sold his share to his associates, F. C. Riggs and W. C. Garbe. The management of the business will be under the supervision of W. C. Garbe, assisted by D. C. Warren. Mr. Winchell will tour through Oregon and California before announcing his plans.

Henshaw Gets Dodge in Boston—The uncertainty relative to the agency for the Dodge car in Boston was settled last week when the announcement was made that Charles S. Henshaw was to market the car. He has been in the motor industry since 1890, and a few years ago was manager of the E. R. Thomas branch in New York, going from there to the Alvan T. Fuller Co. Boston, to sell Packards. He has formed a company and will begin business October 1.

Tway Heads Haynes Branch — The Haynes Automobile Co., Kokomo, Ind., has opened a branch in Birmingham, Ala., at 400 South 21st street, in charge of Charles W. Tway and D. B. Williams, as assistant manager. From this branch all the business in the states south of the Ohio River and the West Indies is now being looked after or controlled. Here will be the headquarters of the traveling men and service mechanics for the entire territory controlled by the branch.

Join Studebaker Staff—To link more closely the factory sales organization with its force in the field, Sales Manager Ollier of the Studebaker Corp., has appointed the following staff of special representatives: New England, G. N. Jordon; South Atlantic, Edward A. Haybell; Central West, J. M. Opper; Southwest, L. A. Tilley; Pacific Coast, B. O. Willebrands. D. R. Murrell and R. C. Bridge have been promoted to be district representatives with headquarters at Norfolk, Va., and Salt Lake City, respectively.

Garage and Dealers' Field

"Sleuth" Looks for Bad Tires—"Follow Up" as it may be applied to the automobile tire business is demonstrated by a firm of dealers in Birmingham, Ala. This company sends a scout about town to note when any of the Ajax tires, which it handles, are showing signs of being worn so that a new casing is likely soon to be necessary. From his reports solicitation of business follows by telephone, call and letter.

Banquet for Maxwell Dealers—Dealers in the Maxwell in Ohio were given a banquet at the Southern Hotel, Columbus, August 28 as the guests of the company. The company was represented at the dinner by L. S. Smith, manager of sales in central Ohio; John G. Paine, manager of sales in northern Ohio, and W. D. Paine, supervisor of sales in the East. W. D. Paine acted as toastmaster. One of the features of the banquet was a moving picture show entitled "From Molten Steel to Automobile."

Hupmobile Makes Good Run—The Messrs. Card & Brown, of the Central Iowa Motors Co., which handles the Hupmobile in Des Moines, Ia., made a rather fast trip in their 1915 demonstrator from Detroit to this city. Leaving the Michigan automobile metropolis at nine o'clock Wednesday morning of last week, they reached that city at 9:37 p. m. on Friday, having covered a distance of 760 miles in 29 hours. The car consumed, all told, 2½ gallons cylinder oil and averaged 19¼ miles to the gallon of gasoline.

Accessories for the Automobilist

UNIVERSAL Piston Valve Motor—A new type of piston valve motor, Figs. 1 and 2, in which the valves open and close very quickly and with absolute silence, is announced by the Universal Mfg. Co., Minneapolis, Minn. In other respects the motor is like any conventional poppet valve design. It is an L-head type with block cast cylinders. The valves are operated by the connecting-rod and crank mechanism shown. The quick opening is obtained by the peculiar curve of the member that engages the valve crankshaft.

The construction calls for the intake and exhaust headers being placed on the top of the motor, as shown, the high position of the intake manifold giving a very accessible carbureter location, and there is no chance for missing, caused by condensation, to occur.

In this engine the intake valve opens 5 degrees after top dead center and closes 45 degrees after bottom dead center. The exhaust valve opens 35 degrees before top dead center and closes 10 degrees after top dead center. The quick opening and closing of the valve give added power for the weight, it is claimed, and the small percentage of power absorbed by the valves and the valve mechanism is said to make the engine desirable for motor car service. It is a simple motor from a manufacturing point of view and can be fitted with almost any type of ignition. In the lubrication of this motor there are two reservoirs, one for the valve mechanism and the valves and the other for the remaining parts. Splash is employed throughout and when the valve oil supply rises too high there is provided an outlet into the main motor reservoir.

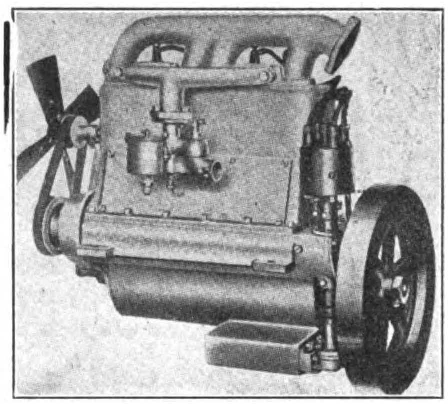

Fig. 1—Universal piston-valve motor

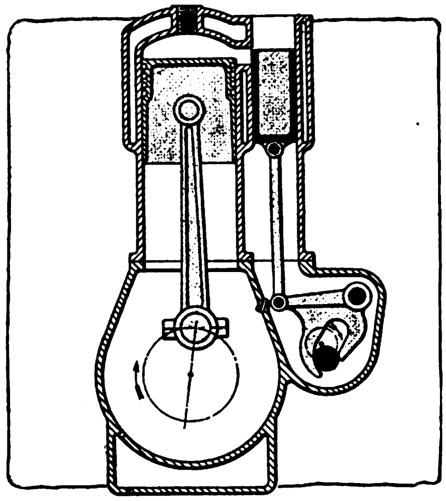

Fig. 2—Section through Universal motor

New Air Starter—An air cranking system, Figs. 3 and 4, which is somewhat similar in its general operation to the units of an electric starting and lighting system has just been brought out by the Auto Air Appliance Co., Baltimore, Md. Its operation is like that of an electric system in so far as it generates its own power in the form of compressed air, while the gasoline engine is running and later uses this stored energy to crank the engine. It consists essentially of a four-cylinder compressor-motor connected by silent chain to the engine crankshaft, this compressor pumping air to a tank. When desired for starting the air from the tank is sent back through the compressor, which turns over the engine. The entire apparatus necessary for this installation consists of the compressor, which is 12 inches long, 9 inches high and 5½ inches wide; a storage tank, 42 inches long; gauge, valves and an automatic governor for controlling the flow of air to and from the compressor, its functions being analogous to that of an automatic cutout in an electric-lighting system.

Fig. 4 shows the arrangement of the parts when installed. It will be seen that the compressor-motor is attached to the crankshaft of the engine by chain, and from the compressor lead two pipes, both terminating in the storage tank. One pipe sends air to the tank and the other is a feed pipe for air from the tank to the compressor. When the gasoline engine is started the compressor starts pumping air to the tank to a predetermined maximum pressure, and when this pressure is reached an automatic governor disengages the compressor clutch, thereby stopping further flow of air to the tank. When the pressure in the storage tank drops to a predetermined minimum the compressor again starts sending air to the tank. This arrangement then is similar to electric starting systems in which an automatic cutout is used for connecting and disconnecting the generator from the battery circuit, only in this case a governor disconnects and connects the compressor to the air line.

In order to crank an engine with this device it is necessary only to press the starting button shown in the illustration, this operation admitting air to the four-cylinder compressor, and the compressor, being connected with the engine crankshaft, turns it over, but the moment the pressure on the button is released the compressor ceases to be a motor and starts pumping air to the storage tank. The release of the starting button puts the governor in operation to perform this function.

When acting as a compressor, only two of the four cylinders are in use, and according to a statement from the company, the tank can be filled with air to a maximum pressure of 250 pounds in 5 minutes if the car is operating at a speed of 30 miles per hour. This is decreased to 15 minutes should the car be traveling 10 miles per hour. A test by the maker has shown that with air at 235 pounds pressure in the tank a 30-horsepower engine can be started thirty-five times without exhausting the tank. The turning speed of the gasoline motor is 200 r.p.m.

The compressor-motor is built like an ordinary gas engine. The cylinders, pistons, rings, etc., are iron castings, the crankcase aluminum and the connecting-rods drop-forgings. Oiling is by splash.

It is obvious that with a storage tank

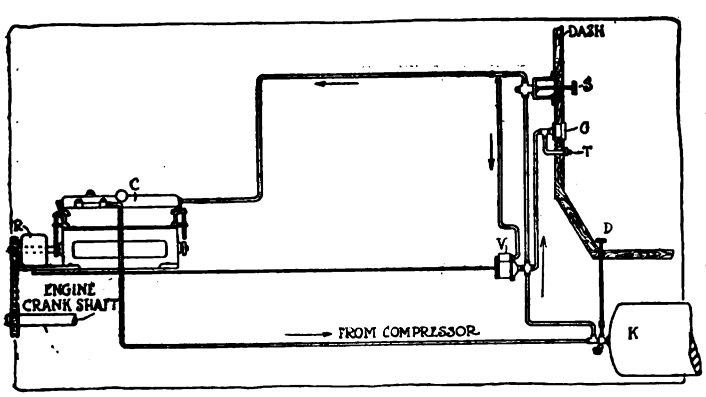

Fig. 3 — Right—Auto air appliance starter attached to motor

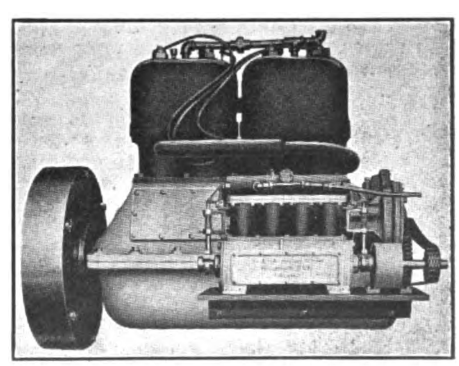
Fig. 4—Left—Starter piping layout, showing connection to motor and tank, and dash control



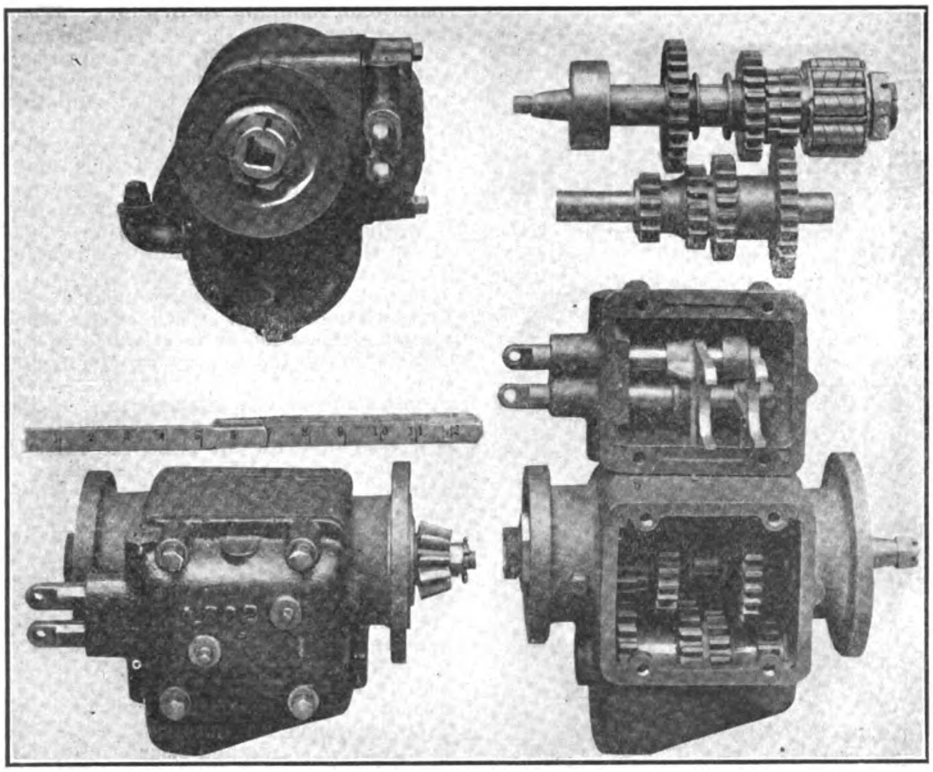


Fig. 5—Northern small car gearset. This model is for attachment to the rear axle. Another type is made for unit power plant constructions

with 250 pounds air pressure, some of this can be used for purposes other than cranking, and the device just described uses surplus air for inflating tires and for cleaning.

Northern Small Car Gearsets—Two types of three-speed sliding gearsets are manufactured by the Northern Engineering Works, Detroit, Mich., for small cars. From 12 to 18 horsepower can be transmitted. One is for attachment to the rear axle and the other is for use in connection with a unit power plant construction. The former is shown in Fig. 5.

With the exception of the details noted both gearsets are identical. The gears have ⅝-inch face, seven to nine pitch and all the principal gears are cut from 3.5 per cent. At the front, Hyatt roller bearings are employed, while at the rear double-row ballbearing bearings are found. The case is made of cast iron, and the shifter rods are assembled in the cover, providing both accessibility and compactness. The ratio on second is 1.73 to 1, on low 2.98 to 1, and reverse 3.64 to 1.

Fowler Flex-Spring Shock Absorbers—A new type of shock absorber for Ford cars is indicated in the device illustrated in Fig. 6, and which is manufactured by the Fowler Lamp & Mfg. Co., 57 East 24th street, Chicago, Ill. The price complete with studs and grease cups is $8 per set.

Highway Tire Straps—To prevent skidding, tire wear, punctures and blow-outs, a flexible leather and steel tire covering has been brought out by the Bukolt Mfg. Co., Stevens Point, Wis. The name of the device, Fig. 7, is Highway Tire Straps, because it consists of a series of straps linked together. The device may be easily and quickly removed when desired. The price for a 28 by 3 shoe is $8.80 and for a 38 by 5 $22.

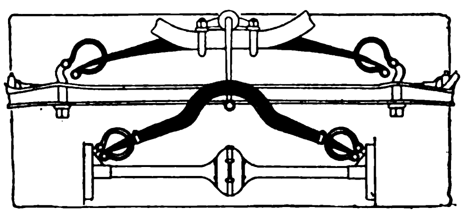

Fig. 6—Fowler Flex-Spring shock absorbers

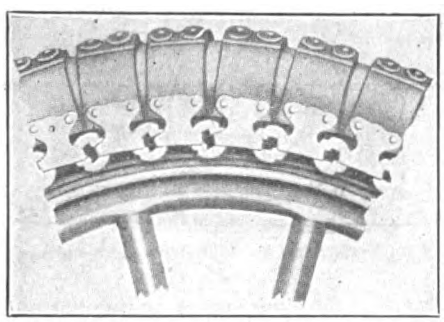

Fig. 7—Highway tire straps

Curtis Auto Trailer—The trailer shown in Fig. 8 is a two-wheeled device in which the springs are mounted on an underslung frame and in which a special form of hitching tree is used so that the trailer may be clamped to the back of any car. This device permits the car to turn at any angle and yet the trailer will follow directly in its track. The body is 41.5 inches wide and 7 feet 3 inches long. Its capacity is 1,000 pounds. The price with steel tires and 1,000-mile axle is $60; with rubber tires and 1,000-mile axle, $75, and with roller bearings and rubber tires, $90. It is manufactured by Alex R. Curtis, 1405 Hennepin avenue, Minneapolis, Minn.

Sheldon 3-Ton Axle—The 3-ton worm gear axles now being delivered by the Sheldon Axle Co., Wilkesbarre, Pa., follow the same general design of the previous models.

The worm is made of special heat-treated steel and ground by special machinery. The worm wheel is cut from special formula bronze and by special machinery for this work. The worm and worm wheel are carried in a worm carrier—a very substantial casting machined by special jigs and fixtures to receive the worm and worm wheel in perfect alignment. The methods employed in machining the worm carrier insures positive adjustment at all times and renders the assembly unit absolutely fool-proof.

Ball bearings are used throughout, giving the truck buyer a worm gear axle in which there is absolutely nothing to get out of alignment.

The top of the worm gear carrier is drilled and tapped for an eye bolt to facilitate the removal of this unit, which contains the worm, worm wheel, radial bearings, thrust bearings and differential bearings. The differential thrust bearings are mounted in the axle housing proper.

All differential gears and pinions are 3½ per cent. nickel steel, heat treated. The differential spider is drop-forged and 3½ per cent. nickel steel, heat treated and ground to size.

The axle shafts are 3½ per cent. nickel steel, heat treated, and accurately proportioned to insure uniform stresses throughout.

Special attention has been given the subject of brakes on this axle, with the idea of securing the proper brake area, and at the same time using 36-inch diameter wheels and securing proper clearance between the brake parts and the skid chains. The axle is equipped with 20-inch brake drums and has four 2½-inch wide internal brakes. This design gives ample brake area and at the same time permits the use of 36-inch wheels with anti-skid chains, without interfering with any of the brake parts. This design also has the added advantage of protecting the brake drum and lining from mud and dirt, which works much damage with these parts.

No provision is made for radius or torsion rods. The braking and driving torque are taken through the springs.

VOL. XXXI NEW YORK—THURSDAY, SEPTEMBER 17, 1914—CHICAGO No. 12

The AUTOMOBILE

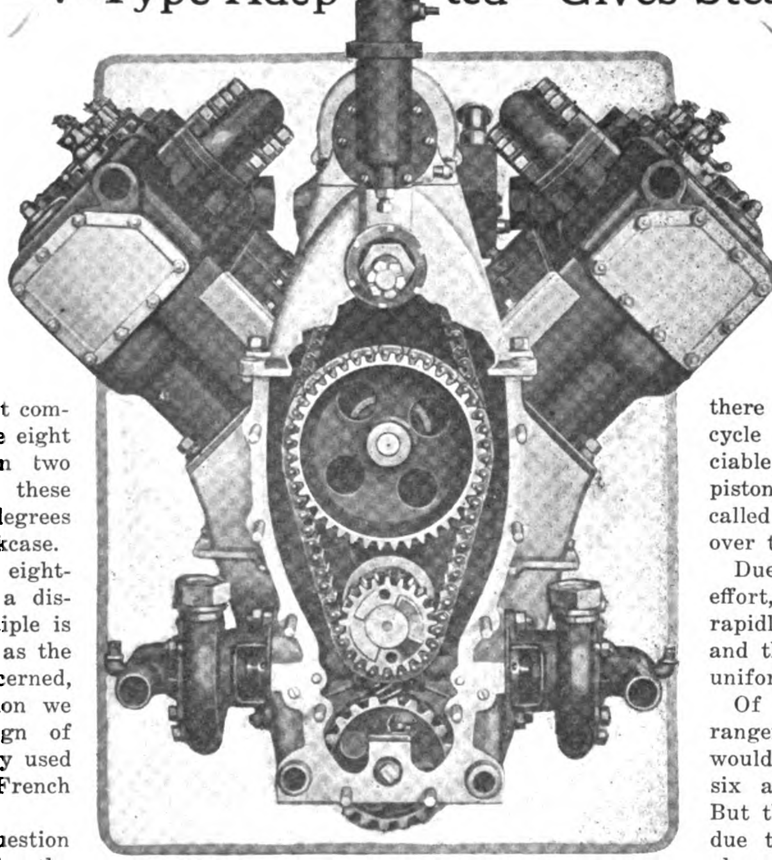
Eight-Cylinder Motor for 1915

Cadillac Introduces French Motor Design as Stock for Next Year—V-Type Adopted—Gives Steady Torque

FOR next year the Cadillac Motor Car Co. is using an eight-cylinder motor as its stock equipment, this marking the début of this type of motor in the stock-car field in America. The motor is what has been known as the V-type developed some years ago by the DeDion Bouton company in France, and marketed since then by that company as stock models. The eight cylinders are arranged in two groups of four each, and these groups are mounted at 90 degrees to each other on the crankcase.

Although an American eight-cylinder motor comes as a distinct innovation, the principle is now new, not even so far as the automobile industry is concerned, and if we turn to aviation we will find that this design of motor has been successfully used by one of the best known French makers.

Naturally, the first question which will be asked is why the addition of two cylinders will make such a justifiable difference in performance as compared with a six. In the eight there are eight power impulses during each complete cycle of two crankshaft revolutions; that is, there is a power impulse every quarter turn of the crankshaft and thus there is no intermission between them, but rather an overlapping so complete that the turning effort is practically constant. In the six there is a power impulse every one-third revolution of the crankshaft, and though there is always a turning effort upon the crankshaft, it has more fluctuation due to the longer interval between impulses. In the four-cylinder engine an impulse occurs every half revolution, and there are obviously periods in the cycle when there is no appreciable force exerted by any of the pistons. The flywheel is then called upon to carry the shaft over these power lapses.

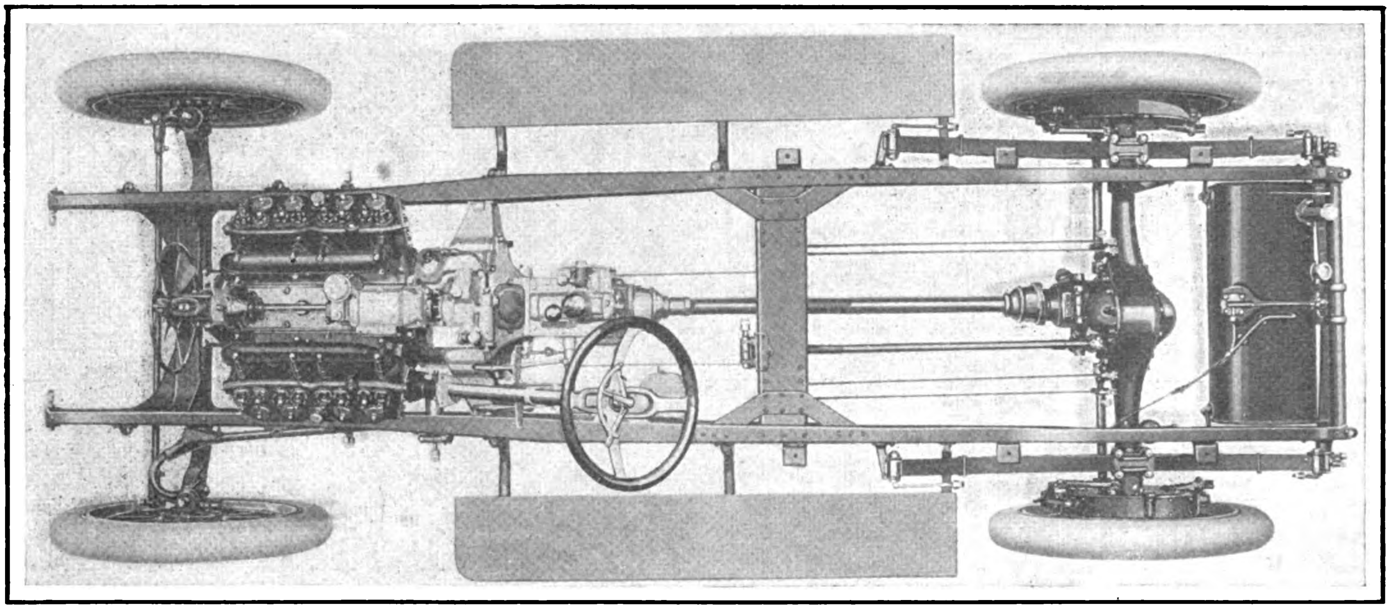


CADILLAC EIGHT-CYLINDER MOTOR FOR 1915

This photographic reproduction shows the front end of the new Cadillac eight-cylinder motor, which the company will use in its 1915 cars. There are two groups of cylinders, each a block casting of four cylinders, mounted at 90 degrees to each other. The cylinders are 3 1-8-inch bore and 5 1-8-inch stroke. The piston displacement is 314 cubic inches; the horsepower rating is 31.28. In dynamometer tests the motor shows 70 horsepower at 2400 r.p.m. The crankshaft is identical in design with that used in a four-cylinder car, and the camshaft carries the same number of cams as in a four-cylinder design. This new motor weighs approximately 60 pounds less than the four-cylinder Cadillac engine used this year. There is but one carbureter used

Due to this continuous turning effort, the six-cylinder motor has rapidly come into prominence, and the eight has an even more uniform torque.

Of course, the simplest arrangement of eight cylinders would be all in line just as the six are arranged or the four. But this would be impracticable, due to the extreme length and also to the abnormally long crankshaft which would be necessitated, while the crankcase for such an engine would be very heavy. To eliminate these difficulties the cylinders are arranged in two sets of four opposite to each other at an angle of 90 degrees, the same angle as it would be necessary to set the two series of four crankshaft throws were the cylinders arranged all in line. This placing of the cylinders in



CADILLAC CHASSIS FOR 1915, SHOWING EIGHT-CYLINDER MOTOR WITH UNIT GEARBOX

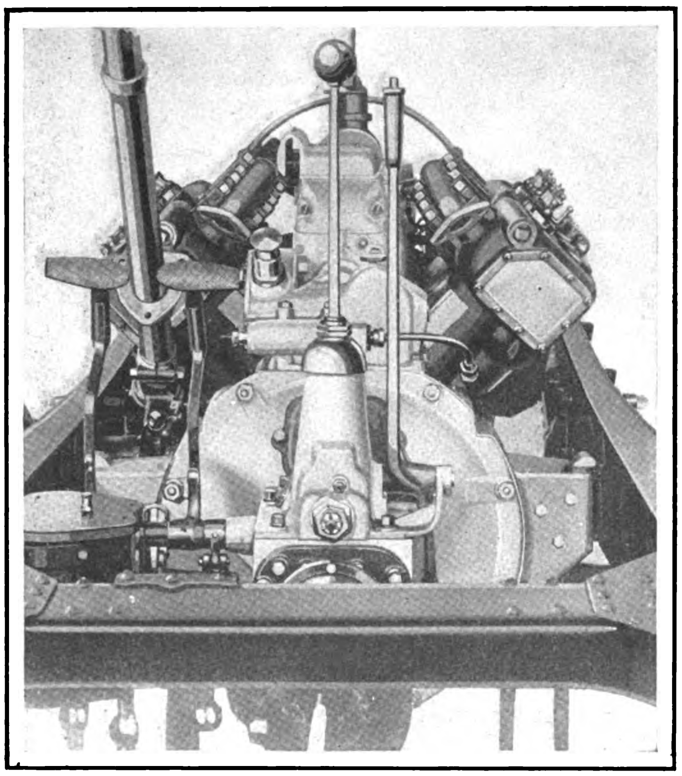
For next year the Cadillac company has discarded the four-cylinder motor and is using an eight-cylinder design, which gives a very compact power plant, one actually shorter than the four-cylinder predecessor. The small flywheel is entirely enclosed and the three-speed gearbox is a unit with the motor. For the first time this company has placed the steering wheel on the left with center control. A single-reduction Timken axle design is used with a set of spiral bevel gears instead of the conventional bevel type. The Delco electric system is continued. The wheelbase is 122 inches, or 2 inches longer than this year

sets at an angle of 90 degrees to each other gives the V form.

Arranged in this way, the eight-cylinder motor is no longer than a four-cylinder one of equal bore. As compared with a six, it has about 30 per cent. less length, resulting in a shorter crankcase—a weight reduction factor. In addition, its crankshaft is of the same form as that of a four, the throws being all in one plane, whereas those of a six crankshaft are in three planes, it is a simpler manufacturing job. Further, the shorter shaft is less given to periodic vibration, the camshaft is also shorter and less prone to whipping.

Considering the weight of a six and an eight, the shorter crankcase, shorter crankshaft and camshaft, lighter reciprocating parts and flywheel give the latter a distinct advantage, considering that both engines have the same power. In the Cadillac case, the new motor has proven to be fully 60 pounds lighter than the four-cylinder engine formerly used. This is because it is shorter and has lighter reciprocating parts.

Because each set of cylinders may be cooled separately and due to the angle of the jackets there is no chance for any of the water to get into pockets, the cooling of a V-shaped eight is superior to that of a six or a four. The natural tendency is for the water to flow upward through the jackets. Further, the water tends to rise to the hottest points of the jackets.



REAR VIEW CADILLAC MOTOR, SHOWING DELCO UNIT IN V CYLINDERS

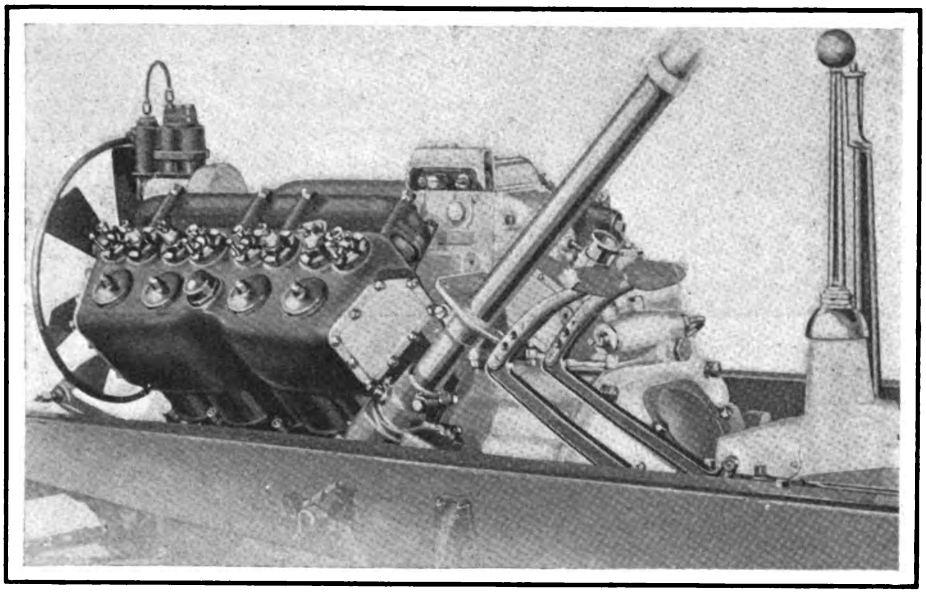
The angular space between the two groups of cylinders affords ample space for the fan and tire pump in front, the carbureter near the middle and the Delco unit at the rear. There is a separate exhaust pipe for each cylinder group, the flanged ends on these pipes being shown. This illustration shows the compact gearbox, a unit with the motor. For next year a multiple-disk, dry-plate clutch is used, composed of fifteen high-carbon steel plates 7.75 inches in diameter. The set of plates driven by the flywheel are faced with wire-mesh asbestos

Aside from the purely mechanical advantages of the newest type of gasoline motor, the car owner is specially interested to know just how these above-mentioned advantages affect the working of the car so far as the actual driving of it is concerned. It is only natural for the average man to say to himself that perhaps the eight is theoretically superior to the six, but that when it comes to actual road work there is probably little difference.

On the Road

The writer must admit that prior to some actual road work with the new Cadillac he was somewhat inclined to be in the sceptical division and questioned the appreciable advantage of tacking on two extra cylinders. A 60-mile run over rolling country where hills abounded, some quite steep, resulted in complete conversion to the eight and great surprise at its performance, however.

Gearshifting proved to be almost an unnecessary operation, speeds anywhere from 2 1-2 to 55 or 60 miles an hour being attainable on high gear. The quick acceleration from slow running to passenger train travel with no apparent effort whatever was truly remarkable. Bad stretches of road, turn outs for slow-moving vehicles and other traffic obstructions very rarely made it necessary to drop into second gear. Nor was this high gear driving done with any effort; the car controlled with the throttle alone just as if it were an electric responding to a current control lever. There was an undeniable feeling of security in driving the car, for the idea of killing the motor does not enter your mind the reserve power is so great.



THREE-QUARTER VIEW CADILLAC EIGHT-CYLINDER MOTOR FOR 1915

Each of the two cylinder castings contains four L-shaped cylinders. The intake valves are tulip shaped to permit of freer flow of gas into the cylinders. The exhaust valves are conventional poppet shapes. Over each cylinder bore is a removable cap which gives access to the waterjacket and to the combustion chamber. Between the second and third cylinder in each block the breather pipe is brought up through the cylinder casting. In rear of the fan is the power tire pump for tire inflation. The two groups of cylinders are mounted at 90 degrees on an aluminum crankcase

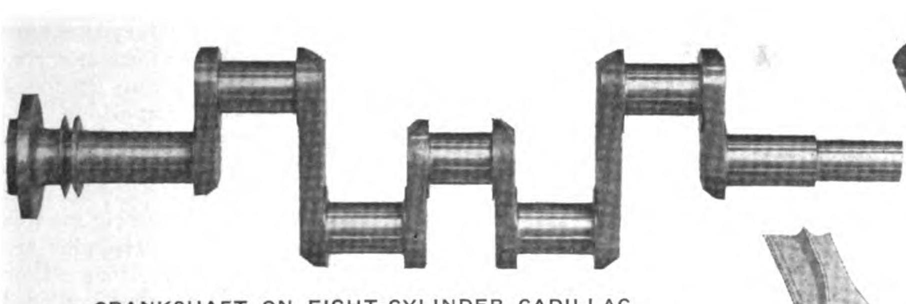
S. A. E. Horsepower 31.28

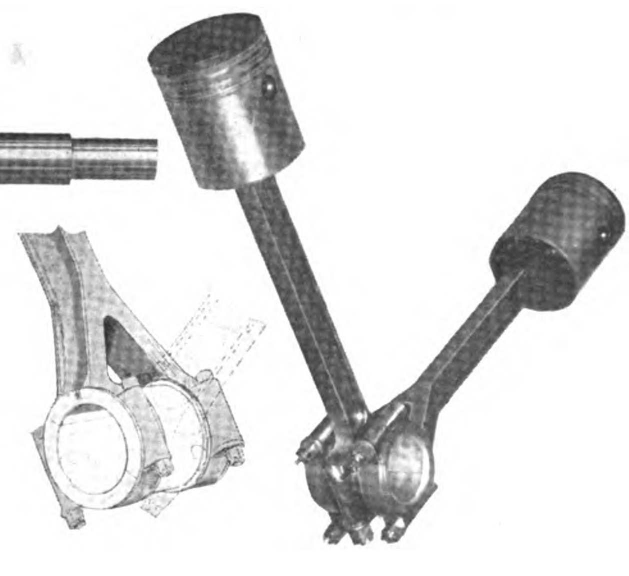
Considering the Cadillac motor in detail, one is struck with the high speed, high efficiency machine which has been produced almost without precedent or previous experience with this type. The two sets of four cylinders are each block cast and present much the same general appearance as any other block of four. The bore is 3 1-8 inches and the stroke 5 1-8 inches, giving a total piston displacement of 314 cubic inches. The S. A. E. formula, which is really not applicable to this motor, gives it a rating of 31.28 horsepower. On dynamometer tests it has developed 70 horsepower at 2,400 revolutions per minute. The power curve herewith serves to indicate the output at various speeds.

Connecting Rods in Pairs

The blocks of cylinders bolt to the copper-alloy aluminum crankcase which is common to both and which is split horizontally into upper and lower sections, the lower portion being the oil base. The upper half carries the crankshaft which has three main bearings. Both sets of connecting-rods connect to this shaft, one throw bearing taking care of a pair of rod ends, in opposite cylinders. In order for both to fasten to the same bushing, one rod has a yoked end, the other rod end fitting within the yoke arms. Two caps are thus required for the yoke rod, one for each arm of the yoke. These fit around the outer part of the bushing, gripping it rigidly, due to the cap bolts and in addition pins go through the rod into the bushing so as to insure the two moving together. The other rod fits around the bushing within the yoke and is free to turn on the bushing. Thus in operation the bearing for the yoke-end rod is the inner surface of the bushing against the shaft, while that of the other rod is the other surface of the bushing. These bearings have babbitt linings in reinforced phosphor bronze shells. Thus there are four connecting-rod bearings on the crankshaft just as a four-cylinder motor would have. The length of the crankshaft to the outer ends of the end bearings is 26 1-2 inches.

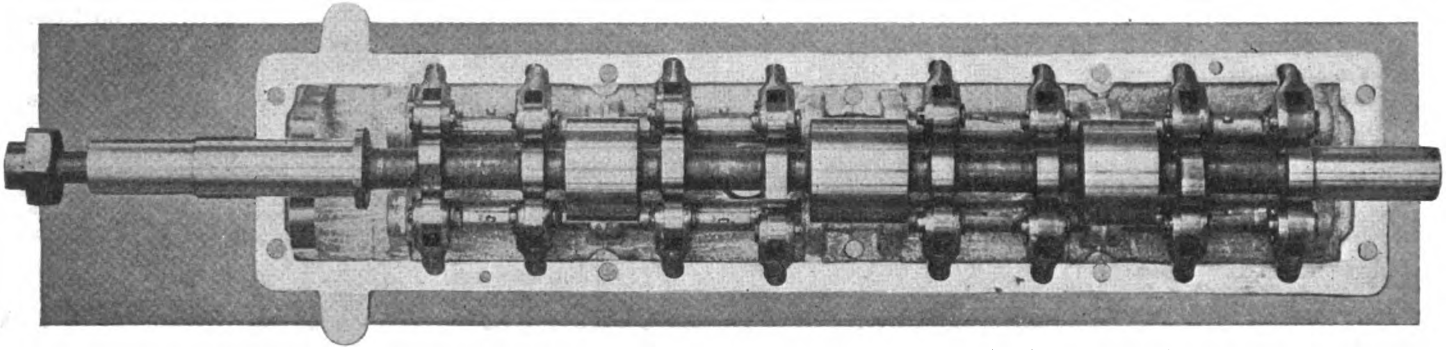
Directly above the crankshaft is the single camshaft with eight cams, one operating two opposite inlet valves or two exhausts as the case may be. The cam assembly is on the underside of a plate which bolts to the top of the crankcase between the two blocks of cylinders. Pivoted to this plate also are the small arms which are interposed between the ends of the push rods and the cams so that the lift will be straight upward instead of having a side thrust component. The camshaft has five bearings.



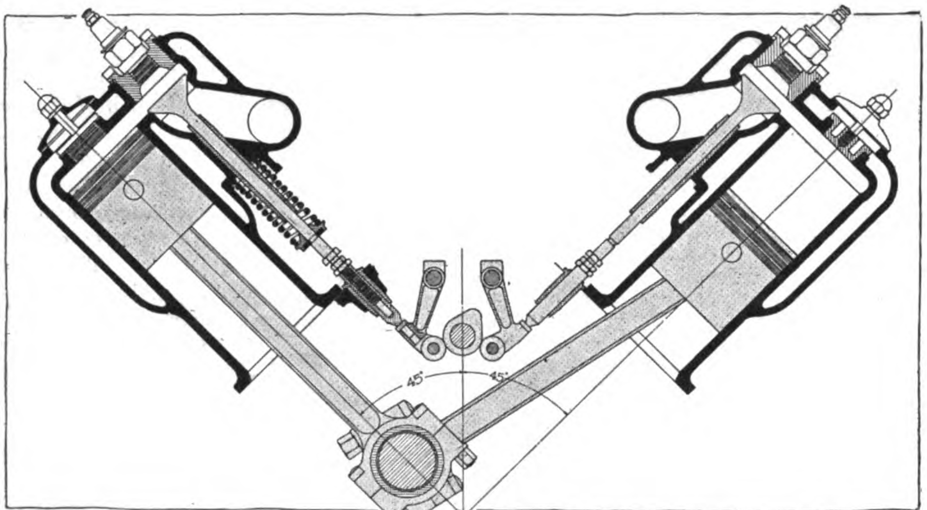


CRANKSHAFT ON EIGHT-CYLINDER CADILLAC

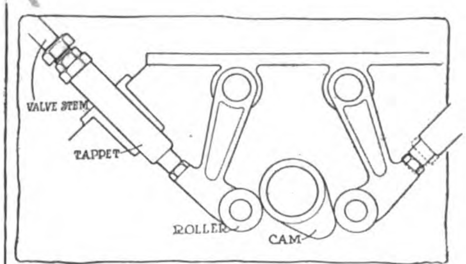
A three-bearing crankshaft is used with the throws at 180 degrees, as in a four-cylinder design. Two connecting rods attach to each crankpin, this being possible by having one connecting rod with a split or forked lower end, and the other a single end to fit between the forks. This shaft is no longer than that used on a four-cylinder motor with the same cylinder dimensions. The connecting rods and pistons are in pairs, two connecting rods attaching to each crankshaft throw. One connecting rod is forked at the lower end and the other one fits between the forks. One bushing is used for both rods, this bushing being pinned to the forks of the outer rod and floating in the inner rod, which merely oscillates on it. The rods are exceptionally light



Single camshaft used in eight-cylinder Cadillac motor. On it are eight cams which operate the sixteen valves in the motor. Each cam works two valves through the rollers shown on opposite sides of it. The shaft is carried on five bearings



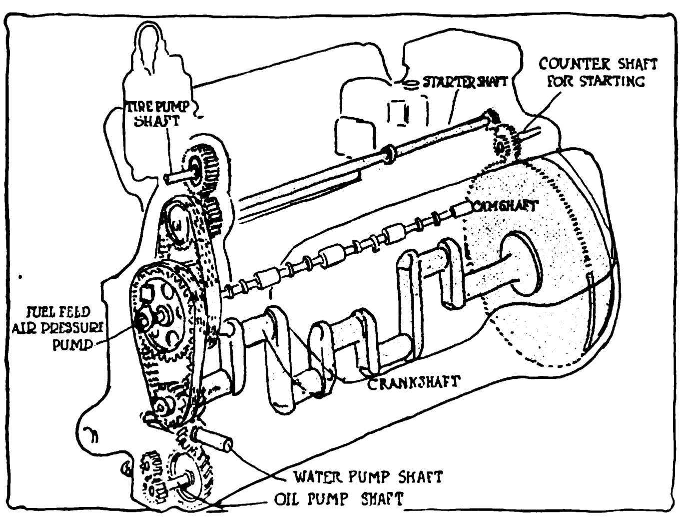
Cross-section of Cadillac eight-cylinder motor with the cylinders mounted in two **groups of four cylinders each at an angle of 90 degrees. The single camshaft is located directly above the crankshaft, and the means whereby one cam operates the two intake valves for the opposite cylinders is shown. Note the tulip-shaped intake valves, this design of head giving a free flow of inrushing gases**



The valve operating mechanism of the Cadillac motor, showing how one cam operates two opposite valves. The cam bears against the rollers in the ends of the small arms, which are pivoted to the plate above and which are interposed between the ends of the push rods and the cams, so that the lift will be straight upward instead of having a side thrust component. Adjustment of the valves is obtained in the usual way by lengthening the tappet. The upper part of the tappet **screws into the lower and the two are locked by a nut. The position of the cylinders makes the valves extremely accessible**

Vertically in line above the camshaft and crankshaft is the generator shaft which drives the fan and the combined motor-generator mounted on top of the camshaft plate and between the cylinder blocks, and also carries a gear which may be meshed with that of the tire pump carried at the forward end of the motor.

Both camshaft and generator shaft are driven by silent chains completely housed at the front end. The camshaft carries two sprockets, the outer carrying the chain running down to the crankshaft sprocket and the inner driving the chain which passes around the generator shaft sprocket above.



Shafting system in the Cadillac eight-cylinder motor, showing the use of two silent chains, one driving the camshaft and another driving from the camshaft to the shaft driving the Delco system. The tire pump is driven by spur gear. There are two water pumps on the cross shaft below the crankshaft, and from this shaft in turn drives the gear oil pump indicated

At the front of the engine and below the crankshaft is a transverse shaft driven from the crankshaft by spiral gears. A centrifugal water pump is located on either end of this shaft, one taking care of each block of cylinders.

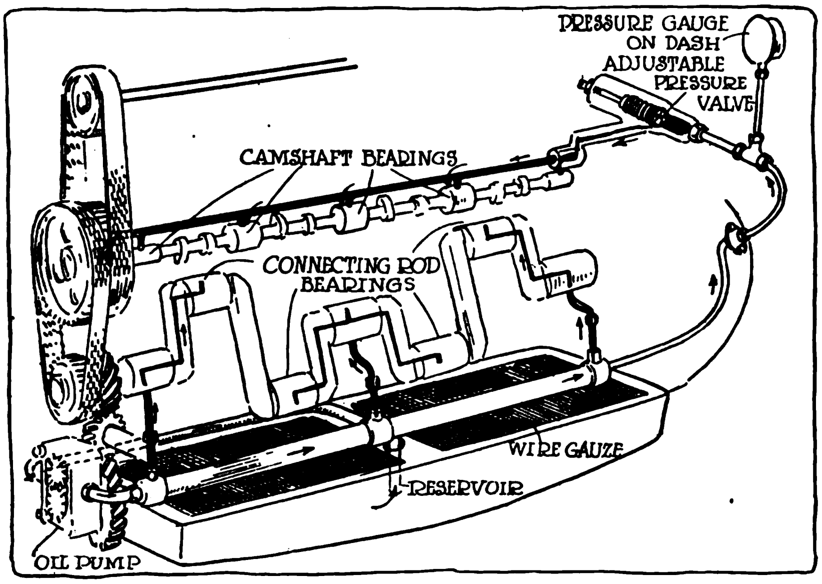
Light Weight Parts

In order to secure the accurate balance necessary to a high speed motor of this type so that it will be practically free from vibration, the pistons and connecting-rods are machined to very close limits. Uniformity of weight is important. Remarkable lightness of these parts has been attained due to the use of a special alloy steel for the rods which has great strength with extreme lightness, and also to the special form of the cast iron pistons, each of which has three ring grooves with three thin steel rings per groove. The wrist pins are fixed in the connecting-rods and oscillate in the pistons. They are constructed of chrome nickel steel tubing, case hardened and 5-8 inch in diameter.

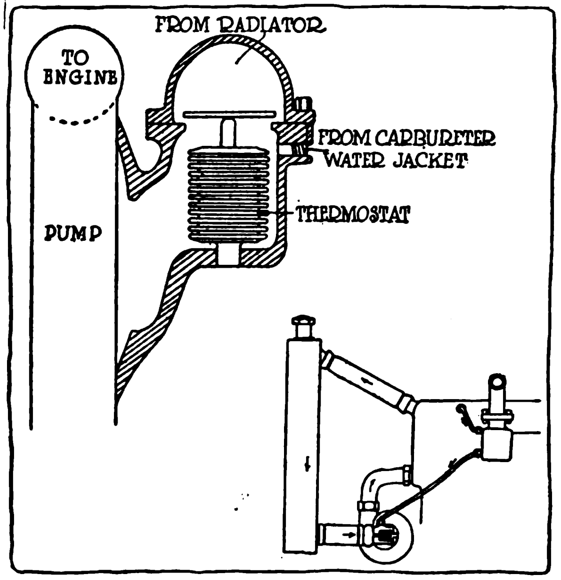
As another indication of the refinement to which this motor has been subjected, the inlet valves are of tulip shape so as to facilitate the intake of the gas, while the exhausts are of the flat type and of tungsten steel.

Order of Firing

In firing, the order alternates from one side to the other, so that there is a power impulse first from a cylinder on one



Lubrication of the eight-cylinder Cadillac motor. The pump draws the oil up from the reservoir and forces it through the pipe running along the inside of the crankcase. Leads run from this pipe to the crankshaft main bearings and thence through drilled holes in the shaft and webs to the rod bearings. It also is forced from the reservoir pipe up to the pressure valve, which maintains a uniform pressure above certain speeds, and then overflows from this valve to a pipe extending parallel with and above the camshaft. Leads from this latter pipe carry the oil by gravity to the camshaft bearings and chains. Pistons, cylinders, etc., are lubricated by the overflow thrown from the rods



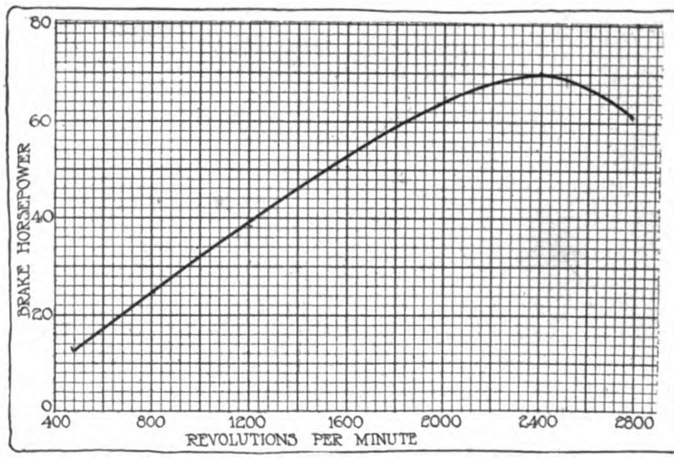
The temperature of the cooling water in the new Cadillac motor is controlled by a thermostatic arrangement, the principle of which is shown in the sectional sketch. When the water is below the desired temperature the thermostat is contracted and allows the valve to seat, so that only that part of the water going through the carbureter jacket and the water jackets of the cylinders is circulating by means of a by-pass

side followed by an impulse from a cylinder on the opposite side. The order of firing is indicated below:

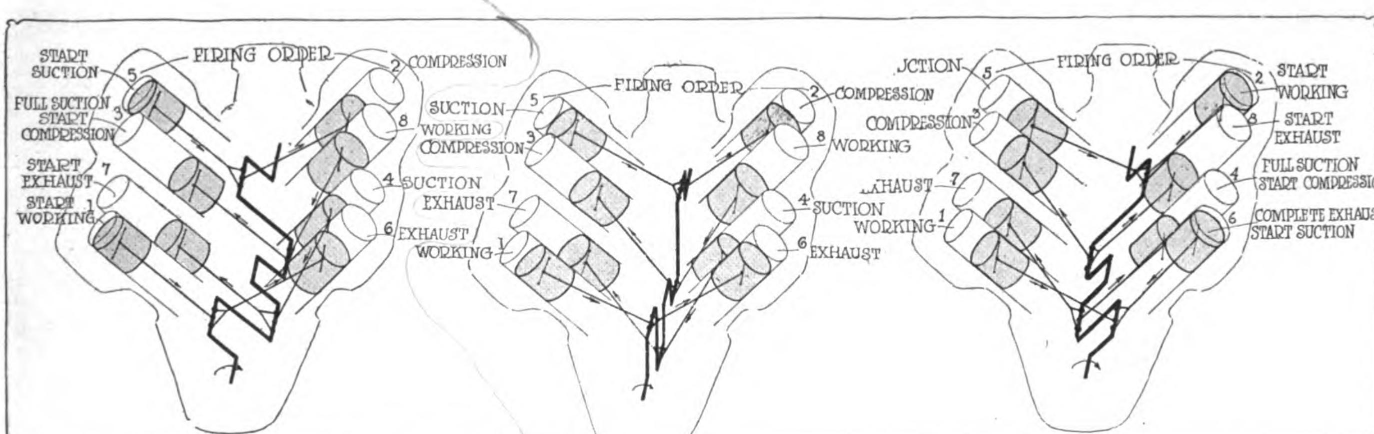
Front
6X — X1
4X — X7
8X — X3
2X — X5
Rear

That is, No. 1 cylinder on the right fires first, then No. 4 on the left, No. 3 right, No. 2 left, and so on. As to the timing, the inlet valves open at top dead center and close 45 degrees after bottom dead center, while the exhausts open 45 degrees before bottom dead center and close at top dead center.

The Cadillac single-jet carbureter, specially adapted to this type of motor, is used. It occupies a position midway of the engine and between the cylinder blocks. A form of U mani-



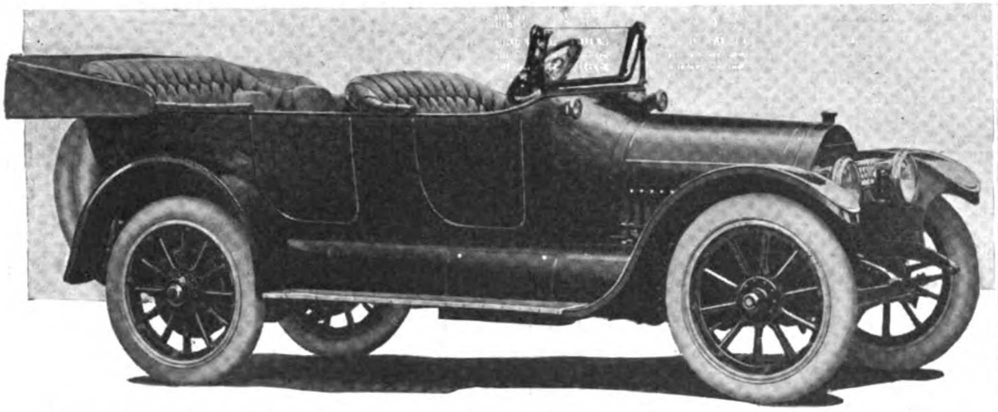
Horsepower curve of Cadillac eight-cylinder motor

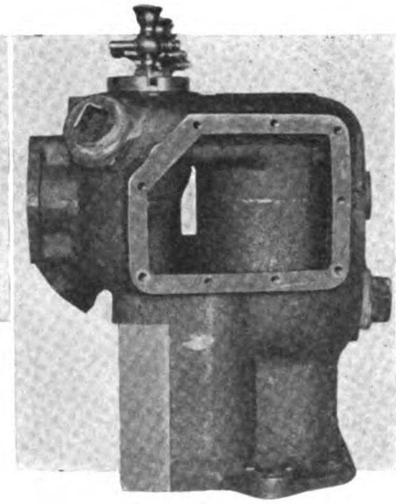


Showing the relative positions of the pistons and what is taking place in each cylinder when No. 1 cylinder commences its working stroke. All pistons on the left are either all the way up or all the way down, while all four on the right are midway

The order of events in the cylinders when the plane of the throws is vertical. The various parts of the cycle are well under way in the cylinders. The function that each cylinder is performing is indicated in the lettering

The shaft has now revolved through 90 degrees and the piston positions of the two sets are just the reverse of what they were in the first diagram. Those on the left are midway of their travel. The fourth cylinder in the right block is just firing

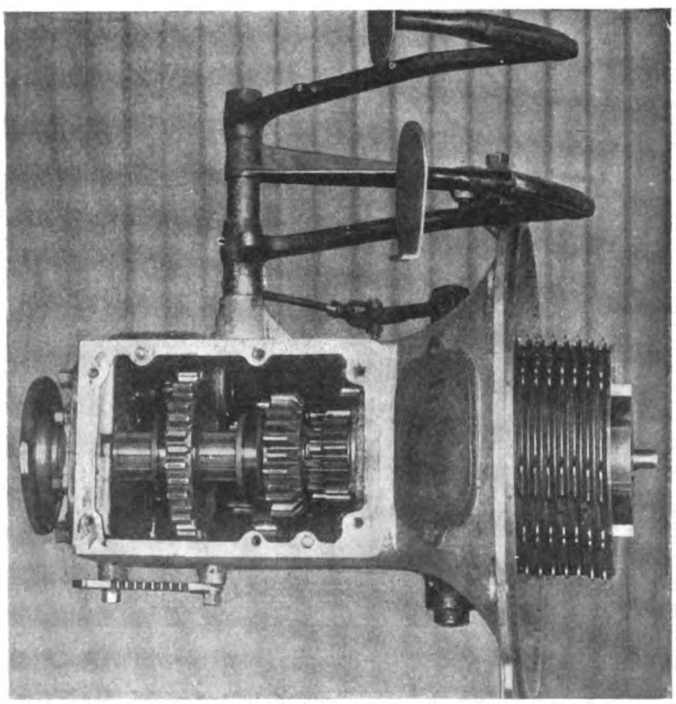




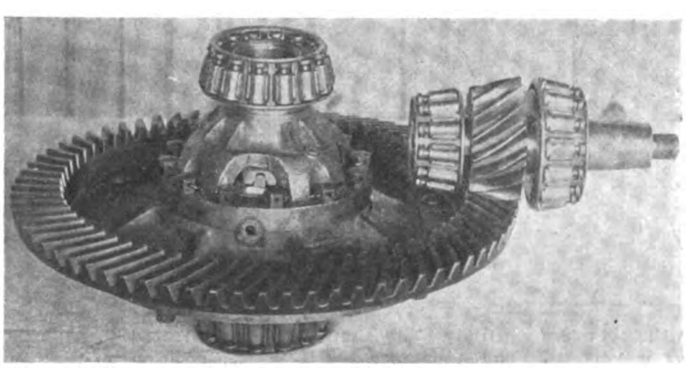
The 1915 Cadillac with eight-cylinder motor. Wheelbase 122 inches. At the right is one of the cylinder castings showing the open water space from end to end

fold runs from it to the two cylinder blocks, the distribution to the various cylinders being done within the casting.

An entirely new feature to automobiles is the application of thermostatic control to the temperature of the cooling water, so that, in running, this water is maintained at nearly a constant temperature. In principle this thermostatic regulation is the same as the form used in connection with the heating systems of houses.



Top view of three-speed gearset and multiple disk clutch used on new Cadillac. This gearset is a unit with the motor, a new construction with Cadillac. It is the first year in which a multiple disk clutch has been used by this company



Spiral bevel gear is used in the rear axle of the Cadillac. The axle is of Timken design and construction, excepting that these spiral bevels are manufactured in the Cadillac factory

Thermostatic Control

In the Cadillac application, there is interposed in the water pump line for each set of cylinders a thermostat which is simply a small coiled copper tube containing a liquid which expands or contracts in accordance with the temperature, thus slightly lengthening or contracting, its total movement being 1-4 inch. This thermostat is in connection with a valve so that when it expands, it raises the valve from its seat, this valve controlling the flow of water to the radiator from the pump. A by-pass connects with the water jacket of the carbureter, and when the engine is started, the water is naturally cold. Therefore the thermostat is contracted and its valve on its seat. Thus the radiator water is shut off, the circulation being simply through the water jackets of the cylinders, through the by-pass tc the carbureter iacket and thence back to the cylinders.

There is thus only a small part of the water circulating, and when this heats up, the thermostat begins to expand and lift its valve from its seat, letting the radiator supply flow into the system. This action continues back and forth so that the water temperature is nearly constant.

Motor Lubrication

As regards motor lubrication, the engine incorporates a positive system of force-feed type. A gear pump located at the forward end of the motor and driven from the crankshaft takes the oil up from the oil pan in the lower part of the crankcase and forces it through a reservoir pipe running along the inside of the crankcase, from which pipe there are leads to each of the main bearings. The crankshaft and webs are drilled and oil is forced from these main bearings to the connecting-rod bearings through the drilled holes. The forward and rear bearings supply the rod bearings nearest them, while the center bearing takes care of the rod bearings on either side of it. The oil is then forced from the main reservoir pipe up to the relief valve which maintains a uniform pressure above certain speeds and overflows from this valve to a pipe extending parallel with the camshaft and above it. Leads from this latter pipe carry lubricant by gravity to the camshaft bearings and front end chains. Pistons, cylinders and piston pins get their oiling by the oil thrown from the lower ends of the connecting-rods.

As heretofore, the Cadillac uses the Delco combination electrical unit for cranking, lighting and ignition, the special eight-cylinder distributer being in unit with the motor generator. As has already been pointed out, the unit is driven as a generator from the camshaft by a silent chain, its shaft

The Automobile as Valuable as Railroad in War

Automobiles of Immense Service in France—Both for Army and Transporting Refugees—Private Motoring at Standstill—Cars Cannot Leave Paris

By W. F. Bradley

PARIS, Sept. 10—Automobiles were never so closely watched and never so highly appreciated as at this present moment. With railroad communication cut, with crowds fleeing in terror, with fierce fighting on every hand, the possession of a car is considered a valuable asset. The few old-school army officers who swore by horses and plenty of men have finally had to admit that their methods are out of date.

The automobile is as valuable, if not more valuable, at this present moment, than the railroad.

Because they recognize their value for good or for evil, the authorities in France have imposed hard restrictions on the use of cars.

No man can use a car unless he has a special permit from the military authorities; that permit must be shown every few miles. None but military cars can be on the road after dusk.

Paris Closed at Noon

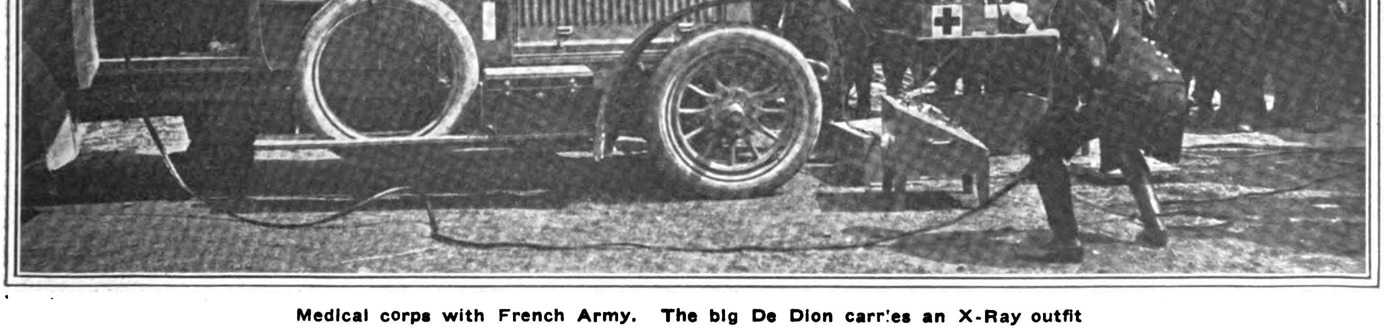
Yesterday the government issued orders that no more cars should be allowed to leave Paris after 12 noon. As it was known that the government was preparing to transfer to Bordeaux, and that the German troops were making desperate efforts to invest Paris, there was a wild stampede for the western provinces. Paris is surrounded by fortifications and gates. All those gates had to close at noon. Cars were loaded up with baggage, passengers were piled in with no other seat but the top of the trunks. At the Porte Maillot, one of the most important gates of Paris, the scene almost baffled description. In an unbroken stream cars poured through. They were of every type from the single-cylinder runabout to the loud-voiced, semi-racer and the handsome limousine. They were similar in one respect: they were packed with baggage and passengers to more than three times their ordinary load. As it was practically certain that no gasoline could be found on the road, enough had to be carried for a journey of 200 to 400 miles. All the oil, tires, spares, etc., that could possibly be required had to be taken aboard.

Exodus from the Capital

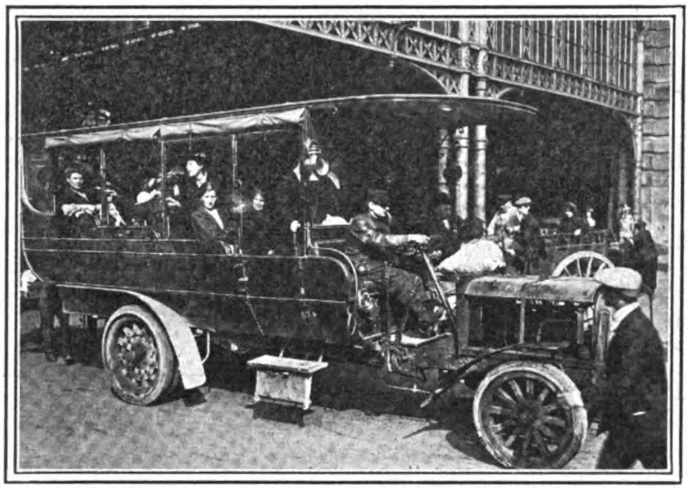
As much furniture as could be saved was packed into the car; trunks were strapped on the running boards until the sides of the car disappeared. In one case, when the car had been loaded in this way, the ladies could not climb back into their seats. A tall cavalry officer who was passing lifted them in. Rich families possessing more than one car put their women folk in one and their valuables in the other. A family of seven had crowded themselves into a car made for four, and by some superhuman feat had got trunks and bedding in with them. The driver's hat blew away as he neared the gates, but so great was his fear that he might be shut in that he did not stop.

An American family was being taken on a small car to the Packard garage just outside the city, where they were to be transferred to a big car carrying them to the coast. When they got through the gates the terror of the head of the family was so great that he threatened and persuaded the chauffeur to continue with the little car, rather than lose the time necessary for the transfer.

On the main roads just outside the city the automobilists overtook processions of peasants in lumbering farm wagons



Medical corps with French Army. The big De Dion carries an X-Ray outfit



Refugees from Belgium and Northern France leaving Paris

who had been turned out of the farms within range of the forts forming a belt round the city. Wizened old grandmothers and wrinkled old grandfathers shared the wagons with healthy children, ricketty furniture, bedding, perambulators, fowls and domestic animals. Heavy wagons loaded with cartridges made in the automobile factories transformed for this purpose traveled along; an automobile towing an armored aeroplane claimed a right of way and was given it.

Many of the drivers of the cars were merely desirous of placing their women folk and children in a place of safety. When this had been done the men would return to Paris to take up military duties. This meant that they had to travel 400 miles or more without a stop, for failure to be back on time would cause them to be marked down as deserters.

One of the engineers of the Pipe Automobile Co., Brussels, has given me interesting particulars of how automobiles were made use of in opposing the advance of the Germans into Belgium. Belgium had no armored automobiles, but the Pipe company undertook to place some at the disposal of the army at very short notice. A number of 80 horsepower chassis were prepared, and in conjunction with a manufacturer of fireproof safes who had his works next door, chrome nickle steel plates were put round the platform body on which a quick-firing gun had been mounted. The wheels and the gasoline tank were protected in the same way, while the driver was protected by an inclined plate coming practically level with his eyes. All the plates were fastened at the base only, thus giving a certain amount of flexibility which tended to deflect the bullets.

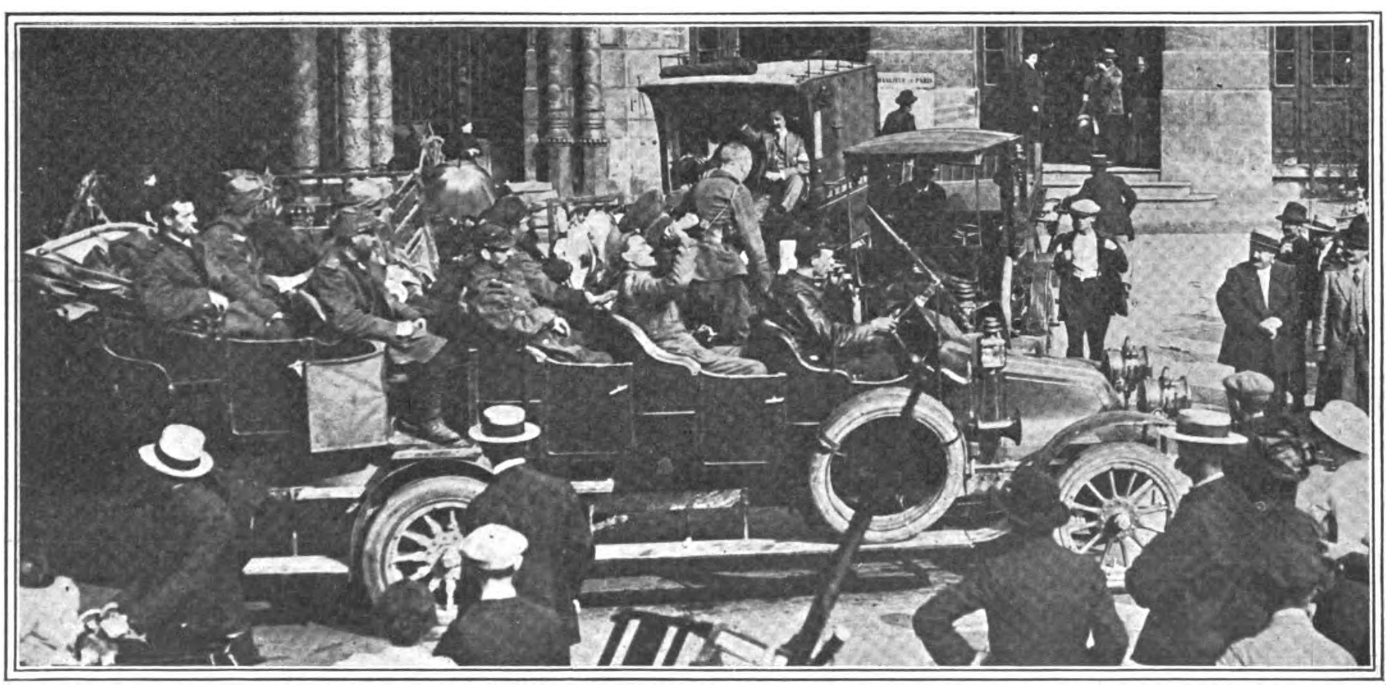
Although hastily constructed and lacking in finish, these vehicles proved invaluable to the Belgian troops. The armor plating was pitted with bullets, but not a single shot went through. When the Germans entered Brussels it was seen to what an extent they had made use of armored automobiles in all their operations. Their plan was to advance with these vehicles into districts only poorly guarded, bombard the villages, set fire to a few houses and continue leaving the peasants in a terrified condition.

Brussels had no well organized automobile service to fall back upon when her territory was invaded. The authorities therefore sent police into the streets with orders to seize all suitable cars. The passengers were turned out and the driver, if of Belgian nationality, was put under military orders. This plan worked well, for each man knew his car and could get the best possible service out of it. In other towns, where cars were requisitioned and given to military drivers much trouble followed, for it frequently happened that the drivers had no experience with this make of car and quickly had their vehicles in a broken down condition.

B. N. D. Steel Factory Wrecked

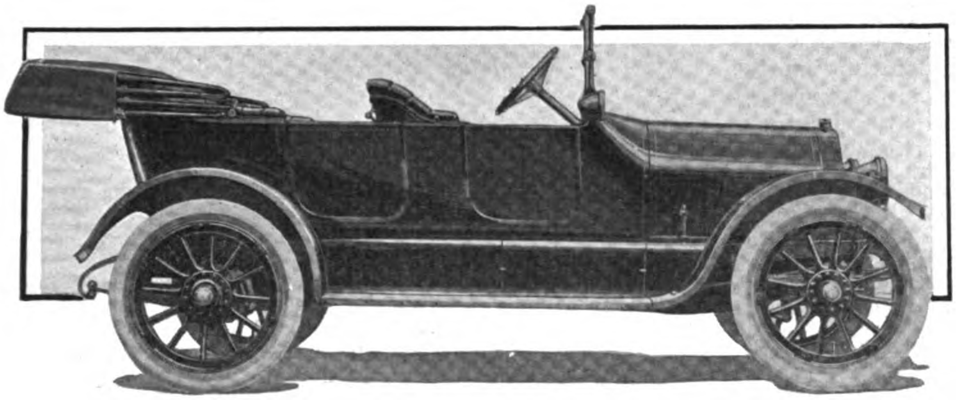
The Pipe factory, one of the most important in Belgium, has escaped damage, for it is located in the heart of the city. It is practically certain that the Derihon factory, at Liege, where the famous B. N. D. steel is produced, has been completely wrecked. This factory was situated at the foot of one of the forts on the outskirts of the city, and it was at this point that fighting was most severe. No definite news has been received as to the whereabouts of the Derihon Bros. one of whom was in active service with the Belgian troops.

It is also believed that the F. N. factory at Liege has been razed to the ground. This factory, in addition to producing automobiles and motorcycles, was the small arms works of the Belgian government. The women who work in the gunmaking departments took up arms when the men had been called away, and as these women are all excellent shots they were able to do some destructive work.



French and English wounded soldiers leaving the Gare du Nord, Paris

Overland 81, Fully Equipped, $850



Overland 81 five-passenger touring car with left drive and center control

Four Cylinder 4 by 4.5 Motor—Electric Starting and Lighting— —Left Drive—Center Control— Also Roadster and Delivery Bodies

MODEL 81 is a new Overland for next year, which sells at $850 with full equipment, including electric lighting and starting units. The same chassis with a roadster body, with the same equipment, sells at $795.

This chassis when fitted with an open express delivery car sells at $850 and with a panel delivery body at $895. These prices of delivery wagons include the electric lighting and starting equipment.

This new Model 81 is a typical Overland design in that the standard features of the Willys-Overland Co., Toledo, O., have been strictly adhered to. Except for a slight difference in bore, the engine is practically the same as that of the larger 1915 model, which made its appearance in August. The bore of model 81 is 1-8 inch less than that of the larger model. The cylinders measure 4 inches diameter and the stroke is 4 1-2 inches. The cylinders are separate castings and the same general arrangement of parts such as manifolds, accessories, valves, etc., is adhered to. Back of the motor is the standard Overland construction with the gearset forming a unit with the rear axle.

This new Overland car, selling at so low a price as $850, is the result of large-quantity production facility at the factory, which facilities have each year been added to until today the plant embraces a great area with a large array of departments in which practically every part of the car, including frames and radiator, are manufactured.

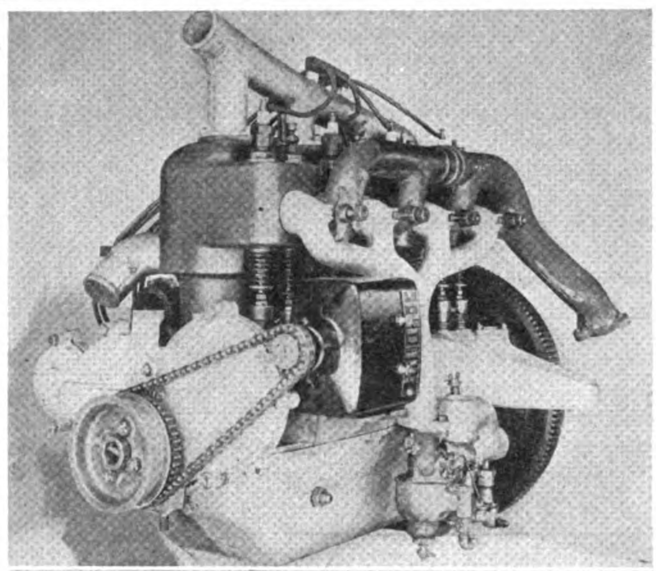
Develops 30 Horsepower

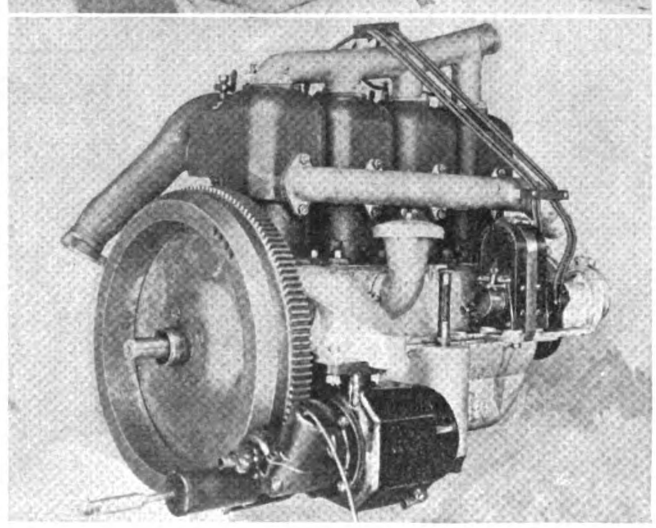
The motor in model 81, 4 by 4 1-2 inches, gives a formula rating of 25.6 horsepower, but actually develops 30 horsepower. It has a piston displacement of 227.5 cubic inches, and its stroke-bore ratio is 1.125. Like other Overland motors, thermo-syphon cooling is employed in conjunction with a cellular-type radiator affording vertical circulation. This radiator has a shell pressed from one piece of sheet steel in the company's radiator plant. With this construction the round edge appearance of the radiator is possible.

The left side of the motor is given over to the valves, the manifolds, carbureter and generator. Both intake and exhaust headers must naturally have separate openings to each of the cylinders, the exhaust pipe passing above the intake. The carbureter has a hot-air attachment. The exhaust manifold is made in two sections so that that portion serving the front two cylinders may be removed without taking off the entire manifold, or vice versa.

Valve Parts Accessible

Valves are not enclosed and present conventional appearance. A yoke construction with a bolt drawing down at its center holds down the tappet assemblies for each cylinder—





Upper—Overland model 81 motor showing mounting of the generator which is driven by a silent chain from the crankshaft. The carbureter is carried low and the motor is suspended at three points. Bottom—Right side of motor showing starter and magneto positions. Note the simple method of carrying the high-tension wires

The water pipes are without sharp bends that might pocket the water, and are of larger diameter. On this side also is a large breather and an oil level indicator intake and exhaust. This one bolt allows their removal in simple fashion. The valve mechanism of the Overland leaves nothing to be desired in the way of accessibility.

Lubrication by Splash

Lubrication is maintained by a constant level splash system with individual splash troughs under each cylinder. Into these the rod ends dip and throw the lubricant up into the cylinders and onto the bearings. The level in the troughs is maintained by a geared oil pump, and a revolving sight-feed indicator on the dash tells that the oil is circulating. The lower part of the crankcase below the troughs forms the oil reservoir into which the overflow falls ready for re-circulation after straining.

Ignition, entirely independent of the lighting and starting equipment, is provided for by a high-tension magneto located on the right forward side of the engine and driven by a shaft in connection with the timing gears.

Separate Electrical Units

As to the other electrical functions, the generation of current and the cranking are taken care of by separate units. The generator, mounted on the left front of the crankcase on a bracket attached thereto, is driven by a silent chain from a sprocket on the front end of the crankshaft and just back of the fan belt pulley. Due to the difference in size of the sprockets, the generator operates at 2.6 times crankshaft speed. It begins to charge the battery at 8 miles per hour and at 25 miles an hour is producing its full charge of 14 amperes. Due to the reversed series coil, the output does not go above this amount regardless of car speed.

The starting motor is compactly built series-wound machine operating on the battery current of 6 volts. It is located at the rear of the motor on the right, and acts directly on the flywheel, a sliding pinion on the electric motor shaft engaging with teeth cut on the rim of the flywheel when the gear latch is released and the heel button pressed down. The ratio of the electric motor speed to that of the engine is 11.1 to 1.

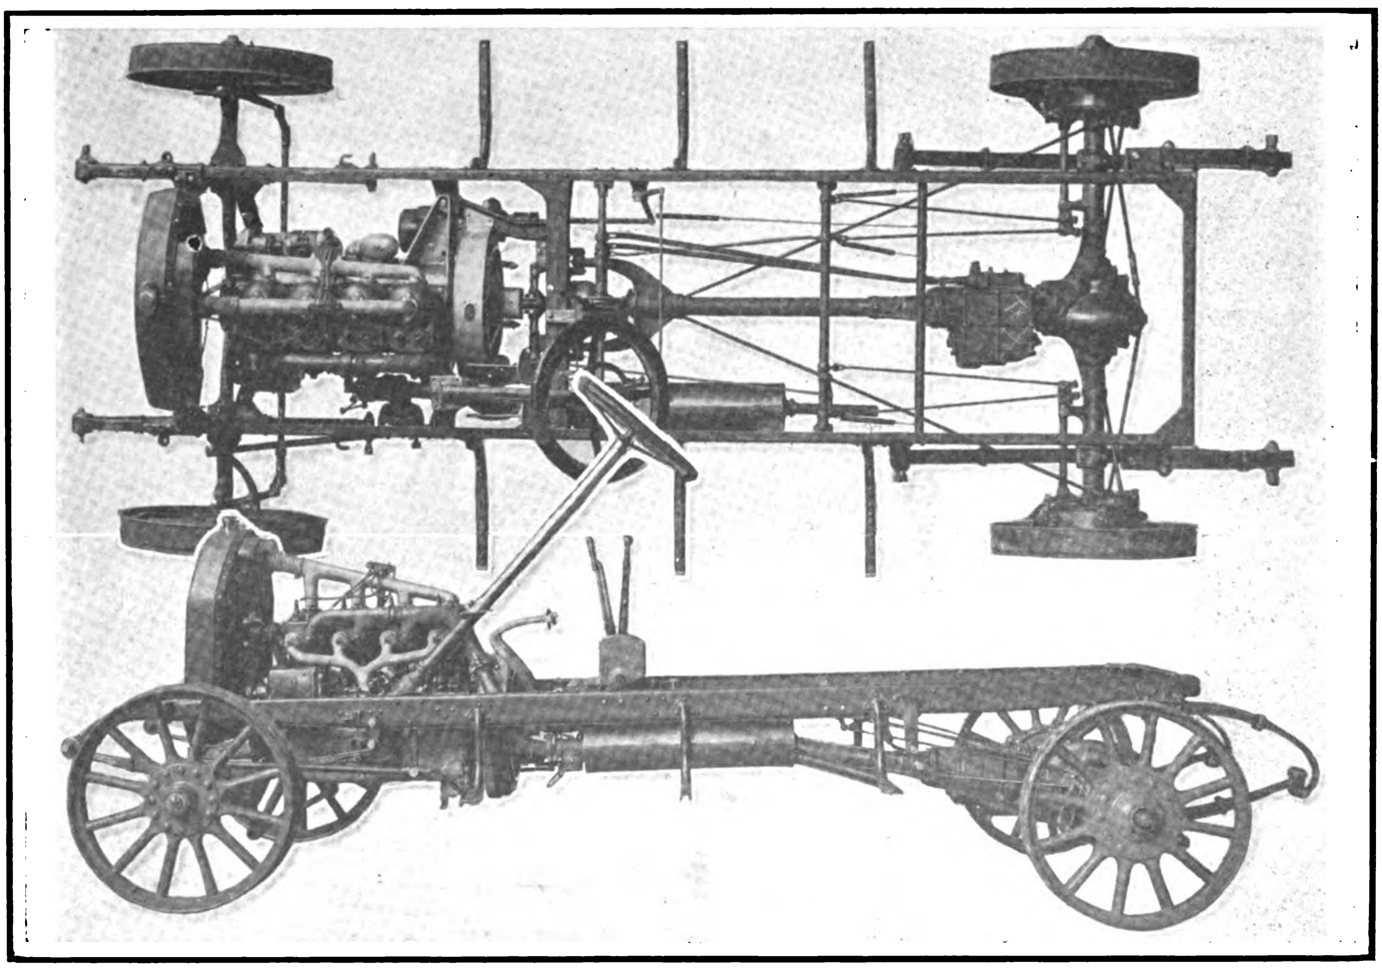
Three-Point Suspension

The motor is suspended on three points. At the rear of the crankcase and just ahead of the flywheel there is an integrally cast arm extending out to and resting upon a diagonal frame member which in turn fastens at one end to the frame side member and at the other to the main cross member back of the motor. Thus the arms do not have to be long enough to extend out to the side rails and are thus stronger. The third supporting point for the motor is at the center of the front where it rests upon a frame cross member which is bowed downward.

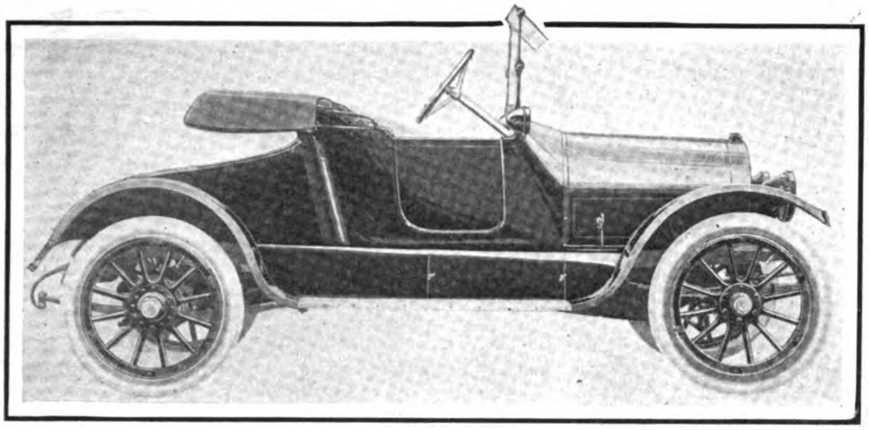
Five-Bearing Crankshaft

The crankshaft, which is carried on five main bearings in the upper half of the crankcase, is due to this number of bearings and its size, very rigid and free from vibration, a feature which the motorist today is coming to think a great deal of, for it tends to greater silence, power, flexibility and less wear. Pistons, each of which is fitted with three piston rings are secured to the connecting rods by conventional wrist-pins carried in the piston bosses.

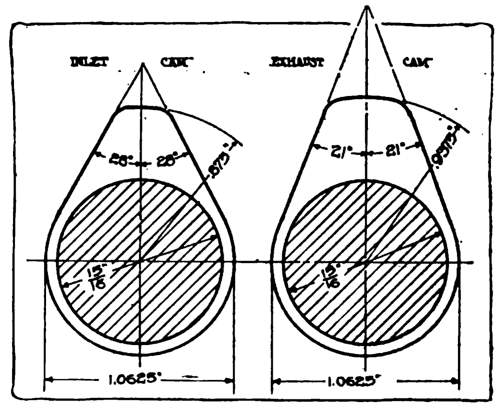
The camshaft is mounted on three bearings and like the crankshaft is drop-forged from carbon steel. The valves are made with carbon steel stems electrically welded to 3 1-2 per cent. nickel steel heads. They are of usual form and seat at 45 degrees.



Upper—Birdseye view of chassis showing straight frame members. The torque tube and axle ends are strengthened by struts. Lower—Elevation of chassis



New Overland model 81 runabout which sells for $795



Intake and exhaust cams

The principal motor dimensions follow:
Crankshaft bearings:
Front—1 1-2 by 2 1-8 inches.
Three center—1 1-2 by 2 1-8 inches.
Rear—1 1-2 by 4 inches.
Connecting-rod lower bearings: 1 1-2 by 2 1-8 inches.
Camshaft overall length—27 9-32 inches.
Camshaft bearings:
Front—15-16 by 2 1-4 inches.
Center—15-16 by 3 1-8 inches.
Rear—15-16 by 2 9-16 inches.
Valve lift—13-32 inch.
Valve diameter—1 13-16 inch.
Valve seat—1-8 inch by 45 degrees.

The cone clutch used is leather faced and acts in the flywheel in the usual way, four springs holding it in engagement. Inserted in the cone face are spring-pressed studs to augment easy action, while a clutch brake stops it from spinning when thrown out. This aids gearshifting. Back of the clutch there is a universal joint, which is on the forward end of the propeller shaft just ahead of the point where it enters the torsion tube. A substantial yoke hinging at its ends to the center frame cross member carries the front end of the tube. Diagonal radius rods run from this point to the ends of the rear axle. Thus the drive and torque are well taken care of.

Gearbox on Axle

Through flanges, the gear box bolts to the torsion tube and the axle housing. It is compactly designed and affords the usual selectively obtained three forward speeds and reverse. The gears are of nickel steel and the shafts are carried on annular ball bearings. The control levers are mounted at the center of the control shaft which is mounted just back of the center cross-member. Rods run from this control back to the gearbox and to the brakes.

The rear axle is the Overland floating type design with four differential gears; the axle shafts removable and roller bearings carry the loads with ball thrust to take the end thrust. The brakes are of ample size, the drums being 10 inches in diameter and 2 1-4 inches wide.

Springs are long and flat, which is a feature for easy riding. The rear springs are slung under the axle with swivel seats while the fronts are of the regular half-elliptic type. The dimensions are 36 and 46 inches, front and rear lengths, respectively, while all leaves are 1 3-4 inch wide.

Frame Straight

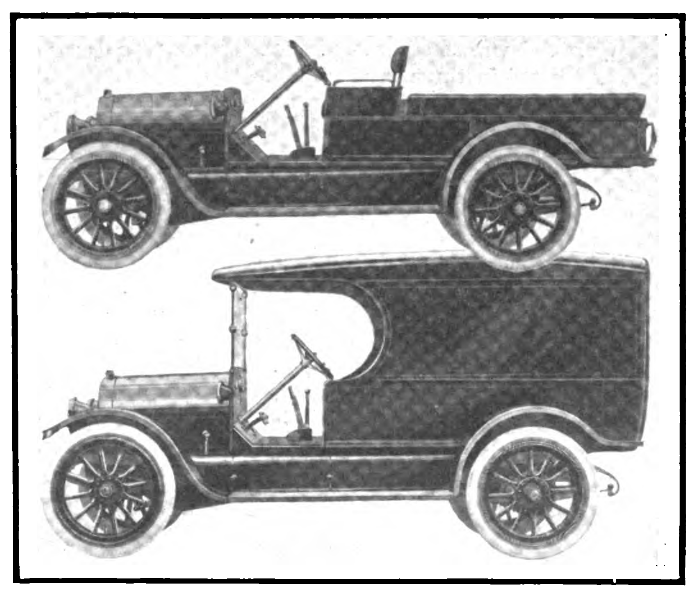
The frame makes a good manufacturing proposition, in that there is no kick up at the rear, nor is there any insweep at the front. The wheelbase is 106 inches and tread 56 inches. The car carries 33 by 4-inch quick detachable tires on demountable rims and the wheels are of wood, artillery construction. Steering is on the left.

The body is a smooth line design with steel panels and doors, and wood frame. The cowl slopes to the bonnet and the instrument board has the various gauges and speedometer conveniently grouped and lighted by a dash lamp. The doors are of the front-hinged U form and their hinges are concealed. The fenders conform closely to the curve of the wheels and running boards are clear.

Gain of $106,000 in Massachusetts Fees

BOSTON, MASS., Sept. 14—Up to September 1 Massachusetts motorists have paid into the State coffers $870,182.19 in fees and registration licenses, which is more than $106,000 in excess of the amount paid for the entire 12 months of 1913. If the present rate of registering continues the total for 1914 will be close to $1,000,000. There had been registered up to September 1 73,367 motor vehicles, which shows an increase of 23 per cent., or 13,789, over the same period in 1913, and 6,747 more vehicles than were registered during all of 1913. There are nearly 88,000 people authorized to operate motor vehicles in the Bay State now. The figures for the first eight months of 1913 and 1914 follow:

Automobiles	59,569	73,367
Motorcycles	6,578	7,553
Manufacturers and dealers	1,300	1,491
Operators	14,039	16,834
Chauffeurs	4,195	4,044
Operator renewals	34,762	43,111
Chauffeur renewals	13,542	16,165
Receipts	$719,331.09	$870,182.19

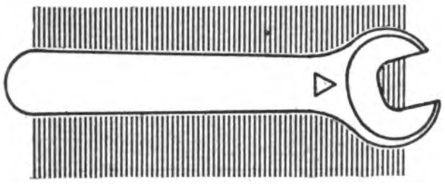


Upper—Overland 81 with open delivery body. It sells for $850
Lower—Overland 81 with closed delivery body. This sells for $895

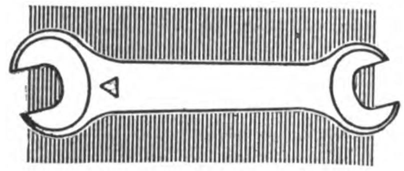
Forged Wrench Efficient and Simple

By F. C. BILLINGS

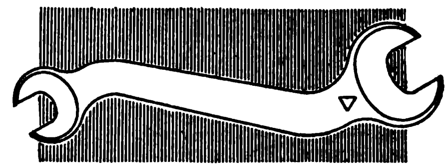
Vice-President of the Billings and Spencer Co.



Engineers' single head



Double head engineers' type



The popular S-wrench

PROBABLY the most abused, least considered and yet the most indispensable tool in the kit of the mechanic, farmer, automobilist, aviator, et cetera, ad infinitum is the wrench, the solid open-ended wrench, known to the British mechanician as the fixed spanner and known in the United States as the machinists' wrench.

Of the many kinds of wrenches, the cheapest, strongest, most efficient and most durable is the open-end wrench. This style of wrench varies in quality and price in the following order: gray iron castings, malleable iron castings, sheet steel stampings and steel drop forgings.

The drop forged wrench is superior to all in quality, strength, durability and utility. It should be made from selected .15 to .25 carbon open hearth bar steel. The bar steel is heated and the wrench formed in dies held in heavy forging hammers. After forging, the wrench passes through various operations of trimming, grinding, milling the openings to size, and not the least important is the heat treatment.

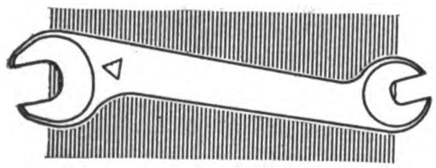
Three Grades of Wrenches

Drop forged wrenches are manufactured and listed in three grades of finish known to the trade as milled or unfinished, semi-finished and full-finished.

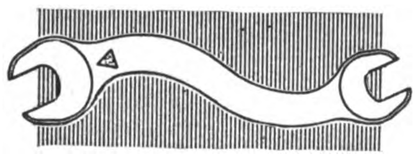
The unfinished wrench is the rough forging with openings milled to size. The semi-finished wrench is the same with the addition of heat treatment and hardening, and with the heads brightened. The full-finished wrench is polished all over before the heat treating and the hardening operations and, with brightened heads, is finally treated with a lacquer finish which acts as a rust preventive and gives the wrench an attractive appearance.

Engineers' Wrenches

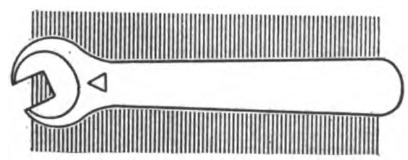
Open-end wrenches are made in a variety of styles and sizes. The style most used is the 15-degree-angle-single-and-double-end-line, also known as the engineers' line. This line was designed primarily to fit U. S. standard bolts and nuts and is also furnished with openings to fit square and hexagon head cap screws, A. L. A. M. standards, S. A. E. standards, and, for export to the British possessions, Whitworth standards, and for Europe the International standard.



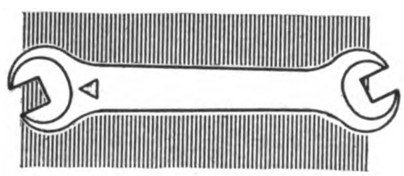
Textile wrench for mill work



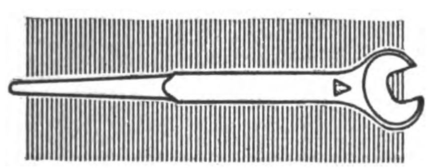
General service wrench



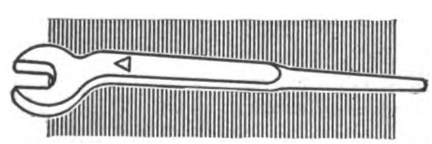
Single head set screw wrench



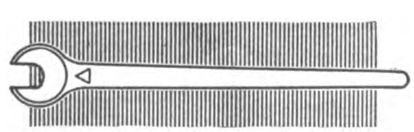
Double head set screw type



For construction work



Structural type of wrench



Single head track wrench

The term 15-degree-angle refers to the angle at which the head of the wrench is placed on the handle and has been determined to be the angle at which the utmost efficiency can be secured in confined places.

Further points considered in designing this line are the size and thickness of heads to give the required strength without unnecessary weight and the shapes and length of handles to give the necessary leverage.

Two styles of handles are used on this line of single-head wrenches: the flared handle, which is narrowest where it joins the head and widest at the end, and the taper handle which is widest where it joins the head and narrowest at the end.

The flared handle is used on wrenches up to about 14 inches in length and the taper handle on the larger sizes.

Check Nut Wrenches

Check nuts are used to prevent threaded connections from working loose on account of vibration. These check nuts are quite thin as compared with other styles of nuts; also two check nuts are often used together to further insure the fixedness of the threaded connection; therefore check nut wrenches have quite thin heads. Otherwise they are of the same general style as the engineers' or 15-degree-angle wrenches. They are made in both single and double end.

S Wrenches

S wrenches are very popular and are made with all the different standard openings. Owing to its shape, from which it derives its name, this style of wrench is used in confined places where a straight-handled wrench will not reach the nut or bolt.

The so-called textile wrenches were originally designed by a firm which manufactured looms and other textile machinery. This is a double head line with heads at an angle of 22½ degrees with the handle. The wrenches are considerably lighter than the engineers' line and with thinner heads. These wrenches are largely used in mill towns by loom fixers, etc. They are furnished with all of the standard openings.

General Service Wrenches

General service wrenches are what the name implies and were originally designed for carriage makers' use, and are popular with carriage makers, farmers, garage men, etc. They are light, handy wrenches, and owing to their lightness should not be used for severe work. This line is furnished with all the standard openings, including A. L. A. M. and S. A. E.

Set-Screw Wrenches

The tightening of set screws is one of the hardest uses to which a wrench is put, and the average wrench is not strong enough for this duty, therefore the reason for a line of single and double end set screw wrenches especially designed for this work.

Construction and Structural Wrenches

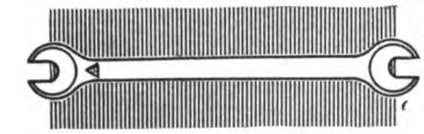
Construction and structural wrenches are especially designed for bridge and structural iron workers. Construction wrenches are made with 15 degree angle and structural wrenches are straight with an offset head. Both these lines have a round, pointed handle which is used to bring punched holes in beams into line so that a bolt or rivet can be inserted.

Track and Car Wrenches

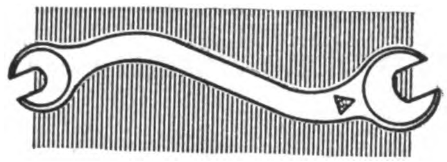
Track wrenches and car wrenches are used by railroads in the construction and maintenance of tracks and cars.

Machine and Tool Post Wrenches

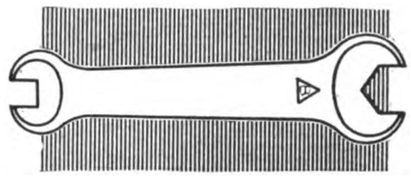
In addition to the above and in the general line of standard wrenches there are machine wrenches and tool post wrenches that are used on machine



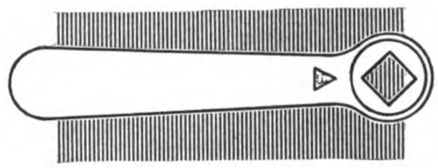
Double head track wrench



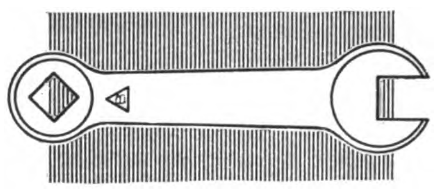
Wrench used for railroad cars



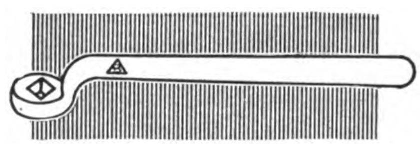
Machine wrench—double head



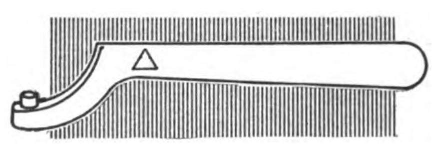
Single head tool post wrench



Double head tool post type



Chuck wrench for lathe work



Single pin type of wrench

tools; also chuck wrenches for operating lathe chucks.

The foregoing wrenches about cover the different lines of open-end standard drop forged wrenches. Other standard lines are spanner wrenches and pin wrenches. These are used for turning collars on threaded spindles.

Socket Wrenches

A very complete line of socket wrenches is now manufactured and listed, both in the T-handle and bent handle varieties. These are made for both U. S. standard hex nuts and for square nuts, cap screws and set screws.

Many of the manufacturers of drop forged wrenches are now putting up wrenches in sets contained in a canvas case or bag. These sets are made up for automobilists, farmers, loom fixers and for general purposes where wrenches are used.

Wrench Display Board

Probably one of the innovations in the matter of handling wrenches which most strongly appeals to the dealer is the arrangement of a stock of wrenches on a display board that is designed to be hung in any convenient and prominent place in the store.

In the past, when a dealer had concluded to put in a stock of drop forged wrenches and it came time to put in a stock order, as a rule he did not know what sizes, kinds or quantities to order, and was apt to ask the salesman to help him out in the matter of the initial stock order. The salesman really had no more knowledge of the dealer's requirements than the dealer himself and generally, in his desire to turn in a substantial order to the house, would stock the dealer up with what would be more or less deadwood, probably on account of locality requirements.

When the stock order arrived, a limited quantity of the smaller sizes would be put on the shelves and perhaps in the show cases, but the bulk would be stored in the basement in bins or on shelves, and in all probability a large part of that stock in the basement would not move in years.

Thinks Oversize Tires Economical for Trucks and Cars on Long Runs

The Automobile Engineers' Forum

Many Factors in Tire Wear — Trucks Most Often Overloaded and Tires Suffer from Careless Driving—Tires Age without Respect to Size

AKRON, O.—Editor THE AUTOMOBILE:—Regarding the economy and advisability of oversizing tires, there is considerable merit in both the pro and the con of the contention. While the statement that a tire would be damaged by cut or puncture, before the effects of undersizing could be appreciated, was almost an axiom as late as 2 years ago, the general improvements of highways and the general increase of engine speed in nearly every make of automobile has altered the near axiom of a new fallacy.

The touring car avoids bad roads and rough spots, considering the comfort of the passengers, if nothing else. The tire question, therefore, with pleasure cars is almost entirely one of wear and endurance. On cars of this type oversizing is unquestionably advisable, save where the car is so located that it can run only about 2 months of the year and is jacked up the other 10.

One size of tire ages just as rapidly as another and when a customer's tire trouble is chiefly due to dry and separated friction, the greater cost of an oversize tire is hardly economical.

Tire Must Keep Normal Shape

If the carcass is stronger, an oversize tire is better able to retain its normal shape under a load. The retention of this normal shape is absolutely necessary to the long life of the tire, for:—

1—Flattening out of a tire under a load offers an unnecessary amount of tread surface to the road, causing the tire to heat more and wear faster.

2—Flattening out of a tire flattens its sectional arch, destroying in great measure its ability to sustain its burden and causes the fabric to mesh or tear and blow out.

3—The flattening out of a tire requires more power to operate the car. A greater amount of gas is consumed by the engine and the gears are heated by the constant dragging.

Trucks Have Most Overloading

The greatest amount of trouble due to overloading tires is experienced by commercial vehicles. The commercial car meets with conditions radically different from those of the touring car. The principal consideration is the size of the car and its type of work.

There is first to consider the light laundry or drygoods car, on 3 and 3½-inch tires, which is required to make innumerable stops and get under way again as rapidly as possible. Such cars are in constant danger of puncturing, bruising, or tearing their tires. Their brakes are often set suddenly and skid the tire. Their engines are of a high speed type that step up from full stop to 4 or 5 miles an hour in about 30 feet. This causes a jackshaft that jerks and strains a tire or else spins it.

Oversizing on such a type of car is hardly economy. The greater tread surface offered to the road by an undersized tire gives a greater tractive power and saves the engine the jerking strain occasioned by spinning, even though it does ruin the case. There is not much danger from heating, due to the frequent stops and the fact that most of these routes are along the shaded streets of residence districts. But there is a constant danger of curb bruising, cutting in car tracks, rim cutting and punctures, and this can hardly be avoided by oversizing.

The heavier type of car, namely those on 4½ and 5-inch tires, are generally subject to long, continuous runs and their usually top-heavy loads require as stiff a side wall and tread as possible.

This type of truck is usually high geared and exerts a terrific strain on the tires in turning corners and in twisting in and out along crowded thoroughfares.

Striking the Curb Hurts Tires

Last, but not least, owing to the fact that the majority of these cars are end-doored, they invariably bang the curb in backing up for a load and here the extra ply of fabric in an oversize tire is often worth its price a hundred times.

Oversizing, therefore, is of value on trucks or cars subject to reasonably long and continuous runs, but is hardly an economy on cars that run from door to door.—RICHARD T. WALSH, Service Department, Swinehart Tire and Rubber Co.

Where Proper Inflation Fails, Oversize Tires Should Be Used

AKRON, O.—Editor THE AUTOMOBILE—The importance of keeping a pneumatic automobile tire inflated to the proper pressure, and avoiding the evil of underinflation, is something that can never be overemphasized. If less than the proper pressure be carried the weight of the car will not be properly sustained and as a consequence, there will be more or less flattening out where the tire touches the ground. This not only subjects the casing to a destructive bending action when in motion, but renders it susceptible to injury from bruises and bumps which a fully inflated tire would safely resist.

Flattened Tire Is Strained

The same condition occurs when a car with its extras is not equipped with tires large enough to properly support the load and although it be properly inflated, the weight flattens it out where it rests on the ground just as in the case of a tire large enough but not inflated to the proper pressure. The extra strain thus imposed not only breaks down the side walls but increases susceptibility to all the various forms of trouble.

In the design of a bridge where the factor of public safety is actively important, there must be no possibility of a breakdown. The strains and their combinations are carefully calculated from both theoretical and empirical data. When, in this way, it is determined that a bar ¼ inch thick would be just equal to the strain, a bar 1½ inches thick—six times the thickness actually necessary—is adopted. The extra inch and a quarter is a margin of safety which insures the structure against any unforeseen and unusual strain to which it may be subject. The lack of this margin of safety would be inimical to public welfare.

Margin of Safety Necessary

By the same token, the tire which gives good service, other things being equal, is the one which not only provides the necessary strength to resist the average strains but which also provides sufficient margin of safety also to resist the unusual extra strains which at times occur even when reasonable care is used in driving.

Proper attention to inflation will usually insure good service. For the man who exercises care in this particular but who is still unrewarded with the good service usually returned by this precaution, the solution lies in the use of the oversize tire—the largest tire that fits each rim. For every standard size of rim, there are two sizes of tire which fit. For example, a 34 by 4 rim carries a 34 by 4 tire. Should the 34 by 4 tire, after the car has been equipped with its extras, prove inadequate for the support of the load, the 35 by 4½ tire which also fits the 34 by 4 rim and is the regular oversize for the 34 by 4, is the proper size to insure satisfactory service. Also the 33 by 4 is the regular oversize for the 32 by 3½.

Oversize Takes the Same Tube

Usually, it is by experience that the motorist discovers he has equipped his car with tires that are too small. He then desires to change to the regular oversize tire for his rims. For making this change, the manufacturer has provided every convenience. Not only does the oversize fit the rim as perfectly as the regular size, but it also takes the same tube. Tubes, like rims, are now made interchangeable. Consequently the change over to the oversize will not require any changes or additions as to the tube equipment.

30 Per Cent. More Capacity

The oversize tire contains between 30 and 40 per cent. more air capacity than the regular size. This extra capacity makes possible not only a more effective air cushion to sustain the weight imposed, but higher resilience as well. An oversize tire naturally costs more than one of the regular size because it is larger. Its more effective air cushion, however, as well as the better distribution of road wear because of its extra width, insures still greater mileage in proportion to the initial cost. And so its use decreases the cost per mile; and cost per mile, rather than cost per tire, is the ultimate test of economy.—F. A. HENDERSON, Manager Adjusting Department, Goodyear Tire and Rubber Co.

Decisions of the Courts—Motorist Recovers Damages

By GEORGE F. KAISER

NEW YORK Court says that when a motorist has an unobstructed view along a street containing car tracks for 200 feet and he starts across without again looking for a trolley, he is not negligent as a matter of law since no car could then be in a dangerous proximity unless it was being run at an unlawful speed.

A motorist's car was on the west side of Broadway, south of 11th street. While attempting to turn to the north on the east side of Broadway his car was struck by a trolley. Before starting his motor he had an unobstructed view for 200 feet and he saw no car until he was in the middle of the track. A trolley came along at the rate of 30 miles an hour and before the motorist had time to reverse the automobile it was hit by the trolley. The motorist sued the trolley company and the Court said that where a trolley proceeds at an unusual rate of speed after an automobile is in clear view, the trolley company is guilty of negligence and must stand for damages caused by a collision.—*Brandt vs. N. Y. Railways Co.*, 147 *N. Y. Supp.*, 17.

Motorist vs. Garage Man

Michigan Court holds that a garage keeper's lien can be assigned to another person when he sells his business, and that the lien may be held to include freight charges which he has paid and an extra tire which he has furnished.

A motorist sued a garage keeper to recover his automobile which was held by right of lien by the latter. He had made arrangements with the garage keeper's predecessor to the effect that he would ship it to Muskegon where it was to be received and repaired. The garage keeper's predecessor paid $33.60 freight charges and furnished an extra tire for which he charged $50.75. Some time after a settlement was made and $75 was paid on account and it was agreed that the balance of $171.60 was to be paid before the car was turned over to the owner. After that the garage keeper went out of business and assigned his lien and claim for repairs. The motorist demanded the car without offering to pay his bill and when it was refused him he sued. The Court ruled that the garage man's successor had a right to keep it until the bill was paid.—*Gardner vs. LeFevre*, 146 *N. W.* (*Michigan*), 163.

Car Collides with Trolley

Court says that when accidents occur between a trolley car and an automobile, unless explanation is given by the trolley company, the fact of the accident is evidence of the trolley company's negligence.

In this case an electric car was coming south down grade at the rate of about 40 to 50 miles per hour, swaying from side to side. Plaintiff was going north on the same road, using reasonable care. The small wheel at the top of the trolley pole left the wire when the car was about 400 feet from the automobile. The trolley pole broke off and fell against the left forward wheel of the automobile, causing it to turn to the right toward an embankment. The motorist expected the car to turn turtle and he jumped out and was injured. He sued the trolley company and recovered judgment for his injuries, the Court holding that in a case like this, unless the trolley company could give some good explanation, the fact that the accident happened showed that it was guilty of negligence.—*Hull vs. Berkshire Street R. R. Co.* 104 *N. E.* (*Massachusetts*) 747.

F. C. Billings Wrote Article on Wrenches

NEW YORK CITY, Sept. 11—Through an error made in correcting page 485 of THE AUTOMOBILE for September 10 before going to press, the signature of F. C. Billings, of the Billings and Spencer Co., Hartford, Conn., was omitted from the communication prepared by him and appearing in the Engineers' Forum under the heading "In Ordering Wrenches Mention Number and Style of Finish."

Sand Blast Has Variety of Uses

From a Paper Read by H. D. Gates Before a Meeting of Associated Foundry Foremen of New York City and Vicinity

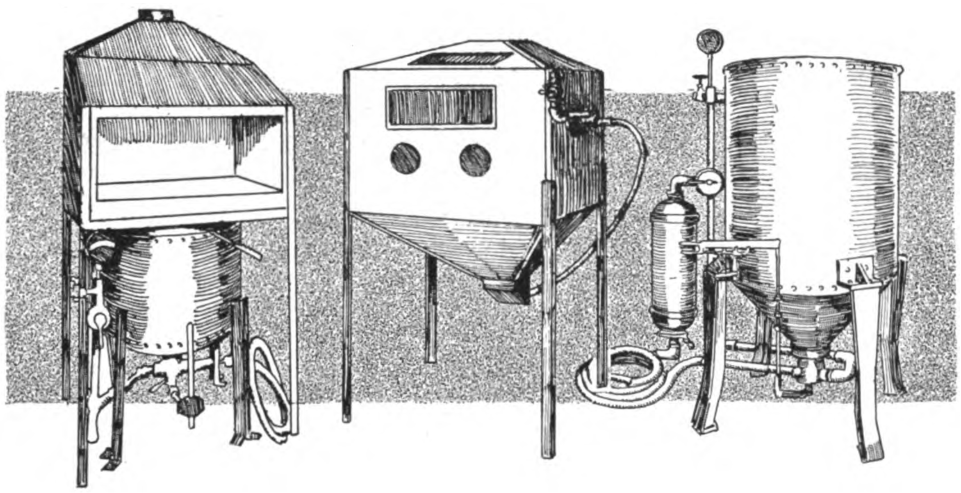

Fig. 1—Left—Combined pressure blast and cabinet. Fig. 2—Center—Continuous speed sand blast cabinet. Fig. 3—Right—Hose type pressure blast

WHILE the sand blast had its origin in the foundry for the cleaning of castings, its many advantages for cleaning or surfacing in all branches of metal working has given it a much wider use. Uncle Sam even demanded that the gates of the Gatun Locks of the Panama Canal be sand blasted before painting. Makers of automobile bodies in steel and aluminum are surfacing them before painting. With the increase in the use of the sand blast it is time to consider its economy.

The Purchaser's Problems

There is no question but there are today many sand blast machines and installations in use which are a loss to the user. Before purchasing a sand blast, it is first necessary to consider the material to be cleaned, what will be its average shape, size and weight and how many will be produced in a day. These and several other problems must be solved before the sand blast purchaser can determine if it is to be economical. If the work will not be uniform and will be in a wide variety of sizes and shapes, it will be impossible to use any but the old stand-by, the hose type of machine. This will clean everything and anything, though not always with the best economy.

Sizes of Pieces an Important Factor

Assuming, however, for the moment that the volume of the different classes of work is sufficient to warrant the use of an automatic machine, there are in general, two types for selection. For small work, the barrel type of machine shown in Fig. 5 will be unquestionably the most economical. The air volume required will, of course, be governed by the number and size of the nozzles and actual comparison of cleaning time with different size nozzles is the only way to determine the most economical for various classes of work. A single nozzle in larger size, of right design, construction and location, giving correct application of the sand stream to the work, will be found more economical in air consumption and power cost than multiple nozzles of smaller sizes.

Pieces too large for successful barreling but that will still permit of automatic handling, will be cleaned with least labor, on the round and reciprocating type table machines, of the type shown in Fig. 4. If, however, the pieces are of such shape or design as to demand constant labor in turning them to bring all surfaces under the action of the nozzle, the question of economy under these conditions requires the closest consideration before selecting this type of machine for varied work. On certain classes of material it is ideal.

Another consideration is that in many plants while the character of the work may be such as to be ideally handled by one of the different types of automatic machines, the daily volume may be so small that the unit cost of the automatic may put it out of the question. To meet such a condition, the small inclosed cabinet type of machine giving a continuous speed such as is shown in Fig. 1 will give a very satisfactory equipment.

The combination pressure blast and cabinet as illustrated in Fig. 2, also offers at small cost a highly efficient equipment for small volume work of a varied character. With this outfit the work can be accomplished in a practically closed cabinet while the outfit is still available for heavier pieces on the bench or floor as desired.

The Hose Type of Machine

Should the work of a particular plant not fall under any of the above heads, there remains one outfit that can take care of any kind of work even though at times a loss of economy on some portion of the output will result from its use. This is the hose type of machine shown in Fig. 3. This kind of machine is designed for the hardest kind of service, being able to clean metal and displace sand, rust or scale, some of

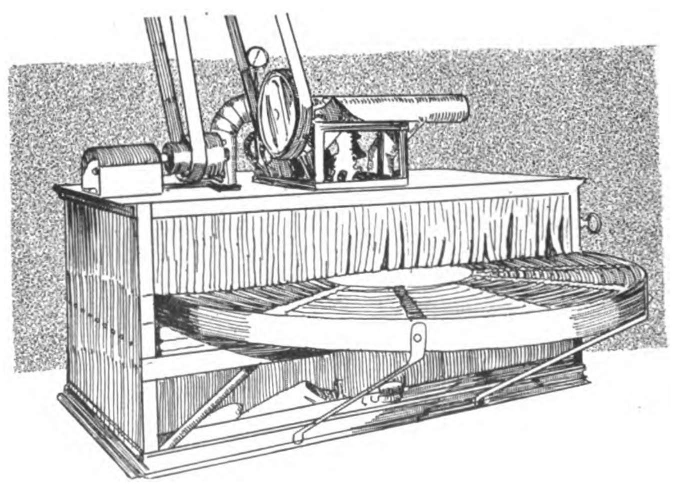

Fig. 4—Revolving table type sand blasting machine

which has fused and become almost as hard as the metal itself. The selection of this type of machine, unlike the automatics, should be made with reference to the nozzle equipment to be used. For instance, under 80 pounds pressure a 3/16 inch nozzle permits 48 cubic feet of free air to flow through per minute and discharges approximately 500 pounds of sand an hour. The air flowing through a ¼ inch nozzle is 85 cubic feet per minute and the discharge is approximately 900 pounds of sand in an hour.

Ample Air Pressure Needed

After the engineering department has calculated the type and size of the equipment necessary, the next problem to be undertaken is the question of air volume and pressure requirements. If the plant is without air, compressor equipment must be installed. In this, it must be remembered that it will be a mistake to buy a compressor adapted to barely meet immediate needs. Fully 90 per cent. of the foundries today are complaining of lack of compressed air capacity, and this is due to the constant increased demands which are made on the air plant once it is in operation. The greater first cost of an air compressor of large volume over the same type of small capacity is so comparatively slight that the provision of ample air to permit use of proper equipment for cleaning at the lowest cost per ton is undoubtedly advisable in the long run.

Undoubtedly, the satisfactory working pressure is the most mooted question among sand blast manufacturers today. There is one answer to the question, however, on which all agree and that is the pressure which is best is that which does the work cheapest. To determine this, it is of course necessary to know the exact purposes for which the blast will be used. If it is required only to remove the loose sand from a casting, a working pressure under 30 pounds will undoubtedly be successful even on iron and steel and would provide a surface suitable for painting. If, however, the pieces are to be machined, every particle of the fused sand must be taken off to expose the pure metal to the action of a cutting tool. On steel, up to 90 pounds will be required for most economical cleaning. Between these two extremes, the correct pressure must be determined.

In the test made by Prof. T. Magruder covered in a paper recently read before the American Society of Mechanical Engineers, it was shown that the time required to remove 1 pound of metal from a cast iron bar at 20 pounds pressure was 3.55 hours; at 30 pounds, 2.77 hours; at 40 pounds, 2.13 hours; at 50 pounds, 1.52 hours; at 60 pounds, 1.07 hours, and at 70 pounds, .82 hour.

The abrasive used is another factor in the economy of the

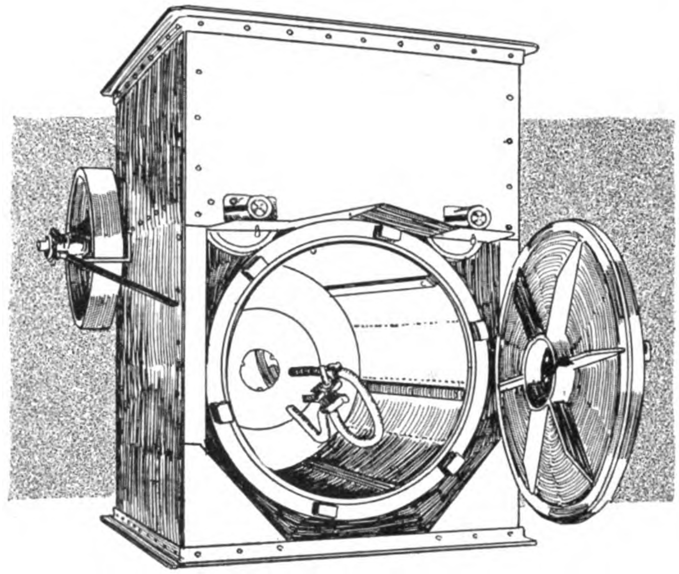

Fig. 5—Barrel type of sand blasting machine which is suitable for miscellaneous jobs

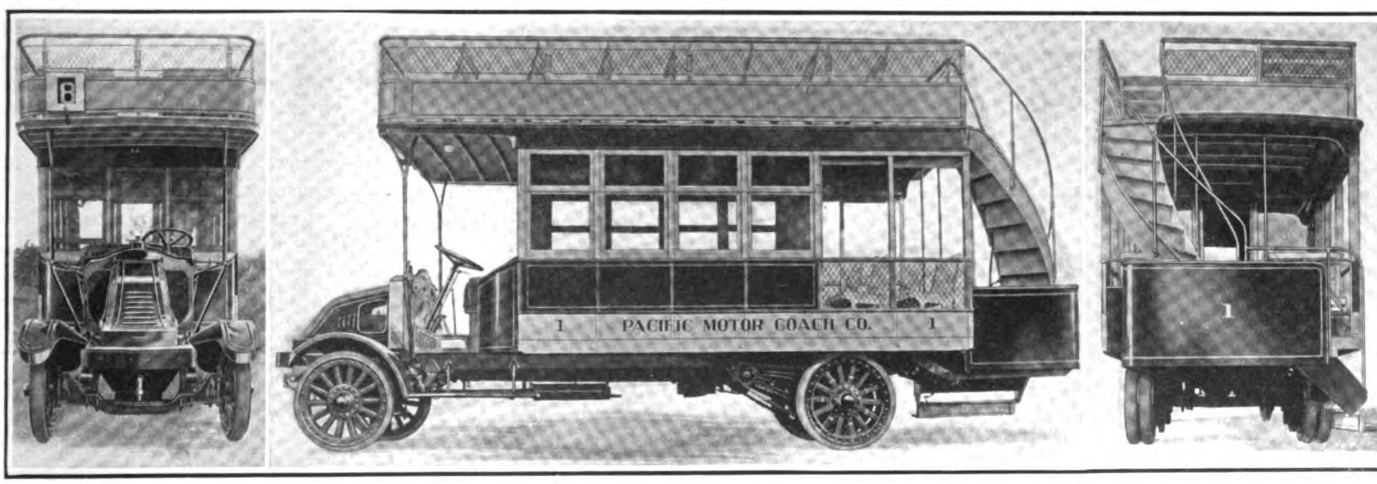
blast. Tests show that lead shot and grit have approximately sixty times the life of sand. In an instance of use of grit with a hose machine, a steel foundry reports a loss of but 10 per cent. out of 3 tons at the end of 1 month. When sand was used, the daily loss by disintegration was 25 per cent. In another foundry the cleaning time required was reduced 20 per cent. by using shot. This seems logical as the metal abrasives have two and a half times the specific gravity of sand.

Records kept for a period of 6 months in this plant showed that with this same apparatus and under the same conditions the 1 pound of shot was equal to 20 pounds of fine silica sand.

Care of the Machine

Care of the machine is the last but far from the least important advice given to the user of the sand blast. Methods of handling and screening the sand should be determined not only by the cost of power requirements, but by the efficiency of separation demanded. Some idea may be obtained of the relative value of different installation, from the fact that one steel concern using a plant provided with adequate ventilation with the abrasive handled, screened and cleaned automatically, was able to increase the output of its sand blast from 15 tons in 10 hours to upward of 18 tons in 5 hours. Routing of the material and handling methods are other items.



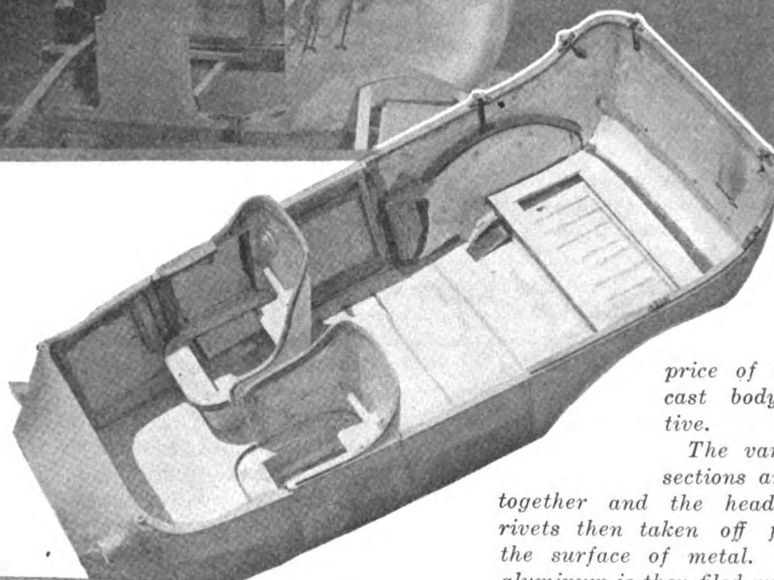
Front, side and rear views of one of the 3.5 ton Kelly Springfield buses to be used in Los Angeles, Cal. One hundred and four of these buses have been ordered by the Pacific Motor Coach Co., Los Angeles, Cal., and are to be operated in and around the city. The bodies were built by the St. Louis Car Co., St. Louis, Mo., and are unusually capacious. Seats for fifty-four passengers are provided—thirty on the upper deck and twenty-four on the lower, eight of these being on the open portion at the rear. A speed of 20 miles per hour can be maintained

Cast Aluminum Shells for Pierce-Arrow Bodies

OFFERING a choice of fifty-four body styles, the Pierce-Arrow Motor Car Co., of Buffalo, N. Y., has set itself a task in body building that requires the efforts of special machinery and an immense floor area especially devoted to this branch of automobile manufacture.

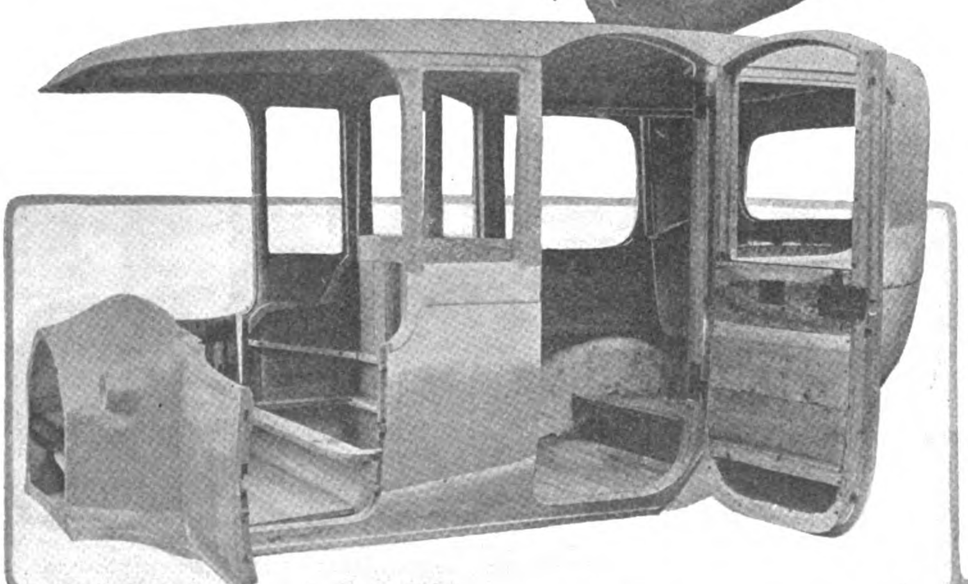
The Pierce bodies are distinctive in that they are made from cast aluminum instead of from the sheet aluminum generally employed by body builders when using the light metal for their carriage work. The company believes that outside of securing a rigid piece of work by the use of the cast metal there is a further advantage in ultimate economy by the use of standard moulds.

In the accompanying illustrations are shown the shop in which the body work is carried on and examples of open and closed car practice in cast aluminum. In practically every case the cast metal is used in preference to the sheet construction by the Pierce company. There is an exception, however, to this and that is where bodies of such individual design are ordered that the cost of moulds and pattern work would make the price of the single cast body prohibitive.



The various cast sections are riveted together and the heads of the rivets then taken off flush with the surface of metal. The cast aluminum is then filed and scraped, giving a smooth working surface for the painting which follows. When all the parts are joined together the aluminum shell is sent to the wood workers to receive its backing of ash.

It is stated that these bodies are lighter and more serviceable than sheet metal ones. They are rigid and do not drum from vibration, or warp or buckle from extreme changes of temperature. Their rigidity is also a great protection to the finish as there is no danger of the paint cracking. Another feature is that the mouldings are integral.



The Ideal American Six

Should Have Efficient 4 by 6-inch Motor, Flywheel in Front and Expanding Brakes, Says A. Ludlow Clayden, M. I. A. E., in Paper Presented To S. A. E. at Cape May

At the present time the position of the six-cylinder car in Europe forms a very interesting study. It is doubtful whether anyone can forecast its future. There was a day when high power was obtainable only from a large car by means of using six cylinders. But at the present time, methods of manufacture and principles of design have undergone so much alteration that numerous high-powered four-cylinder cars, which are quite as smooth and pleasant to handle as the best six-cylinders, are coming on the market. Further, there are a number of difficulties peculiar to the six-cylinder construction. The vexed question of six-cylinder carburetion has never been settled. The difficulty of eliminating periodic vibrations with the necessarily long crankshaft still remains pronounced. Also, probably owing to piston friction principally, the six-cylinder engine is invariably less efficient than a four-cylinder of equally good construction—efficient, that is to say, in the power to volume ratio. This means that for a given power a six-cylinder car must necessarily be considerably heavier than a four-cylinder. Add to this increased cost for a given power, decrease of available body space for a given wheelbase, or greater length and therefore cumbersomeness necessary to carry a bigger body, and most of the disadvantages of the six-cylinder car have been summed up. On the other hand, there are a few six-cylinder cars which possess greater smoothness than has yet been attained with any four-cylinder, owing to the undeniably better torque, but none of these cars is efficient. They are cars which, while suited excellently to bear elaborate carriage work and provide luxurious travel at moderately high rates of speed, are seldom found in the possession of men who drive themselves or take a great interest in the mechanism. From an advertising point of view the six-cylinder car appears to have been made the only possible thing for America. In Europe the six-cylinder argument is practically dead.

Sunbeam—Most Efficient

It is, however, possible that the present position of the six-cylinder car in Europe is misleading because no effort has been given to the production of a really efficient six-cylinder, except by the Sunbeam company; the 30-horsepower Sunbeam holds records which leave no doubt whatever concerning its efficiency. The method followed by such concerns as the Sunbeam company is, first, to produce highly efficient cars and then obtain quietness, etc., without depreciating the efficiency. In this the Sunbeam and Vauxhall companies in particular have been remarkably successful. The Sunbeam is, of course, a small six-cylinder, but there seems to be no reason why the same methods should not be applied to a larger engine.

In making a new car for England or the Continent it would undoubtedly be far better to specialize on a highly efficient four-cylinder type and leave the six-cylinder entirely alone. On the other hand, it seems that for a new American car the so far untried scheme is the production of a highly efficient six-cylinder. The specification hereunder is a suggestion for the main characteristics of such a chassis.

Should Have 4 by 6 Motor

The dimensions should be certainly not more than 4-inch bore by 6-inch stroke and there would be several advantages in adopting 3½-inch bore by 5⅛-inch stroke; this latter size would be capable of giving as much power as the largest American six-cylinder engines if the engine were made in accordance with European principles. The advantages of the smaller dimensions would be less weight, lower cost, greater ease in eliminating vibration and less overall length.

The cylinders should be cast in threes with the valves all on the right-hand side. The three-cylinder blocks are quite handleable by one man; can be rigged in position quickly and easily; are not so likely to be bad castings owing to having less complication than a block of six; need not actually require more machining if care be taken in the design; and, finally, are much easier to remove and replace. When four-cylinder blocks were first introduced there was much complaint in certain quarters that private owners would find them very awkward to take off, and undoubtedly there was something in the objection. A six-cylinder block needs very elaborate tackle and several men to remove it from and replace it on the crankcase for cleaning with the pistons in position. Of course, this is not an objection that the ordinary buyer thinks very much of until he has to take the engine down, but when he does he never forgets it. Also, in my opinion, a six-cylinder block looks very heavy and rather clumsy. However, this last is not a point of great importance.

Generous Water-Jacketing

The water-jacketing should be sufficiently generous to enable thermo-syphon cooling to be satisfactory with an atmospheric temperature of 80 degrees Fahrenheit in ordinary country. In the cylinder blocks the passages to the intake should be cored and carried through the water-jacket to the opposite side to the valves, bringing the carbureter on the left-hand side. Between the carbureter and the cylinder castings the shortest possible pipe should be used and this also should be jacketed in a manner ensuring ample circulation of hot water. Although the word pipe has been used it is better to employ a box big enough to contain one or more cylinder charges, or else to use a circular loop pipe, as has been illustrated frequently on various racing engines, and as is used by the Austin company notably. It will probably be necessary to experiment with different inlet-pipe arrangements, as different engines do not appear to be suited by precisely the same design.

Returning to the cylinder castings, these would each have a water inlet at the bottom on the same side as the carbureter. There would be the usual cast dome for a head, and in addition the Napier practice should be followed of taking two pipes from the jacket immediately adjacent to the valve-pockets, joining these and leading them up to the radiator separately from the main outlet. This has been found to make a very great difference in engines used in mountainous districts, as it prevents entirely the otherwise always-present danger of formation of small pockets of steam in corners of the valve-jackets, it being almost impossible to cast cylinders without risk of a few traps of this nature.

The crankshaft should have seven bearings because, although it is possible to make a fairly satisfactory engine with a smaller number, the best possible running cannot be obtained unless the supports for the shaft possess the maximum of rigidity and this can only be the case with seven bearings. The diameter should be not less than 2½ inches, this applying to both the main journals and the crankpins, while the webs should be proportionally stiff. Weight should not be spared in the crankcase, as the success, or non-success, of the six-cylinder engine depends almost entirely on the absolute rigidity of this portion. Very stiff webbing to support all the bearings is therefore recommended, and the case itself should be distinctly on the thick side. Distribution gearing should be by inverted-tooth chain. A chain 3 inches wide is recommended; 2½ inches might be regarded as the minimum. There are various methods of adjustment, and adjustment is deemed to be essential, not for the use of the owner of the car, but for convenience in manufacture. There would be, of course, a crankshaft pinion, the camshaft wheel, and at least one other. Whether this should drive the water pump and magneto direct or whether the third pinion should be made in one piece with a skew gear driving a cross-shaft for these two accessories, would depend upon the general layout decided upon. If it is possible to dispense with the cross-shaft a certain amount of manufacturing cost is, of course, avoided. On the other hand, usually with large engines the magneto and the pump are brought into the most satisfactory and most accessible position by the use of a cross-shaft, more especially when it is necessary to keep the magneto high. The pump might also be inserted directly in the cylinder casting by leaving the front end of the cylinder open and bolting on a bronze or aluminum casting carrying the pump and fan. This would add a facing operation, but I believe it would save in the long run, as the machining of the pump chamber and the bearings for the fan can be carried out far more expeditiously on a small piece than on the whole cylinder block.

Exhaust Header Separate

The exhaust branch should be a separate casting provided with one expansion joint between the two cylinder-blocks, and it should be kept high, so as to interfere in no way with the accessibility of the valves. Many European makers have made experimental designs in which the exhaust manifold was part of the casting. They have, however, always returned to the separate branch, which I think may be taken as sufficient evidence that the cast-in branch is not satisfactory. Supposing it is water-cooled, it is necessary to make it very big externally and also to increase considerably the amount of water carried. If, on the other hand, it is not water-cooled, it becomes much hotter than any other part of the casting; being hotter it is bound to expand and by expanding it cannot help distorting the cylinders. Even though this distortion be slight it is sufficient to increase piston friction and eventually bring about uneven cylinder wear. Further, in order to make the engine thoroughly efficient (and in my view an engine which is not thoroughly efficient is not worth introducing as a newcomer on an already well-stocked market), it is essential that the inside of both the exhaust and inlet pipes be as smooth as possible, as the resistance offered by roughness of surface is a great deal more than would ordinarily be expected. Owing to the rather complicated nature of the core it is impossible to get anything like a smooth interior with a one-piece cylinder and exhaust branch. Of course, foundry practice has improved enormously, but I am inclined to believe that there is a tendency to put too much on the foundry. Thus, in a six-cylinder block, owing to the large amount of metal to be poured, and the considerable contraction, it is possible for quite grave inaccuracies in wall thickness to occur which cannot be checked except by cutting up a casting and, of course, bad castings are sure to be those which one does not cut up.

Valves Enclosed

The valves will, of course, be enclosed under the usual cover-plates, but the tappets should be mounted in the cylinder foot. The tappets ought, in fact, to be situated in a shallow trough formed in the casting; that is to say, with the cover-plate removed there should be still left a sufficiently deep chamber around the tappets to contain oil which is bound to be exuded from the tappets. Tappets can be made without rollers, but to the detriment of cam durability, and to a certain extent to the detriment of silence. I do not quite see why this should be so, but undoubtedly it is true that the roller helps to keep down noise. It is advantageous to work the tappets in the nearest possible approach to an oil bath, and the arrangement suggested, although not easy to describe in words, is very simple on paper. The ends of the cover-plates should be curved, instead of using a flat plate butting against the end-pieces made with the cylinder casting, because these solid end-pieces render the valves at each end of a cylinder block extremely inaccessible. The curving adds a little to the cost but is certainly worthy.

The camshaft should be of a diameter corresponding proportionally to that of the crankshaft, and cams of the largest possible diameter which can be accommodated should be employed, partly for the sake of durability, but more for the sake of getting the desired valve diagram as nearly as possible. Valves should be not less than 2⅛ inches diameter.

Oil Ducts in Crankshafts

For lubricating arrangements the crankshaft should be drilled and oil supplied to each main bearing at about 30 pounds per square inch pressure. The oil would pass through the shaft to the big ends and no special means need be taken for lubricating the piston-pins or the cylinders. To prevent the access of too much oil to the cylinders the crankcase should be made with a false top. Immediately beneath each cylinder the only connection with the crankcase should consist of the narrowest slot through which it is possible to insert the connecting-rod, but the baffle-plates should not close the bottom of each cylinder individually. A method which has been employed very successfully is to extend the crankcase upwards above the baffles, which are cast in one piece with it, so that the cylinders stand open to a shallow chamber—say one inch deep—running the whole length of the crankcase and separated from the crankshaft by the thin web with the necessary six connecting-rod slats. This longitudinal chamber allows the air displaced by the descending pistons to travel along and ascend under the other three without passage through the oil-laden atmosphere of the crankcase proper. It has been found that ample lubrication is obtained when using high-pressure oil-feed, and with this scheme smoking troubles are overcome. In order to complete discussion of the system of lubrication it is necessary to anticipate a little.

Flywheel in Front

The suggested design includes a recommendation that the flywheel be placed at the front end of the motor instead of at the rear, as usual. The three lowest points in a chassis are the front axle, rear axle and flywheel, and it is easy to see that if there is a hump in the road of wave formation it will be easy for the hump to clear both the front and rear axles and yet strike the flywheel, owing to both axles being lower than normal just at the instant that the flywheel is over the hump. With the flywheel at the front end it would be protected by the front axle and over anything which the front axle would pass the flywheel would be carried also. Another conspicuous advantage, though not so important as the one just mentioned, is that consequent upon the fact that with a unit system for the engine and gear-box the necessary enlargement of the casing around the flywheel is a source of considerable weakness, or, looked at from the other point of view, the necessary enlargement calls for a very great increase of weight in order to get sufficient strength. A smaller casting without the flywheel pit is cheaper in first cost and easier to machine. The arrangement also has several advantages when the fitting of an electric motor-starter has to be considered, but these need not be gone into in detail at the moment.

Returning, therefore, to the lubrication system, the deep end of the crankcase sump obviously ought to be at the forward end as close as possible to the flywheel; otherwise the principal advantage of placing the latter at the front end is nullified. There is, however, a difficulty in that the oil supply to the pump needs to be most certain while ascending a grade. It is possible that this difficulty is not so serious as it appears, but to decide it definitely without knowing the actual clearances and without setting out the design on paper with some degree of accuracy, is almost impossible. Assuming that there is difficulty, the best way of avoiding it would probably be to adopt the system employed on the six-cylinder Wolseley cars. Here there is practically no sump, the crankcase being quite shallow, sloping downwards slightly from each end to the center. Oil is withdrawn from the crankcase by a gear-pump and supplied to a box which takes the place of the sump and is in one piece with the crankcase and high up on the side. This suction pump is of large dimensions but of quite ordinary design and appears to be in every way satisfactory. From this box on the side of the crankcase—which is large enough to contain all the oil in circulation—the forced feeds to the bearings are supplied by a separate and smaller pump. Failure of the suction pump would result in the flooding of the crankcase which would be announced by smoke, and failure of the supply pump would, of course, be shown by the indicator on the dashboard. The extra pump, however, introduces no extra risk and merely adds a little to the cost. The operation of emptying the system, washing out the oil box and so on, is facilitated a little by the higher placing, and the filters likewise become more accessible. For the suction pump a gear pattern is probably the best, but it has a disadvantage for forced feeding in that the output is not easy to control, appearing to bear no very direct relation to the speed. For the Vauxhall cars, including the racing machines, piston pumps have always been used for the oil, and it is doubtful whether this type of pump can possibly be improved upon for any purpose. It is not expensive to make and is easy to set to give the desired feed.

Babbitt Bearings Used

Having discussed the lubrication system it is perhaps worth while to add a word concerning the bearings, which should be of babbitt metal and might be die-cast. One point, however, is essential and that is that the crankshaft should be fitted to these bearings by thoroughly efficient hand-scraping. For six-cylinder work the reaming system *could* be made to serve, but it is not possible to obtain really first-class results from it.

As to the piston, these would preferably be of cast iron with the pins oscillating in the small ends of the connecting-rods, for which latter there is nothing practically better than a good drop forging. Phosphor-bronze bushes on the hardest possible steel piston-pins give the most satisfactory results. For the other bearings the exact nature of the white metal employed would of necessity depend upon the nature of the steel used for the crankshaft. For a six-cylinder crank it is probably worth while to machine all the webs, especially in a seven-bearing crank whereof the clearances must of necessity be somewhat small. It is not, however, necessary that the finish on the webs be of a very high order, because it is regarded as essential that the crank shall be balanced on a running balance machine, and this naturally applies to the flywheel as well.

Clutch and Gear-Box

Having the flywheel at the front end of the motor makes possible a single casting or a single pair of castings (the top half and bottom half) for the crankcase and gear-box. It would, however, probably be more convenient to make a separate piece of the gear-box and the clutch-box. This could be decided definitely only after laying out the design on paper. A lengthy experience of clutches of every kind has led to the conclusion that the dry-plate clutch, in which one surface is steel and the other woven wire and asbestos compound, is the most satisfactory for cars of high power. The number of plates depends upon the diameter and the engine power, and can be decided on by experience. For mounting the clutch there would be an extension of the crankshaft and the shaft carrying the striking gear would preferably be placed beneath the center rather than above it. Such positioning enables long pedals to be used, giving big leverage, while it also clears the clutch completely from above and makes adjustments readily accessible.

It is assumed that the gear-box and crankcase would be bored after being bolted together, and therefore the main gearshaft ought to be perfectly in line with the clutchshaft. It is, however, recommended that a simple universal coupling, preferably of the spring-steel-ring or Schneider type, be employed as this is very easy to disconnect without taking down either part of the unit, and also reduces the accuracy in boring necessary by a small fraction of an inch. Naturally the clutch would be enclosed completely; the lid or cover giving access to it may be either an aluminum casting or a steel pressing.

Four Speeds and Reverse Needed

Turning now to the gear-box, four speeds with a reverse should, of course, be provided. Wheels with big teeth are preferred. Considerable width of tooth is also an advantage from the point of view of silence. The spigot should run on ball bearings, but the main shaft and layshaft may be mounted on either ball or taper roller bearings. The advantage of using the latter is that it eliminates the otherwise absolutely essential thrust race on the mainshaft. Concerning the arrangement of the gears, and the striking mechanism inside the box, no departures from the normal practice are considered, but the control should undoubtedly be in the center of the chassis, the gate thus coming immediately on top of the gear-box. Probably the best arrangement for the gear-shifting lever is to mount it on a ball which is automatically dirt-proof and self-lubricated. There are, however, disadvantages in not having a visible gate, but there is a design entirely adaptable for such a layout as the one under consideration.

It is not proposed to discuss axle arrangements at the present time, but it is believed that the best arrangement, considering the advantages and disadvantages of all systems, is to have a single universal joint behind the gear-box, contained inside a large ball, the latter forming the end of a substantial tube containing the propeller-shaft. This tube acts as the driving member, as a radius- and as a torque-rod. The arrangement can perhaps be improved by the addition of side rods, but they are in themselves troublesome in certain respects and it is doubtful whether the sum total of gain in having them amounts to anything at all. The possibility of side-sway from lack of rigidity can be overcome by the use of wide springs with well-proportioned eyes and carefully fitted shackle bolts. One essential of the arrangement suggested is that the ball be of thoroughly adequate diameter; somewhere in the neighborhood of 5 inches is suggested as about right for a car of the size under consideration. The universal joint contained therein would preferably be of the ring type with ball bearings, or again, taper roller bearings, as these types appear to be everlasting. The torque-tube would, of course, be steel; the ball should be phosphor-bronze.

Steel Gearbox End

It now remains to consider the way in which the thrust from the ball should be applied to the car as a whole. It is suggested that the end of the gear-box be of cast steel and that the ball housing be machined in this. Near the forward end of the power unit on the sides of the crankcase would be a pair of substantial pads, placed vertically, to which a pair of drop forged arms could be attached. It would be possible to use the ordinary cast aluminum arms, but it is deemed preferable to take the drive through steel. The ends of these drop-forged arms would be turned spherical, giving balls about 2 inches in diameter, and a similar ball would be bolted firmly on the gear-box by a pair of long bolts passing right across the steel casting on either side of the large ball at the rear end. The necessary sockets would be placed on the side members of the frame for the front ends, and on a cross member for the back end. This arrangement would avoid the necessity of any dropped or bent cross members, thereby avoiding weakness and expense; would relieve the unit from all twisting stresses and provide ample area for driving. It might be an advantage to mount the socket for the ball at the rear end, itself on a swivel, so that the whole of the driving force would be applied through the two arms; this would dispense with the possibility of undue load being placed on any one ball through disalignment of the frame. Conversely, it might be preferable to take all the drive through the single suspension on the cross member at the rear and allow the front sockets a little swing. Probably convenience in manufacture and erection would be the deciding factor. One detail which has not been mentioned is that the universal joint should be allowed a little telescopic movement on splines, on either the propeller-shaft or the gear shaft. This would compensate for any inaccuracies in erection and also make it possible to withdraw the whole transmission by removing the back half of the cast steel sphere-casing. It might be pointed out that this latter provides a unit which can be fitted in the frame very easily, and which is entirely independent of any necessity for lining up to the rear axle. The system described is likewise a complete unit and the only great accuracy required in the spring mounting on the frame is to see that the two axles are parallel.

Steering-Gear on Crankcase

The steering-gear would be bolted to the crankcase on the left-hand side of the engine, as left-hand drive is undeniably the only possibility for American usage. This would leave the right-hand side of the engine very clear for obtaining access to the motor starter and the oil tank, if the Wolseley arrangement were adopted. It is suggested that if a cross-shaft is used the magneto should be so placed that its contact portion is accessible from the left-hand side. It is an advantage to have such parts as carbureter, magneto and lubrication details so placed that they can be all inspected at the same time with the minimum amount of moving about.

Engine control should consist of hand-throttle and spark lever on the steering-wheel, and also a well-balanced foot-throttle, so operating that the hand-lever controls the cut-off. The throttle-pedal should be situated immediately behind the base of the steering-column and between the brake- and clutch-pedals. An arrangement of steering-gear which allows for a slight adjustment for rake is also recommended, not to enable different angles to be obtained for different styles of body-work, but to allow the driver a little latitude as to the closeness of the wheel. This is a point which has been neglected very much indeed, but there is no doubt that a large man is far better suited by a wheel rather higher up and rather further forward than a small man. All that is needed is an arc of travel giving about 3 inches of movement measured at the top end of the column.

Electric Type of Starter

For the motor-starter it will be possible to fit an electric dynamotor either at the forward end of the crankcase on the right-hand side to mesh with the flywheel, or—and this would probably be much neater—on the right-hand side below the valve level and at the back end, taking the normal drive in the most convenient way, preferably by chain from the camshaft and using a small sliding gear or a little epicyclic train to provide a gear-down for starting. Yet another place where the dynamo can be fitted is on the side of the clutch-case, the outside of the clutch being toothed.

The carbureter is outside the scope of the present discussion. Just as with inlet-pipe arrangements, the best carbureter for any engine is usually found by a process of trial and error.

The only other detail of which no particular mention has been made is the water pump, the only requisite for which is that it should be sufficiently powerful to cope with any climatic conditions likely to be encountered. It should be of a centrifugal pattern which allows fairly free syphonic circulation, if the drive fails; it should have an easily adjustable gland, and a weak coupling between it and its driving-shaft, which will fracture readily should an attempt be made to start the engine with the pump frozen.

Force Fuel Feed

The method of fuel feeding probably most satisfactory is to force fuel by air pressure from a large tank through a small tank on the dashboard to the carbureter. This small tank will trap sufficient fluid to enable a start to be obtained and to give a few minutes' running without the necessity of pumping up the pressure-system by hand. To supply the pressure there should be a plunger air-pump, the clearances being calculated so that it is never possible to deliver air at more than about five or six pounds per square inch. This pump might be driven direct from the camshaft or incorporated with one of the oil pumps. I can quite understand that in America there is a liability for pressure joints to work loose, but even if a gravity dash-tank were used, I would prefer to maintain the feed by pressure, and in such case the pipes would be so short that I think vibration troubles need not be feared. One cannot obtain efficiency with a long inlet-pipe and it is impossible to avoid the use of a long inlet-pipe with a gravity-feed because the tank cannot be mounted at a sufficient altitude, even on the dash, if it to hold enough gasoline for 200 miles. It would, however, be possible to devise a dashboard tank with two compartments and to use the pressure merely to lift fuel from the bottom compartment to the upper one.

Band Brake Useless

The contracting-band type of brake ought not to be considered. It has only one advantage, which is that it is easy to make very cheaply. A band-brake is never powerful, never quick in action, never easy to adjust, invariably gives rise to rattle (as it contains of necessity a large number of joints which get lubricated principally with mud) and moreover is extremely unsightly. Granting that extremely good working surfaces for brakes are steel and woven material such as has been recommended for the clutch, the best arrangement from all points of view seems to consist of wide cast steel drums, ribbed for cooling, fitted to each rear wheel, and two sets of shoes side by side each faced with lining material, one pair operated by the hand-lever and the other pair by the right-hand pedal. Such brakes can be enclosed completely so as to be protected from dirt.

The best operating system is to run the two pull-rods slightly above the torque tube, actuating the expanding cams of the outer pair of brakes by means of shafts, taking one bearing in the brake bracket at each end and the other bearing in the differential case;

the other pair of brakes being controlled from tubes rotating on the outside of the said shafts. These are best situated above the axle and are neater and less troublesome to erect than cross-shafts on the frame itself. The ends of the operating arms would, of course, be connected by an ordinary compensating link. For adjustment and setting, hand-tensioning wing-nuts would be applied to the pull-rods and there should be some arrangement whereby the operating arms can be set relatively to the spreading cams, so that as wear takes place the levers can still be kept in a normally vertical position. It would be easily possible to arrange for the lubrication of the bearings of the brake-operating shafts at the inner ends, from the inside of the differential box. The bearings at the outer ends can be supplied with grease from the same cup that feeds the bearing between the spring table and the axle sleeve. Thus the whole of the connections should be lubricated by means of a single pair of greasers on the axle.

Steering-Gear and Control Parts

There is no doubt that ultimately all front axles will be designed with the steering swivel-pin inside the hub and in the plane of the wheel, because this arrangement removes all possibility of shock in the steering-wheel, gives absolute security on the roughest roads and enhances the durability of the steering-gear enormously. The only disadvantage is the necessarily large bulb which has been considered rather ugly. If such a matter is deemed important, care should be taken that ample ball thrust-bearings are provided in the swivel-pins and in the steering-gear itself. There is only one pattern of ball-joint for steering connections which is absolutely secure and this should, of course, be ample. For the control through the steering-column the simplest possible arrangement should be employed, as a great many controls which are used at the present time contain a very large number of totally unnecessary moving parts.

Balso Co. Considers Motor Condition in Specifying Lubricant

TOLEDO, O., June 22—The Balso Oil Co. of this city has taken up the lubricating problem in a new manner. In selling oil to the car owner the motor is divided into five zones of wear. The first zone is when the motor is new and the fifth is when it is worn out in the moving parts and just about ready for the scrap pile. Between these two extremes are the other three zones. The owner of the car first determines in what zone his motor lies and then proceeds to answer the questions on the chart shown in Fig. 1. This is mailed to the Balso Oil company's office and from it the particular needs of that owner are determined.

It is the aim of this system to meet the need of each individual motor. Only three factors in lubrication are noted, first the rapidity or tension of flow, second ease or rapidity of burning, third rapidity in scavenging or consuming the carbon.

The first is theoretically shown by the viscosity according to the Tagliabue viscometer at 70 degrees Fahrenheit and is practically shown by the ability of the oil to retain its correct flow past the rings of the piston at working temperatures. The flow of the oil is theoretically regulated in the laboratory as follows:

First Zone, perfect fit	230 Vis.
Second Zone, clearance 1/1000 of an inch.....	430 Vis.
Third Zone, clearance 2/1000 of an inch.....	630 Vis.
Fourth Zone, clearance 3/1000 of an inch.....	830 Vis.
Fifth Zone, clearance 4/1000 of an inch.....	1030 Vis.

or 200 points in viscosity per 1/1000 inch looseness or wear.

Second.—The rapidity of burning. This must be shown by the fire test, starting in the First Zone at 440 degrees Fahrenheit, advancing slowly in steps of 8 degrees in each consecutive zone, giving a 464 fire test in the Fifth Zone, which is very low, and in direct opposition to the theory of many engineers of the old school.

Balanced oil standing in the Fifth Zone in some instances has 100 degrees less fire test than many other automobile oils of equal viscosity.

Third.—Rapidity of scavenging or rapid decarbonization is shown by the tenacity of the carbon deposits, and their tendency to cleave from the metal and also by the rapidity with which it becomes incandescent from the heat of explosion.

In experimenting on the question of carbonization, the Balso company finds that too much attention has been paid to carbon content which ranges from 1 per cent. down to hundredths of 1 per cent. in distillates. This they claim to be a negligible quantity to a motor using a normal quantity of oil. When it was finally found that often excessive carbonization which was attributed to poor oil, really came from the carbon clinging to the metal, instead of being ejected, it became apparent that the quality of oil was important.

Carbon deposits show a wide range of consistency. Those from a high gravity high fire test oil being hard in consistency and difficult of expulsion, while those of the extreme low gravity and low fire test oil are more easily handled, having a cleaving action.

By experiment with different base oils the Balso company states it was found that the blends produce different consistencies. By working along these lines the company claims a balanced oil. The Balso company considers that the fight between the paraffin and the asphalt bases is interminable, the arguments on both sides being inexhaustible.

To bring out the points of its arguments the Balso company has issued a booklet entitled Bunco in which thirty-two pages are devoted to exploding various oil theories held by manufacturers, salesmen and owners. This book is designed to explain the value of the "zone system" of lubrication.

BALSO'S BALANCE SHEET

THE TEST CHART

For the Balanced Lubrication of all Internal Combustion Motors, with SPECIAL reference to Automobiles.

In which stage of WEAR do you consider your motor to be NOW? ....

Have you had the moving parts of the motor refitted or cleaned? ....

What was the opinion of the party who did the work? ....

What was your opinion? ....

Have you ever run your motor for any length of time when it was RED HOT? ....

If so, after that did you notice an increase in OIL TROUBLES? ....

How often do you wash out the Crank Case, putting in new OIL? ....

What did you do with the OLD OIL? ....

What Oil do you use mostly? Name..........Color: Lemon.... Amber.... Red....

What Oiling system have you? ....

Direct SPLASH from Crank Case? ....

Combination Direct with sight dash feed? ....

If any other kind describe..........

Are the Carbon deposits in the firing Chamber thin?.....Hard?.... Glassy?.... Thick?.... Soft?.... Dull?....

Are the Spark Plugs placed over the intake valve or side vestibule? ....

Are Spark Plugs over the piston entering the main firing chamber? ....

Is there any difference in the compression when the Motor is hot or cold? ....

Note here any SPECIAL trouble you have; for example: If one piston passes more oil than the others.....

Wants to Be an Engineer

EDITOR THE AUTOMOBILE:—1—I have just graduated from high school and wish to become an automobile engineer. Will you kindly advise me as to which of the following two courses would best equip me for the above vocation: The first course is a 3-year B. S. course at Columbia University, plus a 3-year M. E. course at the same place. The second is a 4-year M. E. ccurse at Polytechnic Institute of Brooklyn, plus 2 years of post-graduate work in electrical engineering at the same institution.

2—Will you also give me any particulars that you are able to, as to salary, position, etc.?

Brooklyn, N. Y. J. MOZER.

—1—The selection of the proper school is a serious problem and doubly difficult for one just out of high school. We do not feel that it is our place to advise you as to whether you should go to Columbia or the Polytechnic Institute. This is something you should decide for yourself, and only after due consideration. You should obtain a syllabus of the courses offered by each school, and study both carefully. Compare the two. Find out how many hours each devotes to drafting and machine design, how many to mathematics and electricity and so on. Then go to these two schools, and become acquainted with some of the men in charge; tell them that you do not know which school to choose and get their arguments as to why their school is best. You will find the professors glad to advise you.

Examine the laboratory equipment, and find out how many of the professors of each school are holding important positions, and what their standing is.

Finally, weigh all the facts you have in hand carefully, and decide which school will teach you the most about the subjects you desire to have knowledge on, considering the number of hours devoted to these subjects, the personnel of the teaching staff and the excellence of the laboratory equipment.

2—As in everything else, the position that you will obtain after graduation and the success you will make in your line depends largely on yourself; on how much you learn in college and what ability you display to apply this knowledge.

It is impossible to give very exact information as to the salaries that are paid by the automobile factories, because the wages for a given position depend largely on the prosperity, size and generosity of the individual concerns. To give you a rough idea you will get from $12 to $20 per week at the start. In years you may work up to be chief engineer at from $5,000 to $15,000 a year, or more; chief draftsman at about $2,000; purchasing agent at about the same amount. A consulting engineer may make $10,000, or more a year. Five thousand dollars is a good salary for an experimental engineer.

A New Explanation for Overheating

Editor THE AUTOMOBILE:—I notice in your issue of Sept. 3 a letter from J. W. L. of Ogden, Utah, in which he states it is impossible to keep his motor from overheating, also that he is using "as lean a mixture as possible." In your reply you say a rich mixture will overheat a motor. Now I trust you will pardon me for contradicting you, but I feel compelled to say that this is not the case. A rich mixture will not overheat a motor, or at least any excess of heat developed would be so slight as to be negligible. On the other hand, one of the surest ways to overheat a motor is to use a lean mixture, and inasmuch as J. W. L. is using his as lean as possible it is no wonder that his motor heats.

I realize that a number of motor drivers do not agree with me on this point, but as a matter of fact it is not a question of personal opinion, but of fact. Even though I have always been entirely sure of my ground I have at various times made tests which have determined this beyond a possibility of a doubt. Moreover, if one will consider the matter for a moment, he will realize that the lean mixture must of necessity be the greater heat producer.

A lean mixture is a slow burning mixture while a rich mixture is not. This is clearly indicated by the fact that the former will fire back into the carbureter, while a rich mixture never does. A rich mixture fires with reasonable promptness or misses altogether, while a lean mixture never misses, but burns slowly, and the leaner it becomes the more slowly it burns. It is this slow burning, this constant flame in the combustion chamber, that overheats the motor. As a parallel I will cite the ordinary household gas stove, in which, as everybody knows, an intense heat is created by adding a considerable quantity of air.

Of course, the really correct way to determine this, as any other question, is by actual test, so I respectfully suggest that J. W. L. enrich his mixture considerably and abide by the results.

Detroit, Mich. F. R. PENDLETON.

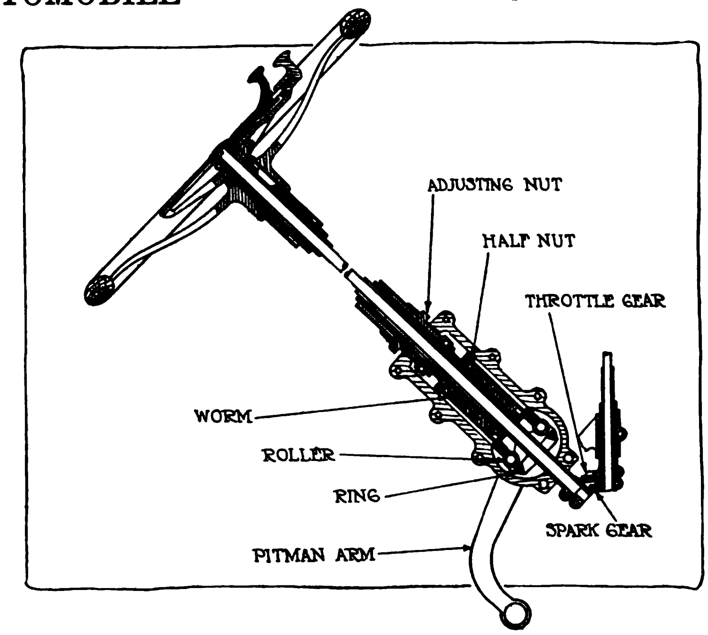

Fig. 1—Buick model 24 steering gear showing construction and adjustment

How to Adjust Steering Gear

Editor THE AUTOMOBILE:—1—Kindly give me through your Rostrum, a sketch of a Buick 24, 1913 steering gear, and its adjustment?

2—How does this steering gear operate?

3—Give me a sketch of how the holes are bored, how many and what size, around pistons to eliminate oil in the head.

Webb City, Mo. FRANK B. PATRUM.

—1—There is just one adjustment on this steering gear which is shown in Fig. 1. This is the nut which screws into the housing around the jacket. Tightening this nut acts on the ball thrust bearing and takes up all the back lash in the hand wheel. It should always be kept so tight that the wheel can only move an inch or so before affecting the road wheels.

Unless you are certain that the play is here, it is better to first lift the front wheels from the floor, so that the wheels are free to turn. Whether the wear is here, or in the tie rod or drag link, can then be easily determined. The latter is provided with adjustable ball joints so that any play can be easily removed.

2—The steering gear is the part of the car that operates on the front axle to turn the road wheels in response to the movements of the hand wheel. Buick automobiles are equipped with an irreversible steering gear of the worm and nut type.

The steering gear consists essentially of the steering tube, to the upper end of which is attached the hand wheel, while the worm is keyed to the lower end. The worm meshes with two half-nuts in the housing, one of which has a right hand thread and the other a left hand thread. The ends of the half-nuts bear against two rollers attached to a yoke on a short shaft which projects out beyond the frame, and to the other end of this shaft is attached the pitman arm, which is connected to the third arm of the front axle by the drag link. The operation is as follows:

Turning the hand wheel also turns the tube and worm in the same direction, and as the worm turns one half-nut rises while the other descends. This pushes one roller down and allows the other to rise, thus turning the shaft and imparting the desired motion to the pitman arm, and so on to the road wheels.

The steering gear is said to be irreversible because, while the motion of the hand wheel is readily transmitted to the road wheels, the jarring of the road wheels over rough and uneven surfaces does not affect the hand wheel.

The worm, yoke, rollers and half-nuts are all enclosed in an oil tight housing which is bolted to the left side of the frame, and a ball thrust bearing in the upper end of the housing takes the thrust of the worm. The housing is kept constantly packed with grease and a pipe plug is provided on top for its renewal. A grease cup on the outer end of the shaft helps to lubricate the long bearing on the left side.

3—We would not advise you to drill the pistons. Set the rings so that the openings in them are about 120 degrees apart and you should have no more trouble unless, by some accident, the motor is defective. It seems most probable that the spaces in the ends of the rings are in line, thus offering an unbroken passage for the oil.

Gasoline Consumption High

Editor THE AUTOMOBILE:—I drive a 1913 Ford touring car which runs with usual power speed and smoothness but I am getting only about 12 miles per gallon of gasoline while I have previously made from 20 to 23 miles per gallon under the same conditions. The magneto tests good. Can you tell me the cause of this?

Sheffield, Vermont. CLINTON E. JONES.

—Anything that will use up power, or reduce the efficiency of your car, might cause this increase in fuel consumption. But before looking for the trouble, make sure that you are getting full measure when you buy your gasoline, and also that your speedometer is correct. The latter can be tested by running the car over a course of known distance and comparing the reading of the speedometer with the distance covered.

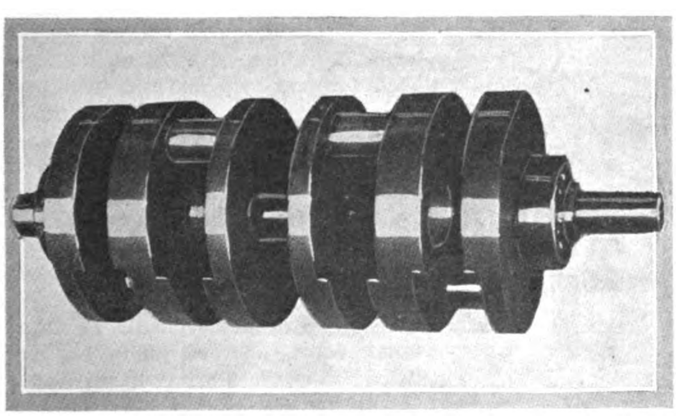

Fig. 2—Maxwell racing crankshaft. The disks connecting the crank pins supply the flywheel effect

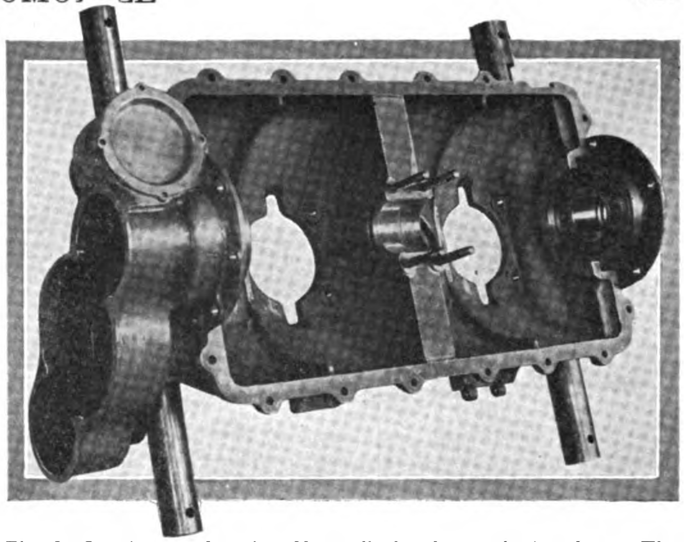

Fig. 3—Crankcase of racing Maxwell showing main bearings. The end ones are ball and the center plain

You may be driving with too rich a mixture. Cut down on the amount of gasoline fed to the carbureter and see if the consumption is not lessened, but without a decrease, and possibly an increase, in power. Make certain that there are no leaks in the fuel system. Just to be on the safe side it would be well to turn the gasoline off whenever the car is not in use, because there may be a small leakage, somewhere, that amounts up in time but is hardly noticeable.

Drive with the spark advanced as far as possible without the motor knocking. See that the spark plugs are in good condition and that the gaps are the correct size.

Next, examine the motor. The compression should be good, and if it is not the valves may need grinding or possibly the rings, pistons or cylinders may be worn.

It is possible that the high speed clutch is slipping, and by driving the car at a medium speed along the level, and then suddenly accelerating, whether this is so, can easily be determined. If the clutch is holding, the car will accelerate as rapidly as the motor.

Push the car over a level garage floor by hand and note whether it requires very much effort. It may be that the brakes are dragging or that there is excessive friction in some other part.

To Go from Reading to Butler, Pa.

Editor THE AUTOMOBILE:—Will you please let me know the best automobile route from Reading to Butler, Pa. I do not care to touch Pittsburgh if another route is just as good.

Kutztown, Pa. Q. D. HERMAN.

—If you follow good roads you will be obliged to go through Pittsburgh. Your route will lie through Harrisburg, Chambersburg, Redford, Greensburg, Pittsburgh, to Butler.

Maxwell Racing Crankshaft

Editor THE AUTOMOBILE:—Please show in a diagram how the Peugeot and Delage and Maxwells arrange their ball bearing crankshafts in their racing cars.

St. Louis, Mo. F. SMITH.

Fig. 2 shows the Maxwell crankshaft. Illustrations of the Delage or Peugeot crankshafts are not obtainable. Ball bearings are used only at the ends of the Maxwell motor, the center bearing being plain. The mounting of the bearings is clearly shown in Fig. 3.

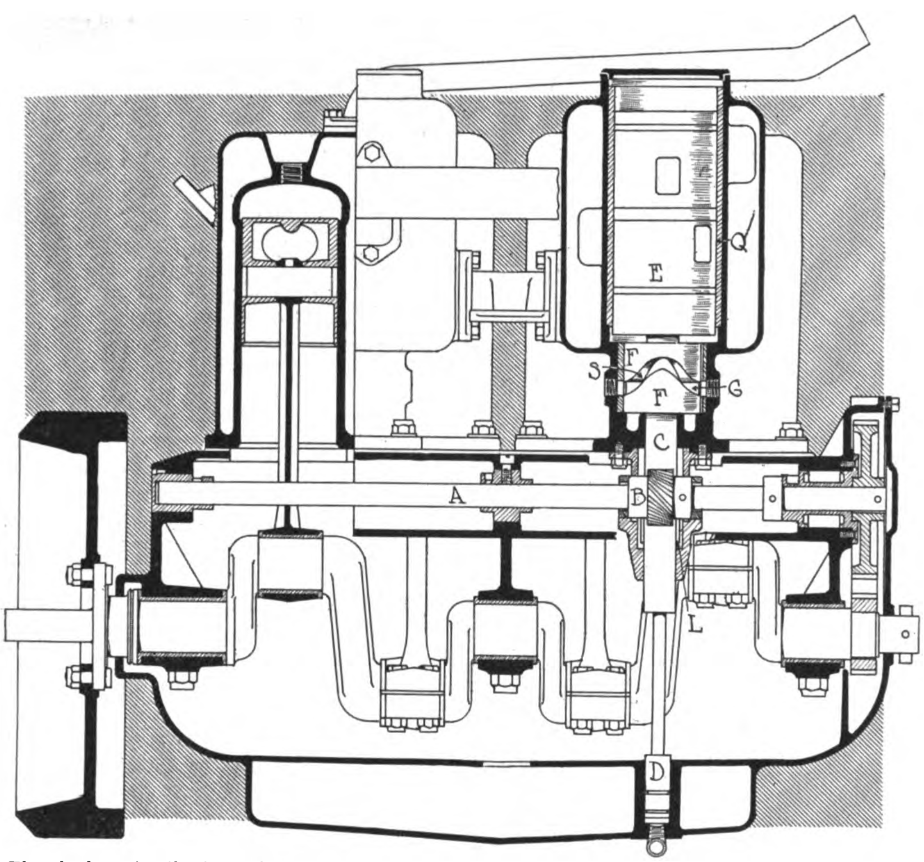

Fig. 1—Longitudinal section through valve action and cylinders of Doherty piston valve engine

Doherty Engine Uses Piston Valve Action

Follows Standard Construction

AN engine actuated by a rotating-reciprocating valve has been invented by H. B. Doherty of Wilkesbarre, Pa. The engine is really a modification of the piston valve design, in which a cored cylindrical valve performs the functions of inlet and exhaust for two cylinders adjacent to one another. That is, for a four-cylinder engine two piston valves are employed.

Spiral Gear Drive

Other than the valve and ports the engine is of standard construction. The valve, however, is different from any of the previous piston designs which have recently been brought out. A plan view of the layout is given in Fig. 3, showing the positions of the cylinders and valves. The valve is slightly larger in diameter than the bore of the cylinder and in position the two cylinders and the one valve resemble a three-leafed clover.

The ports through the cylindrical valve are so arranged that as it reciprocates the needs of one cylinder are first taken care of and then those of the adjacent cylinder. The first cylinder is controlled by the rotating part of the valve motion and the second cylinder by a reciprocating motion that is furnished by a cam.

The manner in which this valve is driven is as follows:

A horizontal shaft extending the length of the crankcase and corresponding in its action and drive to the cam-

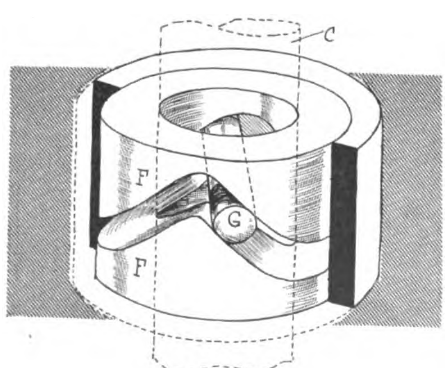

Fig. 2 — Drive of rotating-reciprocating valve

shaft of the ordinary poppet motor is fitted with two spiral gears to take care of the drive of the valves. The horizontal shaft A, Fig. 1, is driven by spur gears off the crankshaft and by means of the spiral gear B rotates the vertical reciprocating shaft C. The shaft C carries the valve with it in a rather unusual manner. The vertical shaft C is provided with a feather L on each side of the shaft, permitting the gear which meshes with the spiral gear B to slide vertically upward and downward on the reciprocating shaft. At the top end of the shaft is the valve E which is fastened to the shaft.

One-Inch Travel

The reciprocating action of the sleeve is accomplished by the drive from the spiral gear which rotates it and permits of the action of the cam slot S on the pin G. The action of this cam is to give the sleeve a reciprocating motion of 1 inch, besides its rotary action.

In manufacture the accuracy of the port sizes is insured by the use of a liner Q which is inserted within the valve cylinder. In the liner there are four ports, one for the intake and exhaust of each of the two cylinders. The liner is fitted between the outside casting which holds the valve and the piston valve itself. Four junk rings make the joint tight between the piston valve and the liner.

Oil Pump Lubrication

Every time the valve is revolved once by the spiral gears it moves up and down twice on the cam. The valve ports are so spaced that one set is 1 inch below the other set, the difference in height being due to the reciprocating motion which is provided to furnish a sealing space between the openings for each cylinder. As the inlet valve for the first cylinder is opened by the registering of the ports, this cylinder draws in its charge and the valve continues until it has closed this intake by rotating a distance equal to the width of the port. It is then lifted by means of the cam and the next port in turn comes into position in front of the next cylinder. Thus the valve operates on two levels, finishing its work on the lower level for one cylinder and then being lifted 1 inch to perform its functions on the next cylinder.

The oil pump for lubricating the sleeve has been provided for in a very ingenious manner. The vertical reciprocating rod has been extended downward and at its lower extremity the plunger pump D has been fitted. On the bottom of the vertical rod for the other valve, another pump has been fitted for use in storing up pressure in the air tank.

In the manufacture of an engine of this design the construction is practically the same as in the ordinary poppet engine with the exception that the core work in the cylinders and valve is different from any other design. An idea of this is given in the accompanying illustration which shows a section through the piston and also through the cylinders and valve chamber. The inlet manifold is formed directly by cored passages in the cylinder casting manifold bolts directly to the outside of the casting, and runs vertically instead of horizontally.

Drilled Oil Passages

The motor is oiled by a force-feed system through leads which are carried from the plunger pump previously described. The cylinders are lubricated by the oil thrown off the crankshaft bearings. Oil passages are drilled diagonally through the crank sheets in connection with the force speed system. The area of inlet and exhaust is shown in the accompanying diagram and a chart of mean gas speeds through the inlet valve. The valve runs at one-quarter crankshaft speed. The inlet opens 10 degrees past upper center and closes 40 degrees past lower center, giving an opening of 210 degrees. The exhaust opens at 50 degrees before lower center and closes 10 degrees before upper center, giving an opening of 220 degrees.

The area of the ports and the mechanism for driving the valve with its combination rotating and reciprocating motion, are so designed that the curve of gas speeds through the inlet valve for increases in revolutions per minute, is a straight line. This curve is shown at the bottom of this page and it will be noted that at normal speeds of say 1,800 revolutions per minute, the mean gas speeds through the inlet valve will be about 20,000 feet per minute. This layout of valve ports with its straight passages and wide opening, should permit of exceptionally high speeds.

As will be noted from the horizontal section, the layout of cylinders and valve permits of ample water jacket space. Each passage through the valve serves as the inlet and exhaust for one cylinder and this is another factor in the cooling arrangement because the exhaust gases heat the passage as they pass out and the inlet gases in turn absorb this heat cooling the passage and at the same time becoming preheated.

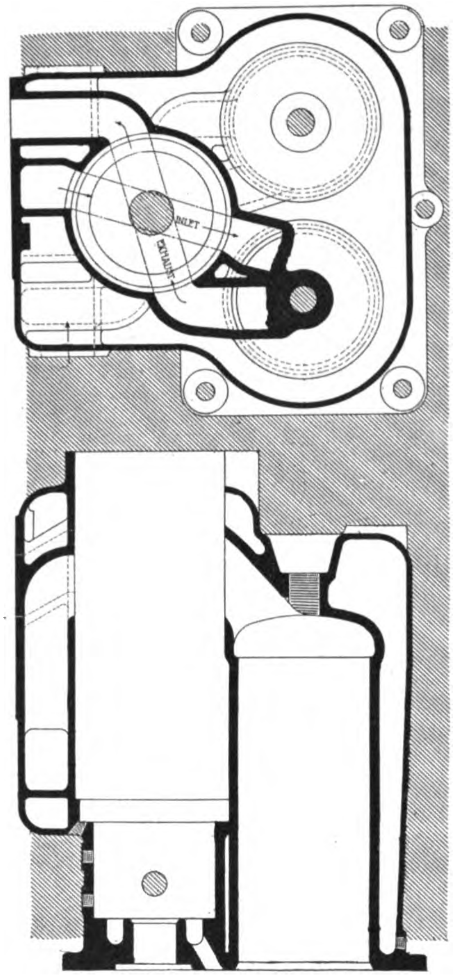

Fig. 3—Vertical and horizontal section through valve and ports

No Leakage

The method in which the ports register with the opening in the valve is shown in Fig. 3. Leakage is prevented by the valve being provided with packing rings and also by vertical packing. The action of the cam in bringing the valve to registry with the different ports is clearly shown in Fig. 2. By elevating one port above the other, a very compact arrangement is secured without materially increasing the height of the engine.

Multiple Disk Clutches

These clutches are, as a rule, delightful, but, like most parts of a car, they need occasional attention. With regard to the type running in oil, it will usually be found difficult when starting from cold in the morning to engage a gear unless the clutch is held out an abnormally long time. A quick way is to press out the clutch and at the same time race the engine once or twice quickly. This will generally throw off the congealed oil and permit the clutch shaft to stop. On my car I have the pattern which runs dry with no lubricant, with steel and bronze alternate plates. Occasionally the plates refuse to separate, and the clutch will not stop spinning when the pedal is pressed out. The remedy is to prop the clutch out of action, squirt paraffin between the plates, run the engine to throw off surplus paraffin (with clutch still disengaged), then wash out with gasoline, paraffin having a tendency to rust steel. As soon as the clutch becomes "dirty," it will refuse to stop, hence the noise when engaging the gears.—*T. Haley in The Autocar.*

WHEN a car has been in service for some time it generally develops annoying little squeaks here and there about the springs and body. The owner or driver will find it well worth while to get rid of these, as the labor involved is slight and a quiet, smooth-running car is always desirable. Squeaks can generally be remedied by tightening the car parts affected or by the application of a little adhesive tape.

New Books for the Engineer

Several New Works on Tools and Shop Practice — Metal Statistics for 1914 Published

MACHINE Shop Tools and Shop Practice is an excellent book for those interested in this work. There is also a book on tool making and one on American lathe practice, both published by the Norman W. Henley Company, the former being by Joseph V. Woodworth and the latter by Oscar E. Perrigo. Local Ordinances Relating to Speed and Traffic Regulations is a book written by Mitchell May, secretary of the state of New York.

MACHINE SHOP TOOLS AND SHOP PRACTICE. By William H. Van Dervoort, M.E. The Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 552 pages; 673 engravings, $3.

This book, which is the sixth edition, is the outgrowth of a series of articles prepared by the author for the students in machine shop practice at the University of Illinois. An effort has been made to treat the subject in a clear and comprehensive manner, carefully avoiding all unnecessary matter and presenting to the apprentice and mechanic many points pertaining to the tools with which they come in daily contact, and about which they are often unable to obtain all the information necessary, in order that they may use these tools correctly and efficiently.

In treating on the various classes of small and machine tools, the author has endeavored to bring out much pertaining to the advantageous use of these tools.

The importance to the machinist having at least a limited amount of information on the subjects of Fastenings, Gearing, and Belting and Transmission Machinery has prompted the addition of chapters upon these subjects.

METAL STATISTICS FOR 1914. Seventh Annual Edition, issued by The American Metal Market and Daily Iron and Steel Report, the American Metal Market Co., New York City. 280 pages with advertisements; cloth.

Small enough to be conveniently carried around in the pocket this little book is designed for buyers, sellers, plant managers and engineers as a guide in purchasing both ferrous and non-ferrous metals.

The monthly production in tons and the average monthly price of the various classes of metals are given in tabular form. The statistics include figures on iron and steel, pig iron, finished products, scrap, copper, tin, lead, spelter, aluminum, antimony, silver, and miscellaneous.

AMERICAN TOOL MAKING AND INTERCHANGEABLE MANUFACTURING. By Joseph V. Woodworth. The Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 531 pages, 600 illustrations, $4.

A "shoppy" book, containing no theorizing, no problematical or experimental devices, there are no badly proportioned and impossible diagrams, no catalogue cuts, but a valuable collection of drawings and descriptions of devices. In its 500 odd pages, the one subject only, Tool Making, and whatever relates thereto, is dealt with. It is a complete practical treatise on the art of American tool making and system of interchangeable manufacturing as carried on today in the United States. In it are described and illustrated all of the different types and classes of small tools, fixtures, devices and special appliances which are in general use in all machine manufacturing and metal working establishments where economy, capacity and interchangeability in the production of machined metal parts are imperative. The science of jig making is exhaustively discussed, and particular attention is paid to drill jigs, boring, profiling and milling fixtures and other devices in which the parts to be machined are located and fastened within the contrivances. All of the tools, fixtures and devices illustrated and described have been or are used for the actual production of work, such as parts of drill presses, lathes, patented machinery, typewriters, electrical apparatus, mechanical appliances, brass goods, composition parts, mould products, sheet metal articles, drop forgings, jewelry, watches, medals, coins, and so forth.

The treatment of each tool described and illustrated is such as to enable any practical man to design, construct and use special tools, dies and fixtures for the rapid and accurate production of metal parts, interchangeably.

FACTORY LIGHTING. By Clarence E. Clewell, Sheffield Scientific School, Yale University. McGraw-Hill Book Co., 239 West 39th street, New York City. Cloth, 160 pages, $2.

Beginning with a discussion of the requirements of satisfactory lighting, illumination design is considered with special reference to efficiency. Lighting installation work is taken up, the Underwriter's rules stated and methods of wiring described. There is a chapter on maintenance and the keeping of records in connection with this work. Then lighting under various conditions from all angles is considered. These conditions include office drafting, factory, power house, iron and steel mill, and machine tool lighting.

MODERN AMERICAN LATHE PRACTICE. By Oscar E. Perrigo, M. E., the Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 424 pages, 314 detailed engravings, $2.50.

This is a new book from cover to cover. Written by a man who knows not only how work ought to be done but who also knows how to do it, and how to convey this knowledge to others. It is strictly up-to-date in its descriptions and illustrations, which represent the very latest practice in lathe and boring mill operations as well as the construction of and latest developments in the manufacture of these important classes of machine tools.

Lathe history and the relations of the lathe to manufacturing are given; also a description of the various devices for feeds and thread cutting mechanisms from early efforts in this direction to the present time. Lathe design is thoroughly discussed, including back gearing, driving cones, thread cutting gears, and all the essential elements of the modern lathe.

The classification of lathes is taken up, giving the essential differences of the several types of lathes, including, as is usually understood, engine, bench, speed, forge, gap, pulley, forming, multiple spindle, rapid reduction, precision, turret, special, electrically-driven lathes, etc.

LOCAL ORDINANCES RELATING TO SPEED AND TRAFFIC REGULATIONS. By Mitchell May, Secretary of the State of New York. J. B. Lyon Co., Albany, N. Y.; 110 pages; paper.

This is a convenient vest pocket pamphlet for the motorist that desires to keep informed on the different traffic regulations. The book is very complete, over 200 cities, towns and villages in New York State being included.

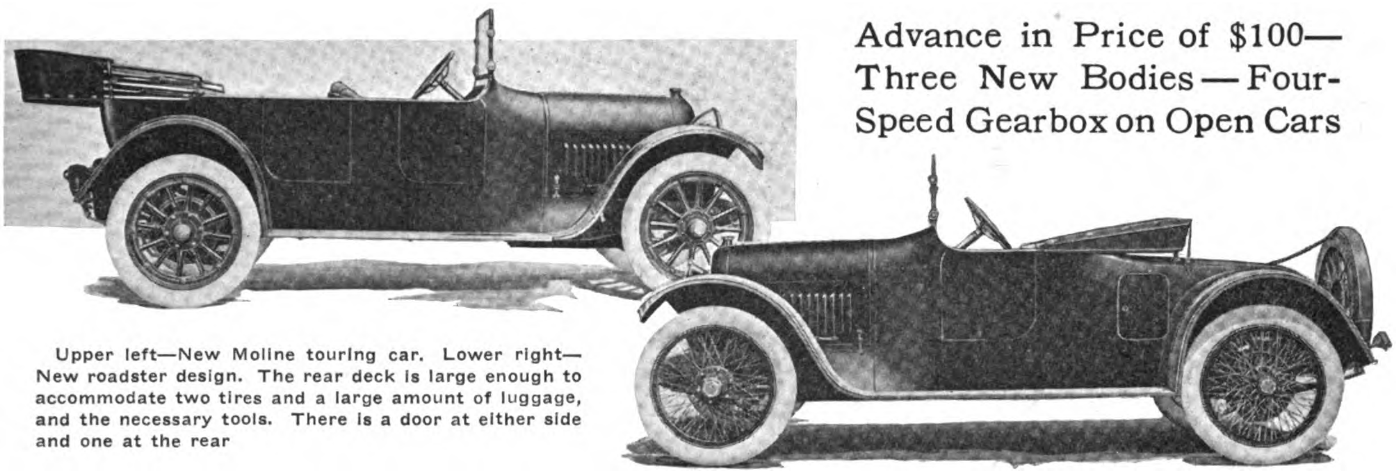
THE YOUNG MAN AND THE ELECTRICAL INDUSTRY is the title of a story, written by James H. Collins, the well-known magazine writer, which has just been issued by the Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.

The little book deals with the opportunities afforded a young man in this industry and the different lines in which he may direct his activities as exemplified by the works of the Westinghouse Electric Company.

The company announces that it will supply a copy to anyone interested in it.

New Moline Sells for $2,500

Advance in Price of $100—Three New Bodies—Four-Speed Gearbox on Open Cars



Upper left—New Moline touring car. Lower right—New roadster design. The rear deck is large enough to accommodate two tires and a large amount of luggage, and the necessary tools. There is a door at either side and one at the rear

THREE important chassis changes, a rise in price from $2,400 to $2,500 and three additional body styles, a limousine, berline and roadster, briefly summarizes the difference between the new series Moline-Knight and that marketed heretofore by the Moline Automobile Co., Moline, Ill.

Of the three major chassis changes, one is in the motor, another in the gearset and the third in the rear axle.

The exhaust manifold no longer is an integral part of the cylinder casting and now is not water jacketed, this change having been made to obtain more efficient cooling of the cylinders and still leaving the trim appearance of the engine unaltered. The new manifold is held to the casting by ten bolts. To retain the symmetrical semblance an aluminum cover is placed over the manifold, this cover having the same contour as the intake manifold, hence the apparent likeness to the older motor.

Uses Four-Speed Gearset

Unit power plant construction has been abandoned in the touring and roadster models. The new series has separate units and instead of employing a three-speed gearset, a four-speed type with direct on third is used. The four-speed unit called for the separation of motor and gearbox and four-point motor suspension instead of three. The two points at the rear are rather close together and allow of proper movement through frame distortion. The adoption of the four-speed set brought with it the desired result of eliminating entirely the magnified gear noises, due to the sounding board effect of the rather large aluminum housing. This formerly inclosed both clutch and gearbox, and was an integral part of the motor crankcase.

Gearset on Sub-Frame

The new gearset is larger than the three-speed of the past series and its installation has necessitated the use of a sub-frame. The new position of the gearbox has resulted in the shifter lever, starting lever and emergency brake control being nearer to the front seat and as an added refinement a new type of lever mounting is employed which makes a much neater job than that used formerly. With these advantages of the new installation there is another, characteristic of four-speed sets with a geared-up fourth—the car's flexibility is increased. The car can be driven as low as 5 miles per hour on third, while the minimum on fourth is 7 miles.

The third change is one which will be appreciated by devotees of silent operating mechanism—the spiral bevel rear axle gears. This type of drive, introduced some time ago by the Packard company and which is in use by a number of makers so far, offers the advantages of both the worm and straight bevel gears and is said to be minus the disadvantages of either. Thus, in the Moline-Knight the last step has been taken toward reaching the ideal as regards a silent vehicle.

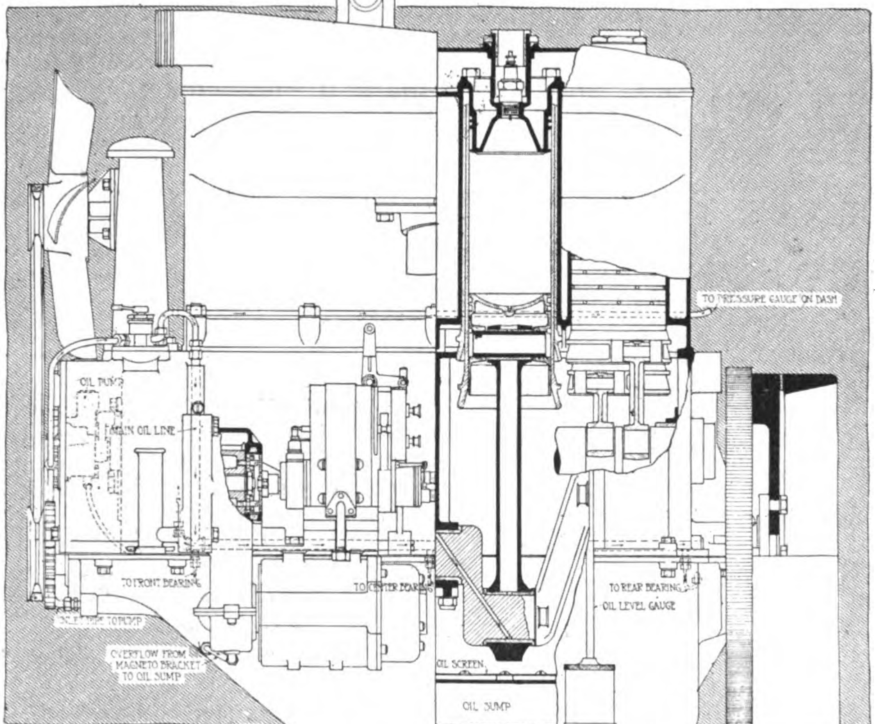
Minor Alterations Appear

Four further changes have been made aside from those just mentioned, but they are not of such importance as to call for a detailed analysis. The first of these minor alterations is the substitution of Whitney chains instead of those used in the past model, for driving the motor shafting, the second, the adoption of a screw-and-nut steering post for the worm-and-sector, the third the removal of the cranking motor switch from the motor casing and installing it as a separate unit, and the fourth change relates to the equipment and is in the form of a new single-cylinder Stewart power tire pump, instead of the two-cylinder pump of other make, used in the previous series.

The Moline-Knight line for the coming season comprises a five-passenger touring car ironed for two extra seats, its price being $2,500 with $40 additional when the two extra seats are desired, a new two-passenger roadster with a cleverly designed body at the same price, a limousine at $3,800 and a sedan at $3,250, all of these being mounted upon a single chassis with a wheelbase of 128 inches. In the case of the limousine and sedan, as mentioned previously, a three-speed gearset in unit with the engine is used.

The four-cylinder Moline-Knight motor which created a sensation in January by running for 336 consecutive hours without a stop and with throttle wide open delivering an average of 38.3 brake horsepower has 4 by 6 inch cylinders and during its official test, showed a maximum of 53.6 horsepower at 1,682 revolutions per minute. This engine in its fundamental mechanisms is similar to most motors of its type, in that it uses an inner and an outer sleeve operated from an eccentric shaft in each cylinder, but aside from this it is at variance with other Knight practice. It becomes a particularly interesting piece of engineering when it is compared outwardly with other designs.

In the first place its cylinders are cast in block, the only



Part vertical section through Moline motor showing details of construction. Note the domed pistons and tubular connecting-rods. Oil ducts are drilled in the crankshaft

Knight engine so constructed in this country. This casting is a series of smooth gracefully curved lines, in a way, blending into one another and giving a first-hand impression of simplicity and after a prolonged look conveys the thought of ultra-simplicity.

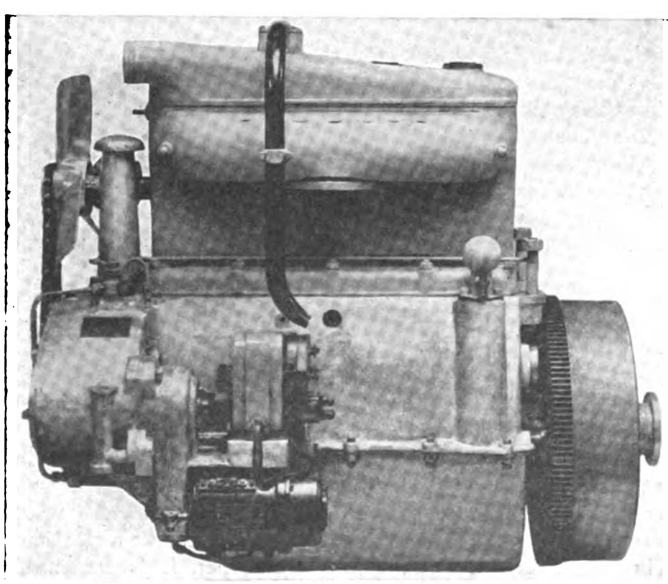
The cooling water is circulated the entire length of the cylinder barrel through the intake manifold, around the cylinder head and the reciprocating sleeves, and even around the lower portion of the spark plugs. Every part calling for cooling surface is adequately supplied, and just how this is done is well brought out in the illustration showing the end section. Note how the spark plug is inserted into a recess in the cylinder head cover and how the lower portion of the plug has water circulating around it. The tops of the sleeves also are water jacketed in the head as shown. However, a departure from last season's practice is the absence of a water jacket around the exhaust manifold.

Thermo-Syphon Cooling

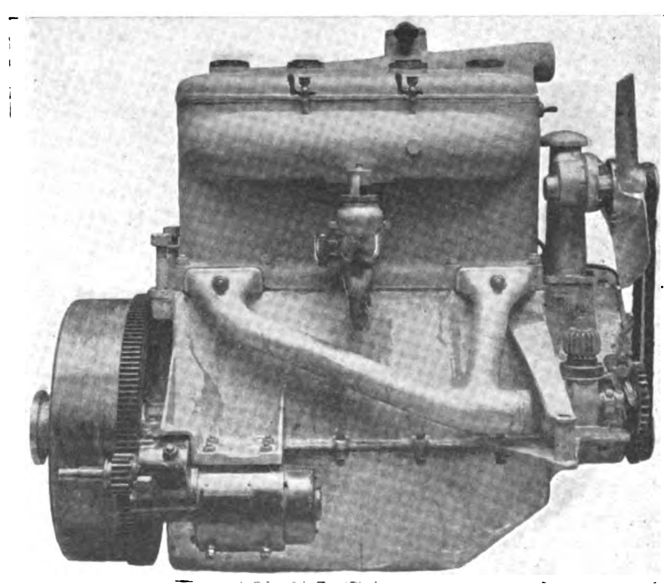
Water circulation is maintained by the thermo-syphon system, another instance of unusual construction, this being the only motor of its type which does not employ a water pump. The water in its path travels from the radiator through a two-arm manifold. These arms are attached to the lowermost portion of the cylinder block and the water passing through them is sent through the various channels mentioned previously and then returned by its natural course through the cylinder head cover which forms the return manifold. One should take particular notice of the relative size of the water pipes and the egg-shape of the motor brought about by the unusual jacketing.

Three bearings support the crankshaft, the front and center being 2 1-8 inches in diameter, and 2 1-2 inches long and the rear 4 inches long, and 2 1-8 inches diameter. These bearings have no grooves. The crankshaft drives the eccentric shaft by silent chain, this method also being used for magneto and lighting generator shaft drive. The sleeves are operated in the true Knight fashion by connecting rods fastened to the eccentric shaft which operates on bearings 1 1-8 inch in diameter and 1 1-4 inch long. These sleeves have a maximum travel of 1 1-8 inches. The intake port is 3 3-4 inches long and 1-2 inch wide and the exhaust 5-8 inch wide and of the same length as the intake. The pistons instead of being flat are concave and this with the dome-shaped cylinder head form a combustion chamber which is a big step toward the ideal chamber—the spherical. Much interest lies in the lubrication of the parts of this engine.

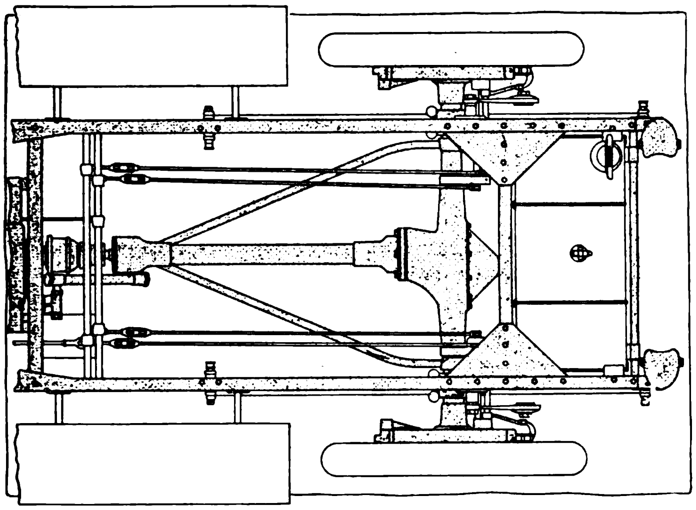
A gear pump forces oil at various pressures up to 40 pounds, dependent upon the motor speed, to every part of the engine requiring lubrication. Oil is drawn by this pump from a sump in the crankcase bottom, and forces it through a screen to a main oil duct shown in the end section of the motor. This duct, which extends along the entire length of



Left side of new Moline motor showing the mounting of the generator and magneto. The generator is under the motor arm



Right side of motor showing starter attachment, water piping, tire pump location, and three-blade fan



Rear view of chassis on new Moline showing triangular rear construction, gusseted frame and mounting of gasoline tank

the crankshaft bearing plate, is tapped at three points at each junction, a lead being sent to the main bearing opposite it. At the main bearing wrists, holes are drilled in the crankshaft, these holes leading to the connecting-rod bearings. The rod bearing holes register once every revolution with a hole in the upper portion of the connecting-rod bearing. This hole, however, communicates with the hollow connecting-rod, the diameter of the rod oil passage being 7-8 inch. This passage as will be seen from the end section view extends to the wrist pin which also receives the proper amount of oil. After the oil lubricates the pin it makes its way to the sleeves, oils them and then drops to the bottom, spraying as it leaves the lower portion.

Governor Controls Oil Pressure

The oil pressure varies with the speed of the motor the extent of the flow being controlled by an automatic governor interconnected with the throttle. This governor has a three-way cock which receives the oil before it is sent to the various parts. The governor openings are graduated so that with fully opened throttle the path is unrestricted, with closed throttle the discharge from the cock is back to the sump allowing little to go on its rounds and at intermediate throttle openings the flow is in proportion.

The Moline engine uses Bosch Duplex ignition, and a Schebler carbureter. The magneto sprocket acts as a means of adjusting the chains used in the motor. This is done by swinging the instrument on a pin pivot shown in an illustration herewith and thus chain slack may be taken up.

Cone Clutch Continued

The new series Moline uses the same clutch as was used in the older model, it being a cone, but this season with two universals between it and the new four-speed gearset instead of one. The change-speed lever is nearer the driver and a neater mounting is provided. From the gearset back the drive is through shaft to the new floating spiral bevel axle. Aside from the change in gear types the axle is as before.

The semi-elliptic, 60-inch rear springs placed under the axle housing are unchanged. Wheels carry 36 by 4 1-2 inch tires and wire wheels of the same size may be had at $90 additional cost. Left drive and center control are retained.

Wagner Cranking and Lighting

The cranking and lighting equipment of this car consists of the Wagner two-unit, 12-volt type with the generator mounted on the left of the motor directly below the magneto. The cranking motor is on the opposite side under one of the motor supports. The drive is direct through a pinion on the motor shaft and toothed flywheel. Initially a current of about 220 amperes is needed by the cranking motor but as soon as crankshaft rotation begins there is a drop to about 75 amperes. Current is furnished by an LBA battery under the front seat. Operation of the cranker is by a lever placed next to the gearshift lever and distinguished from it principally by its length, which is less than that of the gearshift control.

New Roadster Design

The touring body of the new series is practically the same as those of the preceding series, but with little refinements hardly perceptible, and yet thought necessary by the maker. The roadster body is one of unusual design, due to the generous curves of the lines. The rear deck is large enough to accommodate two tires and any amount of tools and baggage, a novel arrangement being a door on either side of the deck and one at the rear, the latter being used for tires and the former for baggage, etc. The cowl, hood and rounded-top radiator are well blended.

The touring car presents almost the same appearance as the roadster from the windshield forward. The touring body is of clean design with a bell back clean boards, and in a word is up to the minute.

Nothing is lacking in the matter of equipment, and among the features aside from the new tire pump may be mentioned, a one-man top, Hartford shock absorbers, electric horn, clock, and trouble lamp.

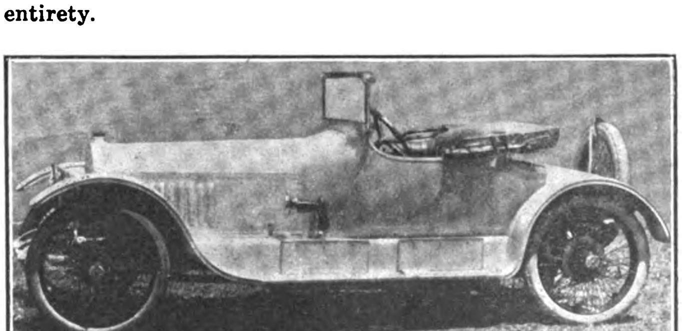
The standard painting is blue black, but with three weeks notice the Moline company will do a special job at $30 additional. If the body alone is to be special only $20 is charged, and if the hood, fenders, etc., are to be colored differently, $10 extra is asked.

New Body on Doble Steam Roadster

A refined type of body has now been fitted to the steam roadster developed by the Abner Doble Co., Waltham, Mass. This car was completely described in THE AUTOMOBILE for April 9, 1914. It is featured by the fact that a honeycomb type of radiator is successfully used as a condenser, doing away with the difficulty experienced in previous steam engines in having to stop frequently for a renewal of the water supply. The car has a 25-horsepower engine geared, 1 to 1, and is capable of developing 75 miles per hour without showing any exhaust steam. At this gear ratio the car is capable of obtaining a speed of 60 miles an hour from a standing start in 15 seconds. The engine is a four by six single expansion, double acting type and has a Stanley tire tube boiler.

Combination Rubber Takes Over Keaton Tire

NEW YORK CITY, Sept. 15—The Keaton Tire & Rubber Co. has been taken over by the Combination Rubber Mfg. Co., this city, which will continue the manufacture of special brand tires and tubes, and take over the business in its entirety.



Finished roadster body on the Doble steam chassis

Initiative Vs. Imitation

NOW that the eight-cylinder motor has become a reality as a component of stock cars in America it is to be hoped that there will not be a needless stampede from four-cylinder and six-cylinder construction to this latest factor in motor design.

Everybody was glad that after the single-cylinder motor the twin made its appearance; there was equal satisfaction when the four displaced the twin; a few years ago the rise of the six played its part in the rôle of evolving the eventual motor, or, at least, bringing us more in line with the course that leads to the eventual goal; and today the advent of the eight cannot but play its part in carrying the history of internal combustion progress nearer the end.

The days of the four-cylinder motor as a factor in the automobile world are far from numbered; the six-cylinder design is yet distant from its final stages of perfection; the eight is but in its swaddling garments.

There is a field for all, and initiative rather than blind imitation should be the watchword of many concerns. The superior advantages of the eight-cylinder over the six cannot be denied any more than those of the six-cylinder over the four-cylinder, or the four in turn over the two.

There are many other factors in the eight; its simple crankshaft, its short length compared with the six, the ability of the engineer to incorporate in it many of the factors that have been developed in the production of the present counter-balanced, high-speed, high-efficiency four; and against these are more valves, more valve parts and some factors.

One of our greatest builders set out a decade ago to develop a four-cylinder car and today he is the biggest producer in the world. Sixes have come, but with him it has been the working out of his own conception of what a rational motor car should be.

Let us have more of this stalwart individuality, an individuality, which between the lines, tells of a careful analysis of conditions as seen at the present and coupled with a sane survey of the factors that play their part in framing the future.

It takes backbone to map out any policy of individuality, in face of great odds. But sane individuality always will succeed, provided the three essentials of success are in the proposition: First, that you have a motor that has merit in it; second, that you have the men to design and manufacture and sell it; and, lastly, that the money is at hand to carry the organization along.

The eight has its broad and peculiar merits; so has the six, so has the developed high-efficiency four; let us have them all, until such time when the continued development of each to more nearly its maximum perfection is accomplished.

WE DO NOT WANT STAMPEDING, BUT WE WANT A DEVELOPMENT OF ALL TO ACCURATELY WEIGH THEIR RESPECTIVE MERITS AND DEMERITS.

The Wake of War

THE commercial vehicle is bound to develop more as a result of the present war than the passenger vehicle industry. There is today a staggering destruction of motor trucks of all kinds and also of horses in the war. With the closing of hostilities business will demand a replacement of these. Merchandise will have to be moved. Europe must have trucks. Many of her railroads will be more or less out of commission for a year, as their bridges are gone, their road bed destroyed in places and much of the rolling stock crippled.

In the cities the scarcity of horses will make itself conspicuous, and it will be at a high price that horses can be secured. The motor truck maker then will have his opportunity. He must have his vehicle ready, and he must be ready to meet the terms of the people. The American truck builder desirous of getting into the European market, and it is worth while, if for no other reason than the enormous field Russia offers, must be ready to meet long-term finance that is sure to follow in the wake of the war. Time payments up to 2 years will not be abnormal.

European factories in the majority of instances are already so disrupted that it will take 6 months or a year to get well re-organized. Much new help will have to be taken on, to fill the places of those who went to the front but never returned. American makers have a fighting chance, but they must be ready with the goods and with the business arrangements.

Trucks and Horses Destroyed by War

Tradesmen Back from Europe See Commercial Vehicle Boom for American Manufactories—Will Replace Railroads Temporarily

NEW YORK CITY, Sept. 15—John A. Olt, director of the export department of the Hudson Motor Car Co., one of last week's arrivals from Paris, where he has been for the past 14 months in the interest of the Hudson export trade to Continental Europe, looks for a heavy demand for American cars after the cessation of hostilities. This will largely be due to the great numbers of motor cars and motor trucks that are being destroyed in the present campaign.

According to Mr. Olt, everything is carried on with an unprecedented rush in military circles. Drivers do not stop to lubricate and give proper attention to their cars, so that up to September 4, the date of Mr. Olt's departure from Paris, as many cars were being abandoned in the war zone due to the carelessness of drivers as to mechanical difficulties. As soon as a car is incapacitated in this way it is generally destroyed, particularly when the army is retreating. What is needed today in France is more drivers rather than cars.

Trucks Will Replace Railroad

The need of cars after the war is over will be due to a variety of causes: First, many of the railroads are being destroyed and the roadbeds torn up. It will be months before these are repaired and in the meantime freight will have to be moved so that the demand for commercial vehicles will be particularly great. Second, due to the great slaughter in horses there will be a shortage in many of the industries after the war, and in many cases motor trucks will be called for. There should be a big market for a small capacity vehicle.

In the passenger car field many of the wealthier classes will undoubtedly want to purchase cars immediately after the war is over due to the fact that they have donated one or two of their machines for military use and where these are destroyed they will naturally purchase new ones.

Long Credits Necessary

Mr. Olt contends that the determining factor in American export business after the war will naturally revolve on the question of long credits and finance. The European buyers are educated in purchasing on time extending from 6 months to 2 years, and American exporters will undoubtedly have to revamp their European selling policy more or less in accord with these time-payment methods.

Few sales can be expected from the prosperous business man in Paris worth $50,000 or under. This class learned the terrible lesson of thrift after the war of 1870 and it is certain that the present war will not change their characteristics but rather tend to make them hoard still more. In commercial vehicles it will be different as industries will demand these and Americans should be in a position to profit by it.

Many exporting houses pulled in all of their European representatives as soon as the war situation became acute, which policy can only be considered as a mistake. Neutral countries are today asking for American cars and their confidence in those companies that have temporarily discontinued their representation will be considerably reduced. Europe is learning more and more the lesson that America has good cars. This war will temporarily set matters back but it remains with American makers to keep close to the European situation.

Mr. Olt says that Hudson cars, except those in the possession of owners, have not been commandeered by the government. There are several of them, however at the front, one being used by Capt. Rawlinson, a former Indian officer, but now in the service of Sir John French, commanding the British troops. This is the car that was to have participated in the Isle of Man races last June but which was disabled the day previous to the races.

To Organize National Dealers Association

MINNEAPOLIS, MINN., Sept. 12—It is the purpose of the Retail Automobile Dealers Association, of the Northwest, which has just held a 2-days' convention here, to have the organization become the National Retail Automobile Dealers Association.

Organized in 1913 as a state organization its officers have broadened its field and have made it a Northwestern association, including among its members the dealers from the Dakotas, Wisconsin, Iowa, Montana, and, of course, those of Minnesota.

The principal object of the association is to bring about the standardization of the automobile business through closer co-operation among the dealers, by education of the dealers on the matters which do not promote their interests but rather harm them. It appears from what one of the speakers at the convention said that many dealers still consider the automobile business as a little "game" instead of a serious business proposition.

The association will work especially to bring about the elimination of abuses and malpractices, such as the selling of cars at different prices when there should be only one price, or the selling of a car at the old price in one place and at the new cut-price in another place, the very same day the announcement of the new price has appeared. An effort will be made to convince the automobile manufacturers that it is not a good policy to announce their new models months before they can actually start to supply them. It will also be one of the objects of the association to urge the manufacturers to see to it that at local shows, or state fairs, only the new models are exhibited, and not old models which, however, might lead people to think that they are the new ones.

Trade Data Wanted By English Makers

NEW YORK CITY, Sept. 15—The dependence of Europe on the United States for automobiles and supplies in the present crisis is shown in a letter received today by THE AUTOMOBILE from Critchley, Evans & Co., London, signed by S. E. Barlow of that firm.

Mr. Barlow asks THE AUTOMOBILE to interest the American trade in sending catalogues and descriptive matter to his firm if the trade are desirous of supplying English makers with material. His letter reads:

"Owing to the present European crisis there is a state of temporary stagnation in the pleasure car section of the motor trade, but on the other hand the commercial vehicle makers are exceptionally busy owing to the large orders given to them by the War office.

"While in the pleasure car section there is sure to be a falling off in the demand during the period of war there is every reason to believe that soon after the declaration of peace the motor trade will become very brisk in this country, not only in the commercial vehicle section but also in the pleasure car section.

"Continental supplies of material are entirely stopped and the automobile firms in this country have to look for supplies of material to manufacturers at home. What effect the war will have as regards Continental supplies of material to this country is difficult to say at the present moment. The fact is that British motor firms will have to look for their supplies in this country, and may also be tempted to go to America. Now, therefore, is the time for American firms to do business here if they are able and willing to do it.

"Needless to say we are in as good a position if not better than most firms connected with the motor trade for introducing new sources of supply, particularly if they are of excellent repute. We have done a huge trade for continental manufacturers which has, of course, suddenly ceased.

"We shall be glad if you will get into touch with the large American suppliers of automobile material of all descriptions, and ask them to be good enough to communicate with us as soon as possible, sending catalogues and all descriptive matter together with full information relative to their capacity and ability to supply firms here, if they are willing to do the business. Standardization of parts has only been adopted on an insignificant scale here and it is a question in the majority of cases of supplying material to meet English automobile makers' individual requirements.

"Owing to the great changes which are bound to come over the whole course of commerce in Europe, it is necessary to consider all possible sources of supply. We shall be glad therefore if you will ask suppliers to write to us direct giving us full information as soon as possible.

"We are interested in everything appertaining to the automobile trade. There must be a large number of firms requiring representatives here for the sale of accessories to wholesale and retail houses."

L. B. Kilbourne's $350 Taxi Ride

NEW YORK CITY, Sept. 12—L. B. Kilbourne, Chicago, Ill., financial partner with Chas. Y. Knight in the firm of Knight & Kilbourne, owners of the Knight sleeve valve motor patents, returned today on the *Campania* from a 3 months' visit in Europe, the last month of which was spent in Germany. One week of this month preceded the opening of war, followed by the first 3 weeks of the war. This time was spent in Baden in the southern part of Germany, and during the last week in August Mr. Kilbourne, in order to get out of the country, had to travel by taxicab from Baden up the Rhine valley to the Dutch frontier where he took a train to Flushing and thence by boat to England.

Mr. Kilbourne's taxicab ride, which cost him $350.00, is representative of the many experiences that American tourists have been through due to the European war. Practically an entire month was spent at Baden before a solution was arrived at as to how to get out of the place. Mr. Kilbourne and his party had arrived at Baden after a 1,600-mile tour through France and Switzerland, getting into Germany the day mobilization started. At that time he was on the Swiss-German frontier and was compelled to register himself, party, and chauffeur, with the German police authorities before he could proceed in his car from village to village. After this registration, and securing military passports, he toured to Baden, where 3 weeks were spent. It was impossible to leave this place with his car, which is still held there, and where his English chauffeur also remains as a prisoner of war. For the present, the chauffeur is permitted to live in the hotel where he is given the freedom of the town, but where he must pay his own bills. Should he not be able to do this he would be dispatched with other prisoners of war to some impounding depot.

Mr. Kilbourne's taxicab ride from Baden to the Dutch frontier was the only means of getting out. He was charged 1 mark, or approximately 25 cents a mile, and had to pay this sum for the out trip as well as the return trip. This one-way trip of 400 miles was up the Rhine valley, some of it through country over which the German troops had passed in their march to the front. The taxicab was not disturbed on its trip excepting being stopped at every village, town and city to show the necessary passport to the soldiers guarding these places. Every bridge was guarded by soldiers and here the transports had to be shown.

When passing through Coblentz, Mr. Kilbourne passed within a few yards of the castle where the German Emperor with his suite were stopping at that time. It was about 5:30 in the afternoon and the population of the city was on the street waiting for the Emperor to leave in his train of fifty motor cars which were drawn up in front of the castle. These cars represented every type of vehicle necessary for the Emperor and his staff, and included kitchen cars, sleeping vehicles, office quarters, etc. With such a motor equipment it would be possible for the Emperor to move his headquarters according to convenience and entirely independent of railroads.

Throughout the Rhine valley conditions seemed normal. The crops in the vineyards were being looked after, it being apparent that those needed to harvest the grapes and other products were left behind. Business seemed about as usual in many of the towns passed through, excepting Frankfort, the big financial center, where there was a greater air of dullness. Stores were open in all of the places, but theatres and other places of amusement entirely closed. In many places large forces of reservists were being trained in military camps.

The roads were practically deserted by motor cars excepting those used by officers of the different regiments, which were constantly moving about. These are all passenger cars of all types, and have the number of the regiment printed in large figures on the bonnet similar to the numbers on a racing car in a contest.

When traversing those stretches of road over which the army had passed, there were few evidences of military activity. These were largely confined to huge piles of empty tins by the roadside, these having been filled with food for the soldiers. At other places there were evidences of night encampments of cavalry.

Motor cars and horses are most in demand at present, and present indications would show that there will be a tremendous demand for motor trucks after the war is over because of the large number of horses that have been destroyed, these horses having in many cases been taken out of industrial fields which must be either supplied by more horses or motor trucks. There will also be an increased demand for motor trucks because of the large destruction of them that is taking place in the movements of the armies. This is largely due to the forced retreat, first of the allies, and later of the Germans. In these forced retreats whenever motor vehicles break down they are totally destroyed by a charge of explosive, rather than being left to fall into the hands of the enemy. This destruction means a heavy reduction in the number of vehicles in commission, and it is natural to expect that many of these vehicles will have to be replaced when the war is over.

When in England, Mr. Kilbourne visited the plant of the Daimler Co., Coventry, which plant has been working at full capacity since the declaration of war. Upwards of 100 workmen have been taken from the factory to join the colors, but others have taken their places. The factories have been working at capacity schedule on the 3.5 ton subsidized chassis and also on the 20 horsepower passenger car, which chassis seems specially suited for officers.

At present there is an enormous demand in England for magnetos, due to the fact that the English makers were great users of Bosch goods, which it is now impossible to receive from Germany. Already some English manufacturers have begun overtures with American magneto makers.

Patriot Presents Chandler Stock to Denmark

CLEVELAND, O., Sept. 10—The Chandler Motor Car Co., has received a letter from its Denmark distributors, Messrs. Mammen & Drescher, who are located in Copenhagen, which partly reads, as follows: "We have not a single car on hand as one of our wealthy patrons on learning that our Danish army was rather short on motor cars, bought our entire stock of sixes and presented them as a free gift to the government. If our stock had been larger he would have taken more cars. We are now entirely without your cars and wish you to rush our orders for immediate delivery."

In speaking about its foreign business, vice-president and sales manager C. A. Emise of the Chandler company said: "Our export business has already materially increased. Nearly every one of our foreign dealers outside of the war zone increased their orders for immediate delivery and we are at present enjoying a larger export business than at any time in our history."

For Uniform Automobile Laws in N. J.

TRENTON, N. J., Sept. 15—With the selection of Job H. Lippincott, commissioner of motor vehicles, as chairman, the commission named by Governor Fielder to consider municipal ordinances governing automobile traffic is completed. The commission adopted a resolution which outlined the scope of the work. It will examine the motor vehicle laws of every municipality with a view to the preparation of a model ordinance.

Briscoe Reduces Roadster Price to $785

JACKSON, MICH., Sept. 14—The Briscoe Motor Co. has reduced the price of its roadster to $785, completely equipped, instead of remaining at $900, as announced in THE AUTOMOBILE of September 10, page 513. The price of the touring car is also $785.

Benz Takes Over KisselKar for N. Y. City

NEW YORK CITY, Sept. 14—KisselKars and KisselKar trucks will be handled at retail in this city by the Benz Automobile Corp., which has taken over the salesrooms of the Kissel Motor Car Co., at 1696 Broadway with the agency.

C. H. McCausland, who has conducted the Kissel retail as well as Eastern wholesale business from 1696 Broadway, will continue as district manager, retaining his office at the same address. His territory will include, as before, the states of New York, Connecticut, New Jersey and Eastern Pennsylvania.

Big Program for Truck Convention

Industry to Be Enlightened in the Best Ways to Build, Sell, Drive and Maintain Commercial Vehicles at 4-Day Detroit Congress Beginning October 7

DETROIT, MICH., Sept. 11—The motor truck convention to be held in this city on October 7, 8, 9, and 10, gives promise of being one of the greatest motor truck conventions ever held in America. The work of drafting the program for the 4 days was practically completed last week, but as yet definite announcements giving the names of the people who will present the different papers cannot be made until the acceptances from these people have been received.

The program for the 4 days is particularly exhaustive and has been drafted with the object of taking up questions of direct value to the truck maker, the truck dealer and the truck owner. These questions are on pertinent subjects rather than academic.

The opening of the convention on Wednesday afternoon will be given over exclusively to manufacturers when subjects of direct value to them will be handled.

Thursday will have forenoon and afternoon sessions on subjects which concern both manufacturer and dealer.

Friday will be dealers' day and will be largely given over to questions of truck guarantees and service that manufacturers and dealers should give. These questions will be handled by representatives of the manufacturers and also dealers. Many dealers have been invited to come specially prepared to participate in the discussion.

Saturday forenoon will be clean-up session on subjects that have not been completed during the 3 previous days. There will also be a discussion of pertinent business subjects such as the necessity for dealers' organizations, the desirability of some form of motor truck exhibitions and other questions that may be brought up.

Although the exact order of the program cannot be given many of the subjects are now definitely decided upon.

The Trading Evil a Topic

"The Trading Evil" will be handled by one or two makers and several dealers. This is considered one of the most pertinent topics and in a canvass made of several hundred dealers, this subject is paramount with them. Dealers have been allowing too liberally on used trucks. The object of the paper and the discussions will be to show how this evil can be reduced, as well as offer means for making this business more profitable to the dealer.

"Evils from Overloading and Overspeeding and Avoiding Too Heavy Bodies" is a subject to be discussed. Manufacturers, dealers and body makers have been invited to prepare short symposiums on different aspects of this question. Axle and spring manufacturers have also been invited to participate.

"Used-Truck Market Reports" has been listed as a subject. The recent "Used-Car Central Market Reports" published by the Chicago Automobile Trade Association has resulted in the suggestion that similar reports be arranged for the motor truck field. It is believed that such would be of value and would serve as a guide to the dealer who is not familiar with value of used trucks.

"Traffic Engineering" will be handled by at least two experts in this line. Their papers will tell how the dealer can improve his conditions in this way.

"How to Calculate Costs," a question many manufacturers and dealers are asking themselves, will be analyzed in special papers by at least three traffic engineers who specialize in this work. Their papers will be direct and valuable, so that much of the information given can be applied at once by the dealer. Many dealers have been invited to supplement these papers by their own experiences.

Shall Trucks Be Sold on Terms

There are few questions that have been more widely discussed during the past 2 years than that of "Time Payments on Trucks." One professional financier who specializes on this work has been invited to outline his method. A leading manufacturer who sells direct on time payments will outline and defend this scheme. Makers and dealers who are opposed to this method of selling have been invited to prepare short papers for discussion.

"Territorial Lines for Dealers" will be handled by two or three makers. There is a movement to restrict dealers' territories and demand more intensified selling efforts. This aspect of the question will be discussed. The problem of carrying adequate supply of parts for trucks sold is one that enters into this topic.

"Tires for Motor Trucks" will be one department of the convention to be handled by four of the leading truck manufacturers who have been invited to prepare papers specially for the benefit of makers and dealers. They have been allotted different aspects of the tire questions.

One manufacturer has agreed to present a paper entitled "Parts to Be Carried in Stock by Dealers." His paper will go into the many ramifications of this subject.

It is expected that the question of "Manufacturers' Guarantee and Service" will occupy all of the Friday morning program. This is a question for manufacturers and dealers and will be handled by a leading truck maker and also by a leading dealer. Many dealers have been invited to participate in the discussion.

There are many other subjects that will be brought up, among which are:

"Loading Devices—Their Merits and Shortcomings."

"Driver's Influence on Successful Operation."

"How Manufacturer Can Co-operate with Dealer in Advertising."

"The Export Business; Best Fields and How to Develop Them."

"Motor Truck on the Farm."

It is expected that in a matter of 1 week the complete program for each day, with those handling the different subjects, will be announced.

Already the local committee here has made active progress. Headquarters and all convention sessions will be in Hotel Cadillac. The pleasure of those attending the convention is being well looked after. On Wednesday there will be a Dutch lunch with cabaret. Thursday evening the Detroit committee will tender a theatre party to all delegates. On Friday evening the official banquet will take place. Two or three well-known public speakers will attend.

Horses Twice as Dangerous as Automobiles in Chicago

CHICAGO, Sept. 15—As a part of street traffic, the automobile is safer for the pedestrian than the horse. Peter M. Hoffman, Coroner of Cook County, Ill., sets forth this fact in his biennial report on the deaths due to accidental causes in the city of Chicago, and its environs, for the year 1913. For each 5,000,000 miles traveled by motor vehicles there were 12.6 accidents as against 26.55 for horse-drawn vehicles.

In the city of Chicago and its environs, according to the report, there are 37,406 power vehicles and 65,118 horse-drawn vehicles. The daily individual mileage of these is forty-two and twelve respectively. Each day the total mileage of these vehicles collectively, is 1,571,052 miles for motor cars as against 781,416 miles for horse-drawn conveyances, or about twice as many miles for the automobile. Yet for the past 4 years accidents due to horse-drawn vehicles have averaged 4.15 daily while those due to motor cars have been 3.96.

It is clear that comparisons made as to the relative danger between horse vehicles and motor vehicles must be estimated on efficiency, and the number of miles traveled is the only rational basis on which to calculate. Therefore, in spite of their greater speed, automobiles are apparently under greater control in cases of emergency than any other form of street traffic.

Less Killed by Autos than Street Cars

Comparisons with street cars are also favorable. Of the total number of persons killed by accident in Chicago, 2.4, or 136 were traceable to automobiles, as against 2.92 or 165 by street cars. These out of an entire total of 5,648. In 1912 and 1913 automobile accidents as a cause of death were in tenth place on the Coroner's list, while street car accidents occupied sixth and eighth places respectively in those years.

If those who merely take the round figures in automobile accidents, in Chicago, for instance, 16 deaths in 1907, 18 in 1908, 28 in 1909, 52 in 1910, 75 in 1911, 98 in 1912 and 136 in 1913, would also consider the vast mileage being made by these freight and passenger vehicles, together with the decrease in horse vehicles and the corresponding increase in the number of power vehicles, they would get a true idea of real facts and relationships involved.

The blame for 50 per cent. of all automobile accidents may be placed upon the shoulders of the pedestrians who are injured. Safety First committees are beginning to realize this, and are making great efforts to educate the public to the necessity of looking out for themselves. Of course, to safeguard all concerned, the final solution of the automobile situation in all cities must rest in great part upon the competency and efficiency of the drivers, and this problem will no doubt be gradually worked out in more or less the same way as that of locomotive engineers, who, after having been trained in the shops as firemen and proved themselves competent are granted a license and given charge of an engine.

All Should Be Licensed

At the present time, in many of the states, only hired chauffeurs are required to have licenses, whereas owners of automobiles, their sons, daughters and relatives are permitted to drive their cars at liberty through the streets without licenses. It is from this latter class of people that most accidents are reported. About 6 months ago in New York City, a girl, whose father had just bought an automobile for her, and which she had driven for a short time on one occasion, killed two people and injured three others, when she became confused and drove her car on the sidewalk. Had it been necessary for this girl to obtain a driver's license prior to her taking out her own car, this accident would never have occurred.

Motorists as a rule drive carefully. This is shown by the small number of collisions between machines. When traffic from side streets is considered, this is quite an item. Pedestrians confuse motorists many times by wavering as to which side of the street they will run when they see an automobile approaching them. If pedestrians when standing in the middle of the street were to indicate to an approaching motorist on which side to pass them, and stand where they were, accidents of the kind would be reduced to a minimum.

Even under present statistics the streets are more safe from accident than the home. Falls, over 90 per cent. of which take place in the house, are among the leading causes of accident. It would therefore seem that while the streets are not entirely free from risk, it would be well to take into consideration that the constant attention and publicity which they call forth are making them more safe every year, while other causes of serious injury and fatality are overlooked.

E. V. A. A. Now Has St. Louis Section

ST. LOUIS, MO., Sept. 11—A St. Louis section of the Electric Vehicle Association of America has been organized. C. E. Mitchell, of the Union Electric Light & Power Co., has been elected chairman; F. E. Stevens, of the Stevens-Waverly Auto Co., vice-chairman; H. V. Marshall, of the Exide Battery Depots, Indiana, secretary. Other members are: Ralph R. Doak, Woods Electric Vehicle Co.; Louis Goodhart, Milton B. Strauss and Dwight B. Blossom, of the Electric Garage and Service Co.; Harry S. Turner, Mississippi Valley Automobile Co.; C. A. Irving, Rauch & Lang Garage; Harold G. Brouster, Rauch & Lang, St. Louis Co.; Dr. Melcher Ekstromer, General Motors Truck Co.

Crude Rubber Prices Normal—Due to British Control of Sea

NEW YORK CITY, Sept. 16—"The prices of crude rubber in America are practically normal and will remain normal, so long as Great Britain retains control of the seas so that shipments of plantation rubber from Ceylon can reach New York without interference."

This sums up the present crude rubber situation as expressed today by Thos. L. Robinson, president of the Republic Rubber Co., Youngstown, O., who returned yesterday from a month's trip to England where he had occasion to make a close analysis of the crude rubber situation.

One of the most salutory conditions observed by Mr. Robinson so far as the crude rubber supply for America is concerned, is that the British rubber brokers have diverted shipments of crude from Ceylon direct to New York and have further arranged that the shippers will draw on New York direct for payment, thus leaving London and the matter of high exchange out of the transaction entirely.

Mr. Robinson thinks that there was genuine reason for the panic in American prices of crude rubber a month ago, when the war first broke out, because for a period of 2 weeks no one knew whether Great Britain had complete control of the high seas and whether shipments of rubber from the East could be counted upon. Two weeks from the declaration of war England had demonstrated her control of the high seas and immediately the uneasiness in the market ceased. The prices of crude rubber did not increase in England while they were doubling in price in New York. The feeling is general that the price of plantation crude will rather decrease than increase.

Large Mileage from 7-Inch Tires

One of the interesting aspects of the tire industry in England as observed by Mr. Robinson is the extended use of 7-inch Palmer cord tires used on such large cars as Rolls-Royce, Sheffield-Simplex and Daimler. These tires are inflated to a pressure of 110 to 125 pounds and are actually giving as high as 30,000 miles road service. The only seeming objection to them is that the high inflation pressure makes for vibration, which is not desirable. Practically all of the cars of this type are using such tires. The cost is approximately 25 per cent. over standard sizes.

At the present time the Dunlop Tire Co. in England is practically under the government control in that the government has first demand on all tire supplies. The factory is particularly busy in contrast with many of the Continental factories which have been compelled to shut down because of war conditions.

At present there are being used in Great Britain a great many steel-studded pneumatics and throughout the country are billboards advising customers to put the steel studded tire on the right rear. In America this type of tire has a very restricted following but English motorists seem to prefer it.

Wants U. S. Dollar as Exchange Basis in S. A.

NEW YORK CITY, Sept. 16—That the business men of the United States in their South American trade, have been under a handicap of from 1 1-2 to 2 per cent. each way, by reason of the expense of making payments through London, is claimed by John E. Gardin, vice-president of the National City Bank.

When asked as to the possibility of providing for direct exchange in dollars and cents, as against the present system of payment through London in pounds, shillings and pence, Mr. Gardin states that there are two factors which will enter into the establishment of a system of direct exchange in dollars between the United States and South America, namely the establishment of branches of national banks such as are permitted by the Federal reserve act, also the increase of trade with South America.

$2,870,188,575 Business Done by S. A. Countries

NEW YORK CITY, Sept. 15—The twenty Latin-American countries of Central and South America conducted in 1913 a foreign commerce valued approximately at $3,000,000,000, the exact total being $2,870,188,575. Of this total the imports were valued at $1,304,261,736 and the exports at $1,565,916,812.

Argentina, Brazil and Chili are three of the biggest importers of American goods, especially in automobiles. Brazil did a 1913 business of $795,754 from this country, its total being $4,684,069. Automobile accessories from the United States also formed a large part of its imports, amounting to $104,118, out of a total business of $534,850.

MILWAUKEE, WIS., Sept. 15—The Kissel Motor Car Co., Hartford, Wis., and the Chas. Abresch Co., Milwaukee, last week shipped fifty truck chassis and bodies to Greece for delivery to the Greek government. The bodies are regular express bodies with canopies and the chassis are of the 2 1-2-ton type.

NEW YORK CITY, Sept. 14—J. T. Ranier and P. N. Lineberger have severed their connection with the R. & L. Co., Inc., of New York City, metropolitan dealers for the Garford and Willys-Utility trucks. They have opened a temporary office at 299 Madison avenue, this city, and expect to sell automobiles and commercial vehicles.

July Exports Declined; 1914 Total $1,000,000 Less

WASHINGTON, D. C., Sept. 17—*Special Telegram*—In July, 1,315 motor cars valued at $1,249,819 were shipped abroad. During the seven months ending in July, a total of 18,942 cars valued at $16,818,422 were exported.

This shows a considerable falling off for the month. The previous month saw 2,072 cars valued at $1,991,139 sold abroad, while during July of last year 1,764 automobiles, selling for $1,736,253, were sent out of the country.

More cars have been exported during the first 7 months of this year than were shipped abroad during the corresponding period last year, but the value is less. Last year the number of cars was 17,190 as against 18,942 this year, and the value was $17,760,733 as compared to $16,818,422. This indicates an increase in the popularity of the low-priced American car.

Rubber Goods Mfg. Co. Declares Dividend

NEW YORK CITY, Sept. 11—The Rubber Goods Mfg. Co. has declared the regular quarterly dividend of 1 3-4 per cent. on the preferred stock and a dividend of 2 per cent. on the common stock, both payable September 16 to stockholders of record, September 12.

NEW YORK CITY, Sept. 11—The Kelly-Springfield Tire Co. has declared the regular quarterly dividend of 1 1-2 per cent. on the 6 per cent. preferred stock and 1 3-4 per cent. on the 7 per cent. second preferred stock. The dividends are payable on October 1 to stock of record, September 15.

Registrations in N. Y. State Number 161,353

NEW YORK CITY, Sept. 14—$1,462,963.86 has been paid to New York State up to September 8, in fees for the registration of motor vehicles and chauffeurs' licenses. This is nearly $200,000 in excess of the amount contributed for the same purpose during the whole of last year.

Up to the above date, 161,353 motor vehicles have been registered. This is an increase of 36,090 over the corresponding period last year. The number of chauffeurs licensed is 61,398. During all of last year there were registered only 132,450 motor vehicles and 56,702 chauffeurs licensed.

Market Reports for the Week

This week's markets were in general more quiet and steady. The changes that occurred were the usual ones. Tin declined $1.62 per 100 pounds. There were several small sales of spot. About 3,500 tons of tin are available for September delivery. Copper was quiet and steady. More small sales of electrolytic made this week to domestic consumers, were reported. The exports of copper to Europe since September 1 were at the rate of 18,000 tons for the month. Lead rose $0.15 per 100 pounds. There is a fair demand for this metal. The crude rubber market is easier with Up-River Fine at $0.68, with no sales of any consequence noted. Shipments of rubber are coming in regularly from the various foreign ports.

Ajax-Grieb Fiscal Year Greatest in History

NEW YORK CITY, Sept. 10—With the close of August the fiscal year of the Ajax-Grieb Rubber Co. came to an end, showing a greater volume of business done than ever before in the history of the company. This, despite the fact that in November there was a 28 per cent. decrease in tire prices, a difference which had to be made up before any gain could be shown. Furthermore, the Ajax was one concern not to make any advance in prices when the European war began. It has not yet announced any such new schedule, and will not as long as its supply of crude rubber, bought at before-the-war prices, lasts.

A 10 Per Cent. Pope Creditors' Dividend

HARTFORD, CONN., Sept. 12—Judge Joseph P. Tuttle of the superior court issued an order this week authorizing Receiver Colonel George Pope, of the Pope Mfg. Co., to pay a dividend of 10 per cent. on the claims allowed. The receiver represents that he has sufficient funds to pay a 10 per cent. dividend on disallowed claims if they are eventually allowed. Receiver Pope has been authorized to turn over to the Massachusetts receiver old bicycles and tricycles which made up the Pope museum in this city. The allowed claims aggregate approximately $1,600,000.

In the United States court at Boston Pope claims to the extent of $1,641,382 have been allowed. The allowed claims include those of the noteholders. Claims to the extent of $157,365 are to be referred to a master and included in these are the claims of the officers of the Pope company, $44,537 for Albert L. Pope, $30,153 for Charles E. Walker, and $26,802 for Wilbur C. Walker.

No offer has been made yet for the Massachusetts property at an upset price.

Heavy Printed China Duty for Plug Porcelains

NEW YORK CITY, Sept. 15—The Champion Ignition Co., Detroit, Mich., lost in a protest over the rate on porcelain insulators for spark plugs. The insulators had printed letters and numbers on their fronts, and for this reason the customs collector classified them as printed china with duty at 55 per cent. The importer claimed that the lettering was merely to protect patent rights.

Reo Declares Extra 12½ Per Cent. Dividend

LANSING, MICH., Sept. 12—At a meeting of the stockholders of the Reo Motor Car Co., this city, R. C. Rueschaw, general sales manager, was elected to the board of directors. In addition to the regular quarterly dividend of 2 1-2 per cent., an extra dividend of 12 1-2 per cent. was declared, payable October 1, to all stockholders of record at the close of business September 20.

Seven More White Trucks for Post Office

WASHINGTON, D. C., Sept. 14—The Post Office Department has awarded contracts for seven trucks to the White Co., Cleveland, O. The capacities are as follows: Five 1,500-pound trucks at $2,050; one 3-ton truck, $3,445, and one 1.5-ton truck at $2,825. These seven, together with the twenty purchased from the White Co. a year ago, make a total of twenty-seven of these vehicles at present owned by the department. The twenty purchased a year ago are in use in postoffices in five or six different cities.

Knox Sells Five Tractors to Europe

NEW YORK, Sept. 16—Direct results of the European war on the motor truck business in America has been demonstrated this week when the Knox company sold five 5-ton tractors to one of the foreign governments. These tractors are being shipped this week. For the past week emissaries of other foreign governments have been in America looking for motor trucks. There seems to be a demand for approximately 650 trucks of from 2 5 to 3-ton capacity, these being practically on a par with the subsidized trucks in the majority of the European countries. In addition there is talk of buying 250 trailers with approximately 750 wagons to go with them. Other lines of merchandise being purchased include 6,000,000 horseshoes, 400,000 army blankets, and 100,000 horse blankets.

Ford's Home Trade Growing; Locates Four New Branches

Profit-Sharing Announcement Has So Boomed American Sales That War Constriction Has Not Been Felt

DETROIT, MICH., Sept. 10—Beginning October 1, there will be four new Ford branches in the United States, bringing the total number of branches up to forty-eight. These new branches will be located in Milwaukee, Wis., 143 Eighth street, A. W. L. Gilpin, manager; Newark, N. J., 1721 Halsey street, E. T. Baskett, manager; Charlotte, N. C., A. J. Langford, manager; and Brooklyn, N. Y., 1476 Bedford avenue, G. E. Hunt, manager.

Besides these forty-eight branches the Ford Motor Co. now has twenty-four assembling plants and 5,600 dealers in the United States. Including the whole world there are about 8,000 dealers. There are seventeen branches located in foreign lands and two Ford factories outside of America, these being the Walkersville, Canada, plant and the one in Manchester, England, where probably 15,000 cars are made now annually. This English plant supplies the British Isles only, that is, England, Ireland, Scotland and Wales.

The Ford plant in Walkerville, Ont., supplies the British colonies and the Canadian trade. Europe's requirements, excepting those for the British Isles, have been taken care of from the main plant here in Detroit.

While the exact figures are not given, it is safe to say that at least 10 per cent. of the 1914 output was shipped to Europe and this totals about 24,000 cars. To France alone at least 5,000 cars were shipped, and during May, according to H. P. White, continental manager, 500 cars were sold in France. The business in Russia figured at between 4,000 and 5,000 cars for the year. In most all other European countries the sales have been heavy this year.

Although the export trade to Europe is necessarily small at present, and will remain so for some time, there is no intention to cut down its proposed output of 300,000 cars for 1915. As a matter of fact, it is stated that since the profit-sharing scheme went into effect the demand has been so heavy that it will be somewhat difficult to supply all the dealers with the number of cars they desire.

200 Hupmobiles in New York Reunion

NEW YORK CITY, Sept. 15—More than 600 persons in nearly 200 Hupmobiles participated in a Hupmobile reunion which was promoted by Chas. E. Reiss, New York Hupmobile distributor, on Wednesday afternoon, September 9. The cars were formed in line at 130th street and Riverside Drive and, headed by Reiss in one of the new 1915 models, proceeded to the Hotel Shelburne, Coney Island. At the hotel Reiss' guests were lined up for a photographer, after which a banquet was served. Chas. E. Buck, assistant advertising manager of the Hupp Motor Car Co., acted as toastmaster. A tall silver Hupmobile cup, presented by Reiss for a dancing contest, was won by Dr. H. W. Taylor and Miss Nockler. Dr. Taylor has been a Hupmobile owner only about 6 months.

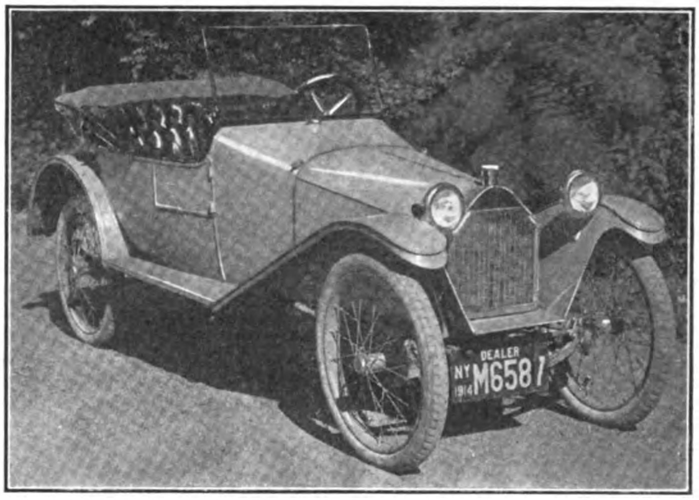
Pierce-Arrow Agents in Session

BUFFALO, N. Y., Sept. 15—The first annual convention of agents and salesmen of the Pierce-Arrow Motor Car Company opened here yesterday forenoon in the factory of the company in Elmwood avenue. About 60 agents and salesmen are in attendance at the meeting which continues until Wednesday evening. An interesting program has been arranged by the Pierce-Arrow people which includes considerable entertainment for the delegates.

Officers of the company will read interesting papers touching on the vital subjects of the day in the automobile industry. As the Pierce-Arrow factory is behind in its deliveries, causing a scarcity of cars, arrangements were made with the International Railway Company for a special car to transport delegates to and from the factory. After business hours two banquets, theater parties and various other entertainments were on the program.

Coffin Added to Patents Committee

NEW YORK CITY, Sept. 14—Howard E. Coffin, vice-president of the Hudson Motor Car Co., Detroit, Mich., has been appointed a member of the patents committee of the National Automobile Chamber of Commerce. With him on the committee are C. C. Hanch, Marmon, chairman; Wilfred C. Leland, Cadillac; Windsor T. White, White, and W. H. VanDervoort, Moline.



Remington roadster with electric equipment and automatic gearshift

New York Show Space Drawing, Oct. 8

NEW YORK CITY, Sept. 11—The National Automobile Chamber of Commerce has voted that the automobile shows in January shall be invitation affairs to which will be invited such concerns in the automobile and accessory industry as can be cared for properly.

Allotment of space will be confined to members of the N. A. C. C., to members of the Motor and Accessory Manufacturers, the Motor Cycle Manufacturers' Assn. and the Electric Vehicle Manufacturers' Assn., and to such other persons and companies as may be formally invited by the management to participate.

All applications for space must be in hand by October 3 to participate in the first allotment. The drawings for space for both shows will take place at the offices of the N. A. C. C. on October 8, in connection with the semi-annual meeting of that organization.

The show committee will again be George Pope, of the Pope company, W. C. Leland, of the Cadillac company, and H. O. Smith, of the Premier company.

The Chevrolet Motor Co., Flint, Mich., has been admitted to membership in the association. The N. A. C. C. now includes ninety-two automobile manufacturers.

TACOMA, WASH., Sept. 7—For the automobile exhibit at the Oregon State Fair at Salem, Ore., September 28 to October 3, space has been set aside to accommodate fifty cars. Both trucks and pleasure cars will be exihibited and it is expected this will bring numerous buyers from all parts of Central Oregon. The exhibit will be staged by Joseph M. Rieg.

New Small Velie Six at $1,595

NEW YORK CITY, Sept. 15—An entirely new small six selling at $1,595 and called the Biltwel series 15 is the feature of the line of the Velie Motor Vehicle Co., Moline, Ill., for the ensuing season. Last season's small four, the model 11 has been discontinued and the big six, called series 14 this year and the big four called series 12, have been improved and reduced in price. The four has been reduced, from $2,000 to $1,750, and the six from $2,350 to $2,015. New bodies are featured on all the cars. In the new small six the Velie company has incorporated a number of special features which have lately come into use by motor car builders. The spiral bevel rear axle gears is one of these features, the tapered frame, another.

Show Building for St. Louis Accessory Trade?

ST. LOUIS. MO., Sept. 10—At a dinner-meeting of the St. Louis Motor Accessory Trade Association, the Continental Auto Equipment Co., was elected a member of the association. T. L. Hausmann was appointed chairman of the show committee. There was a discussion concerning the securing of an auditorium for show purposes in St. Louis, just as one was obtained by the Kansas City and Denver dealers. There will be another meeting within a short time at which all interested in the automobile and accessory trade in this city will be asked to attend to give their views, so that active work may be started in the endeavor to secure an auditorium.

One Car in Every Twelfth Wisconsin Family

MILWAUKEE, WIS., Sept. 12—There are now fully 50,000 automobiles owned in the State of Wisconsin, 36 per cent. belonging to farmers and 64 per cent. owned in cities and towns.

According to the schedule of the assessors in forty-one counties considered the agricultural districts, and not including Milwaukee county, as the latter's city population represents 97 per cent. and the rural population only 3 per cent., it is shown that one farmer's family in every twenty-two owns an automobile, and the proportion is one to twelve for the city family. In Milwaukee county one in every fifteen farm families owns a motor car and one in every sixteen city families. In Walworth county, considered the richest, one farmer in every nine owns a car. In that county the average value of a farm is $13,000, while in Shawano countv the average value of a farm is only $6,000 and only one car is to be found to every thirty-seven farms.

Blair Co. to Make Trucks Only

NEWARK, OHIO, Sept. 10—Steps are being taken toward a complete reorganization of the Blair Mfg. Co., under the title of the Blair Motor Truck Co., which was recently chartered under the laws of Ohio. To facilitate the reorganization all of the assets of the concern have been deeded to Carl Norpell, trustee, for $15,000 and other considerations. The old concern will remain in business long enough to close up its affairs and dispose of its finished agricultural implements.

In the future the product will be restricted to motor trucks. The truck is equipped with a patent direct drive. A number of the old stockholders will be interested in the new corporation.

The company is now building a 5-ton double deck truck for passenger service in Philadelphia.

A $495 Car with Automatic Gearshift

NEW YORK CITY, Sept. 15—The Remington Motor Co. will manufacture a two-passenger roadster selling at $495, with electric lighting and starting and full equipment. An automatic gearshifting device is a feature of the car.

The car is built on conventional lines, but on a small scale, the wheelbase being 100 inches, the tread 42 inches and the weight between 750 and 800 pounds.

A four-cylinder L-head block-cast 2 3-4 by 4 1-2 motor is a unit with the three-speed gearset and the inverted cone clutch, the unit being on a three-point suspension. Lubrication is by splash with pump circulation, cooling by the usual method with circulating pump, and ignition by the Atwater Kent system with automatic spark advance.

Drive is through a propeller shaft with two leather universals, bevels and a four-pinion differential to the three-quarter floating rear axle. A pressed steel torque member is used. Wire wheels are regular equipment, but wood wheels will be furnished as an option. Tires are 28 by 3. The front spring is a transverse semi-elliptic and the rear springs three-quarter elliptics. Steering is by worm and sector gear, adjustable, with a 15-inch wheel. Service brakes are metal to metal, running in oil, consisting of two bands enclosed in the differential housing and adjustable from the outside; the emergency brakes are on the hubs in the usual way.

The equipment includes top, side curtains, windshield, speedometer, electric horn, electric starting and lighting system with headlight dimmers, and the usual tools. The body (only one style is built) is of steel with tapered hood and, in fact, big car lines throughout. The color is gray, with black striping.

The Remington Motor Co., this city, has opened offices and salesrooms at 2 Columbus Circle, and has completed arrangements for the erection of a factory at Rahway, N. J. A temporary factory has been secured for the production of the first lot of cars, which will be ready for delivery in November.

P. E. Remington is the moving spirit and vice-president of the company. B. B. Monypeny is president; J. T. Macgregor, treasurer; C. W. Bliss, secretary, and C. P. Hollister, chief engineer. Messrs. Monypeny, Remington and Macgregor, with James Barber, William Grant Brown and R. T. McKee form the board of directors. The company was incorporated in June under the laws of the State of New Jersey with a capital of $500,000.

Enger Brings Out a $1,495 Six

CINCINNATI, O., Sept. 12—A new six-cylinder car has been brought out by the Enger Motor Car Co., Cincinnati, O., to sell for $1,495 with complete equipment, including electric lighting and starting; a single model is offered, six- or a seven-passenger touring car with a wheelbase of 124 inches and 34 by 4 tires.

The motor is block cast with cylinders 3 1-2 by 5, giving a S. A. E. rating of 29.4 horsepower; valves are enclosed. Ignition is by the Atwater Kent system with both automatic and manual spark control.

Electric lighting and starting are provided for by a separate generator and starting motor. The cooling water, pump circulated, passes through a square-tube honeycomb radiator. The carbureter is a Rayfield.

Power is transmitted through a multiple-disk clutch and three-speed gearset, forming with the motor a unit power plant, and propeller shaft to the floating rear axle. Wheels are of wood with Firestone demountable rims carrying 34 by 4 Firestone tires. Front springs are semi-elliptic and rear springs three-quarter elliptic.

The equipment consists of one-man top, quick adjustable curtains, windshield, electric horn, Stewart-Warner speedometer, extra rim and the usual tools, etc. A gasoline gauge is mounted on the dashboard, and, with the other instruments, is electrically illuminated. A dash adjustment for the carbureter is provided to make starting easy in cold weather.

Sphinx Co. Buys Hart Kraft Plant

YORK, PA., Sept. 12—The Sphinx Motor Car Co., York, Pa., has purchased the building formerly owned and occupied by the Hart Kraft Motor Car Co. and is manufacturing cars. Deliveries will be made October 1.

The dimensions of the property are 115 by 265 feet, and is located along the Pennsylvania and Western Maryland Railroads. The four-story building affords ample room for the production of 5,000 automobiles annually.

The style of the car will be a light touring car, fully equipped, including electric lighting and starting systems, at the selling price of $695.00.

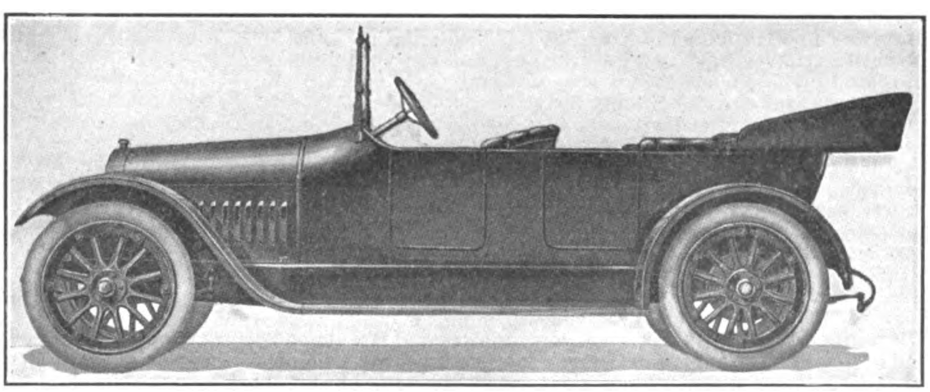
Herbert R. Averill and Ernest T. Gilliard will have the management of the factory. The following will be directors: Howard Rohrer, Jacob Rohrer, Lancaster, Pa.; Theo. C. Auman, Milton G. Hollis, Reading, Pa.; Dr. Posey, York, Pa.; Dr. Otto Schaefer and Thomas C. Goodwin, Baltimore, Md.

Studebaker Supplies Extra Coupe Bodies

DETROIT, MICH., Sept. 9—The Studebaker Corp. is furnishing Studebaker dealers and branches with coupé bodies which can be mounted on almost any chassis. As the Studebaker is not made with closed models, this will meet the demand of patrons who desire a closed car for the winter.

Stutz Light Four Runabout, $1,475

NEW YORK CITY, Sept. 16—The price of the new light four Stutz runabout is $1,475 with full equipment and not $1,450 as was stated in THE AUTOMOBILE for September 3 on page 468.



New seven-passenger Enger $1,495 light six

Buick Wins Wisconsin 500-Mile Reliability

MILWAUKEE, WIS., Sept. 11—Repeating his brilliant victory in the first Wisconsin reliability tour in 1910, Emil Hokanson, Madison, Wis., driving a Buick model C-37, captured two out of three trophies in the fourth annual Wisconsin reliability-economy tour, run over a course of 508.8 miles on September 7, 8 and 9, and might have taken the third cup but for the fact that six contestants drew lots for it. Franklin, Jeffery, Studebaker, Chevrolet and R. C. H. finished in the order named.

Buick Wins Economy

By averaging 24.8 miles per gallon of fuel, which figures 1,455 pounds per gallon, Hokanson's Buick won the economy test, and with a score of 2,995 out of a possible 3,000, was awarded also the $1,000 sweepstakes cup. A trophy, for best road score, was awarded to the Studebaker 4, the decision being made by drawing lots because all contestants finished with perfect road scores.

It was with a model 19 Buick that Hokanson won the cup in the initial tour for this trophy in July, 1910. In 1911 Hokanson finished second, and in 1912 he was tied with several other contestants for the major trophy and with the others received certificates instead of the cup. There was no tour in 1913.

Franklin Wins in Owners' Division

In the private owners' division, John D. Babcock, of Milwaukee, driving a 1911 Franklin 6, won over Henry O. Stenzel in a White 30, and becomes permanent possessor of the Emil Schandein trophy by virtue of having won the cup three times. Stenzel has been Babcock's competitor in this division since 1911 and tied the Franklin in 1912. This division was run under grade 3 rules of the A. A. A. and Babcock finished with a perfect score, while Stenzel suffered 31 points penalty for taking on water between controls and for work on a water connection.

The 1914 Wisconsin state tour was without doubt the most important run of the kind staged in America this year. The addition of an economy test made it the most important tour ever held in the country, for reliability has long since been proven, while economy has until now been a matter of guesswork.

Fuel Carefully Measured

For the purposes of the economy test, all gasoline tanks were emptied and filled with a supply of Bartles-Maguire 60-62 degree gasoline, carefully measured by pints, and all replenishment of gasoline supply during the run was as carefully measured and noted by the technical committee, under whose supervision all tanks were drained at the conclusion of the run and total consumption noted. All cars finished by 6 o'clock Wednesday, September 9, and were then returned to the official garage and kept locked up until Thursday morning, when brake, clutch and transmission tests were held. Immediately thereafter the technical committee tore down each car for final examination and was able to report to the contest board late Thursday that the Buick was entitled to the *Sentinel* and Wisconsin Motorist trophies and all cars were tied for the Milwaukee *Free Press* trophy.

All Were Penalized

As is shown in the report of the technical committee, not one car came through the exacting final examination without demerit. However, it can readily be seen that the majority of penalties thus assessed were of a minor character and proves the contention of many that the reliability of modern motor cars under the most exacting conditions cannot longer be questioned.

Each contestant started out with a credit of 3,000 points, divided into three sets of 1,000 points each, as follows: Road score, technical score, and economy score. The winning Buick lost only 5 points, which were assessed in the final examination, but for minor faults. The Franklin, Jeffery and Studebaker lost only 3 points each in the final inspection. The Chevrolet, which went into the technical committee's hands with a small fracture in the water jacket, was assessed 36 points for the fault, which was aggravated by the 500-mile run. The new R. C. H. suffered the heaviest technical penalties, being listed for a deduction of 159 points from its 3,000 for a net 2,790. The left rear axle shaft was broken, causing 100 points, and both sets of brakes failed to come to scratch, causing 50 more points to be added to the penalty.

Fuel economy was determined by dividing the total weight of the fuel consumed on the entire trip into the weight of the car, including passengers, driver, observers, tools, equipment, and everything complete as the car went over the roads in the tour.

Burman Sets World 15-Mile Record in 12:47

PEORIA, ILL., Sept. 12—Bob Burman today established a new world's record when he drove 15 miles on a circular dirt track in 12:47. The old record was 13:30, made by Disbrow at San Jose, Cal., April 14, 1912. Disbrow's mark of 13:03 for the same distance made at Hamline, Minn., Sept. 12, is also broken.

Burman's attempt today was in an official time trial.

64 Mile Average in Spokane Road Race

SPOKANE, WASH., Sept 10—Eight cars entered the 21-mile automobile race Labor Day on the course at Spokane, Wash., known as the Apple way.

The winner was a 50 horsepower Stutz car owned by Harlan Peyton and driven by Herb Alderson, who has captured many road and track races in the Northwest.

Ed McGoldrick's National was forced to retire by a broken drive shaft at the start of the race and Roy Nobel's Detroiter went into the ditch on the return lap.

Alderson drove the powerful car over the 21 miles of country road at an average of 64 miles an hour.

The little red Detroiter was racing neck and neck on the first mile of the return lap with Claude L. Laws's Hudson when he met with an accident which put him out of the race. The Hudson skidded and locked front axle hubs with the Detroiter. The latter was catapulted off the road by the shock, but landed right side up, both driver and mechanic escaping any serious injury.

Another car which had hard luck was Ray Paulsen's Lozier, which developed engine trouble on the first half of the lap.

A driving rain fell throughout the first part of the afternoon. In spite of weather conditions about 3,000 people saw the races. The course began 1 mile east of Spokane and ended at Liberty Lake Junction, a distance of 21 miles. The road was in perfect condition.

The winners of the race received a first prize of $210; $126, second; $84, third. Following is summary:

21 Miles Free For All	Out	Back	Round Trip
Stutz (Alderton)	10:14	9:27	19:41
Everett (Cunningham)	11:12	9:42	20:54
Hudson (Laws)	10:49	10:30	21:19
Chalmers (Schmidt)	11:45	9:51	21:36
E. M. F. (Morrill)	12:00	10:28	22:28
Lozier (Paulsen)	16:38	9:37	26:15

Faster time made on the return trip was due to the fact that the rain had stopped, permitting the drivers to follow the road more easily. Other events and results of smaller races on the Apple way, were, as follows:

100-Yard dash, three gear shifts—Won by Joe Stenstrum, Chalmers Six; time, 12 4-5 seconds. Dr. Hahn's Lewis six, second; J. A. Raymer's Hudson six, third.

100-Yard race, low speed on high gear—Won by A. D. Jones' National; time, 1 minute and 14 seconds; Verne Dempsey's Chalmers, second; H. A. Fletcher's Lozier, third.

Tire change followed by 100 yard dash—Won by Roy Nobel in Detroiter; time, 2 minutes and 8 seconds; Cunningham's Everett, second.

100-Yard race from start with dead engine—Won by D. R. Riegel's Detroiter; time, 14 seconds; Fletcher's Chevrolet, second; Smith's Hupmobile, third.

In the tire changing event the Detroiter's driver and mechanic stole a march on their competitors by dispensing with the use of a jack, raising their light car by hand to put the tire in place.

During the big race the course was patrolled by national guardsmen stationed at every crossroad to warn vehicles. Some criticism was elicited, however, by the failure of officials to keep the crowd from the track near the start of the race.

30 by 3-Inch Tire, $6.75

NEW YORK CITY, Sept. 16—In an advertisement in THE AUTOMOBILE in the issues of August 27 and Sept. 3, it was stated that the price of the 30 by 3-inch tire advertised by the Fire Sales Co., 1334 Arch street, Philadelphia, Pa., was $5.75 when the price is $6.75.

Eight Cylinder Motors for 1915

(*Continued from page* 428)

being placed directly above the camshaft. The generator runs at camshaft speed. At the rear end of the generator is the train of gears which mesh with the teeth in the flywheel rim for cranking purposes. These gears are not in mesh unless the starter pedal is depressed, and the reduction between electric motor speed and engine speed is 25 to 1. The Delco unit temporarily becomes an electric motor in the usual way of cranking.

Wheelbase 2 Inches Longer

The Cadillac changes this year are not all in the motor, for the chassis is altered considerably also. The wheelbase has been lengthened from 120 to 122 inches, while left drive and center control replace right drive and control. The hinged steering wheel, which was an innovation last season, has been retained.

In the transmission system, a big alteration appears in the incorporation of the gearset in unit with the motor instead of locating it amidships as heretofore. The same type and design of three speed sliding gearset is used, however. The cone clutch has also given way to a nicely designed disk clutch of the dry plate type. This has fifteen carbon steel plates 7 3-4 inches in diameter, the driving plates, eight in number, being faced with wire mesh asbestos. This construction has resulted in an exceedingly soft-acting clutch.

The drive shaft back to the axle continues to be of the uninclosed type, fitted with two universals and being paralleled by a triangular torque arm.

A floating type rear axle which is similar in general construction to that formerly used is employed. This axle is, however, of the latest form in that worm bevel gears replace straight bevels for the ring gear and driving pinion.

Spiral Bevel Rear Axle

The spiral bevel gearing which appeared last year provides a rolling contact along the teeth and this is conducive to smooth running and quietness. It is looked upon as the last word in rear axle drive refinement, and in order to generate these complicated gears, the Cadillac company has installed an elaborate equipment of machines which give a movement of the cutter with respect to that of the gear blank itself in exceedingly complicated fashion. Very close limits of accuracy are obviously necessary in generating such teeth.

In other respects the chassis is about as it was. The frame is of bottle neck form, 33 inches wide in the rear and 30 at front. The characteristic Cadillac platform rear spring suspension is retained and its easy riding qualities are commendable. The gasoline tank is at the rear with pressure feed to the carbureter. Tires are 36 by 4 1-2 inches on demountable rims and wood wheels.

It is a notable fact that the new Cadillac is much lighter than its predecessor.

Bodies for 1915

Bodies have come in for little change, being of the smooth sided type with present-day lines gracefully worked out. The usual array of closed types is offered, while in addition to roadster and five- and seven-passenger touring types, a four-passenger salon, of open car design, is an attractive member of the family. This car provides a passageway to the rear seat and between the individual front seats. There is only one front door to it.

As regards prices, there has been no change made. Nineteen seventy-five is asked for any one of the open models, while the usual increases are required for the closed line. Equipment is complete in every detail.

Headlight Committee Appointed by Indiana S. A. E.

INDIANAPOLIS, IND., Sept. 15—*Special Telegram*—At the monthly meeting of the Indiana section of the Society of Automobile Engineers, held in the rooms of the Hoosier Motor Club, of this city, a committee composed of Howard C. Marmon, Nordyke and Marmon Co., George A. Weidely, Premier Co., and J. W. Esterline, Esterline Co., was appointed to take up with a committee from the Hoosier Motor Club, the matter of non-blinding headlights. These committees will act with the city and state officials.

NEW YORK CITY, Sept. 15—At a meeting of the Contest Boara of the American Automobile Assn. held today, Wm. Schimpf, who held the position of chairman of the board for 2 years, 1912-1913, was presented with a gold watch by the contest board in recognition of his services.

At today's meeting Hughie Hughes and Ray F. Brock were suspended for 2 years for failure to live up to contracts with promoters requiring their appearance at races.

Two records were officially allowed, one 100-mile for dirt tracks made by Ralph De Palma, in a Mercedes, at the Labor Day, Brighton Beach meet; time 1:40:15. The other was a 25-mile record established by Percy Barnes in a Romano car at Portland, Ore., July 12; time 22:07 1-5.

Accessories for the Automobilist

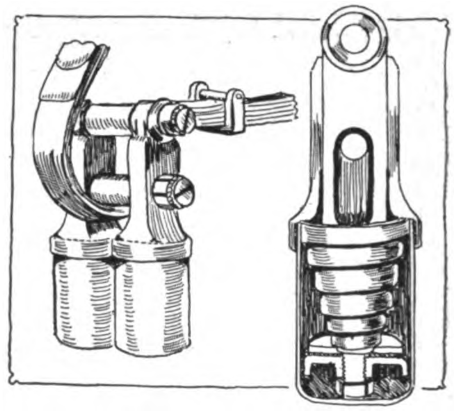

Fig. 1—Geschwa shock absorber. The air piston takes the rebound

GERMAN - AMERICAN Aluminum Solder—To dispense with the present oxy-acetylene method of repairing fractures in aluminum parts is the object of the German-American Aluminum Co. which has just established a sales office at 25 West Forty-second street, New York City.

The new solder is the invention of Karl R. Peters, a metallurgist of Berlin, Germany, and at the present time it is being manufactured in this city as well as in that country. The inventor claims that no breaks are too complicated to be repaired by the new method and that the work can be done at a saving of at least one-third the cost of the welding job. The strength of the solder, according to Mr. Peters, is about double that of aluminum as regards its resistance to tensile strains and even greater as regards its resistance to bending.

Outside of the greatly reduced cost of making the repair, it is claimed that the work attached to the job is no more than in ordinary soldering. Instead of having to purchase an expensive welding outfit, in the nature of oxygen tanks, acetylene and welding jets, the ordinary gasoline torch can be used. Another advantage claimed by the German-American company for its product is that the work requires no machining after the soldering is run in place.

In performing the work on an aluminum casting that has been broken into a number of pieces, the various parts are matched as closely as possible and screwed down on a jig. The fractures are then chiselled in the form of a V-shaped slot in the same manner as for a welding job. The solder, which melts at a temperature of 400 degrees Fahrenheit, is then run into the slot and finds its way down into crevises between the two pieces of metal. Upon solidifying the joint is made.

Mr. Peters states that he has had 8 years' successful experience with his solder both in this country and abroad. It is a secret composition, containing eight ingredients, five of which are metals and the other three salts of metals. The German-American company will either do the repair work itself at its factory at Port Jefferson, Long Island, or will sell the solder, together with territorial rights and instructions for its use in garages and repair shops. A guarantee is made that regardless of the work to be performed that the aluminum will break before the soldered joint under any ordinary strain.

Geschwa Shock Absorber—A combination spring and pneumatic shock absorber is shown in Fig. 1. The spring is a spiral type and it is situated in the top of the casing, while at the bottom is the piston and compressed air chamber.

The instant a primary jolt or shock is transmitted to the body springs of the car, the flat spiral coil spring of the absorber compresses in proportion to the extent of the jolt or shock and draws up the hanger and piston of the absorber from the bottom of the cylinder. The cylinder then takes in air on the principle of an air pump. On the rebound, which is the downward stroke of the hanger and piston, the air gradually is expelled through the relief hole at the bottom of the cylinder. Each rear set has four relief holes which control and check the excessive recoil and absolutely eliminate the series of oscillations occurring directly after spring expansion, it is claimed.

The shock absorbers are made in three sizes costing $45, $50 and $60 per pair. They are sold by the Marolin Co., 30 Church street, New York City.

Bench Machinist—A combination lathe, drill press and milling machine is shown in its various roles in Fig. 2. It is made by the Hunt Engineering and Sales Agency, 320 Lissner Building, Los Angeles. This machine is adapted to all kinds of small machine work—boring, turning, threading, milling, drilling and tapping, at any angle; die-sinking and routing. The universal feature of this machine is obtained by means of swinging the spindle—in the vertical position it rotates the drill; in the horizontal position it drives the face plate or lathe chuck or the milling cutter.

The spindle is driven through a three-step cone pulley and telescopic shaft, with two universals. In the head are two bronze mitre gears, and the spindle passes through one gear with a feather key. The power-feed screw is actuated by a train of spur change gears on a radial arm which engages either with the end of the spindle when in a horizontal position or with a special worm gear attachment driven from the cone pulley which is furnished with the machine when desired.

As a drill, the work is clamped to the table and by the use of cross and longitudinal feeds is adjusted to any desired position. For drilling and tapping at any angle, the spindle may be adjusted and the work brought to the tool. The capacity of the drill is ½ inch.

As a lathe, the spindle is horizontal. The face plate is 5 inches in diameter, but much larger work than this may be swung. As the head is adjustable to any angle, any taper may be cut. If a tail stock is required a dead center may be attached to the extension arm, as when used as a milling machine.

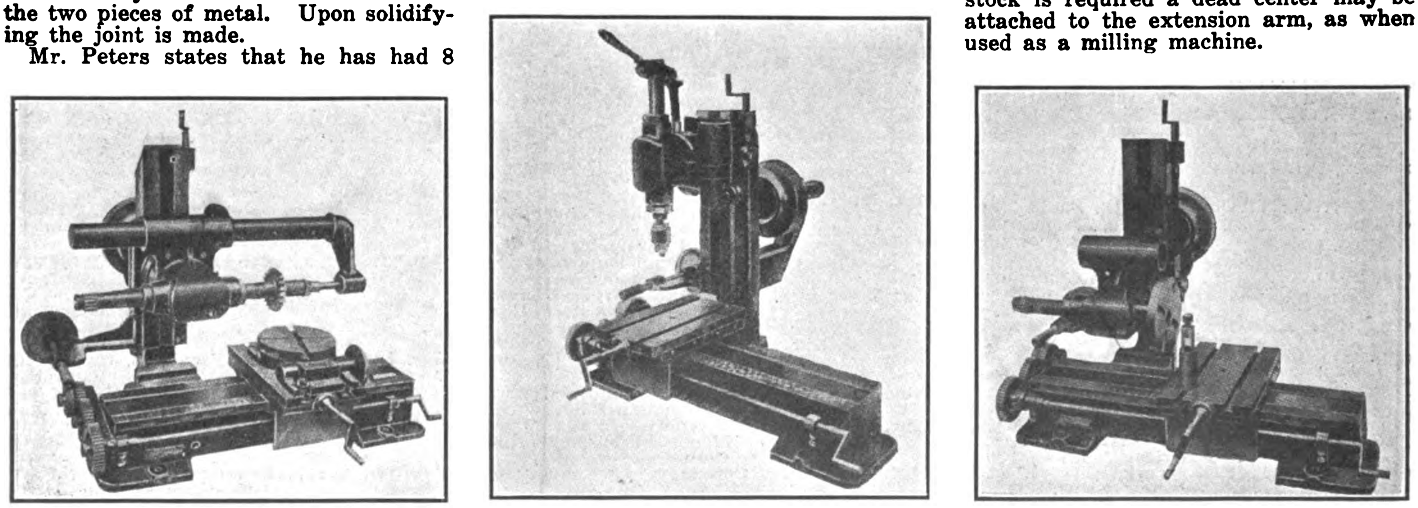

Fig. 2—Bench machinist which combines many machine tools in one. At the left is the device set up as a milling machine; in the center it is a drill press and at the right it takes the form of a lathe. The universal feature is obtained by means of swinging the spindle. It is made by the Hunt Engineering and Sales Agency, Los Angeles

The AUTOMOBILE

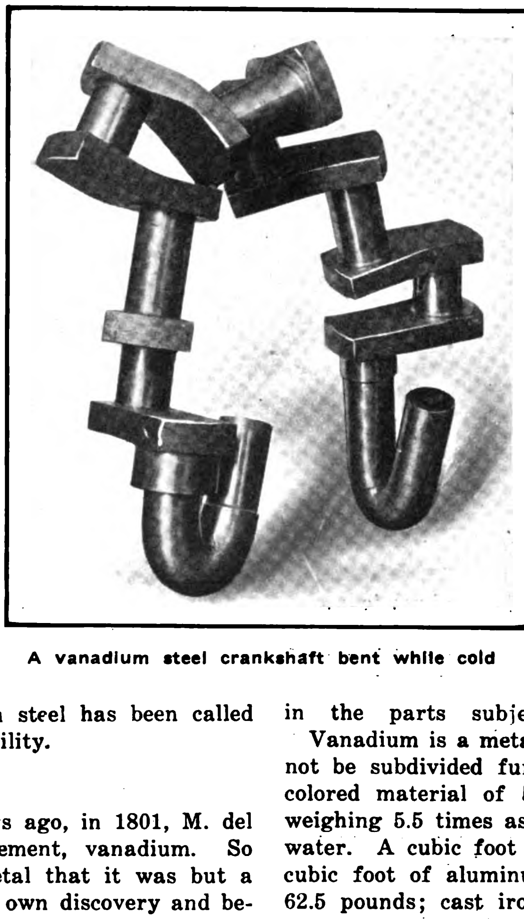
Vanadium—A Vitalizer of Steel

Mined in the Clouds, the Element Finds Its Way Into Automobile Axles, Crankshafts and Springs

By J. Edward Schipper

A VANADIUM steel axle can be tied in a knot without breaking. Any mechanical handbook will tell you that the effect of vanadium on steel is to increase its tensile strength and its elastic limit. Furthermore it will tell you that the use of vanadium in proportions of from .16 to .25 per cent. gives the metal the valuable property of resisting, to an unusual degree, repeated stresses.

No piece of machinery has so called upon the efforts of science in the production of metals as the automobile. In the search for the dual qualities of lightness and strength the value of every known alloy has been tried to the utmost, and nowhere has success been met with in a more gratifying manner than in the use of the alloy, vanadium. For springs, axles and gears subjected to hard service and for parts which must withstand the stresses of vibration and the tendency of crystallization, vanadium steel has been called upon to assume the post of responsibility.



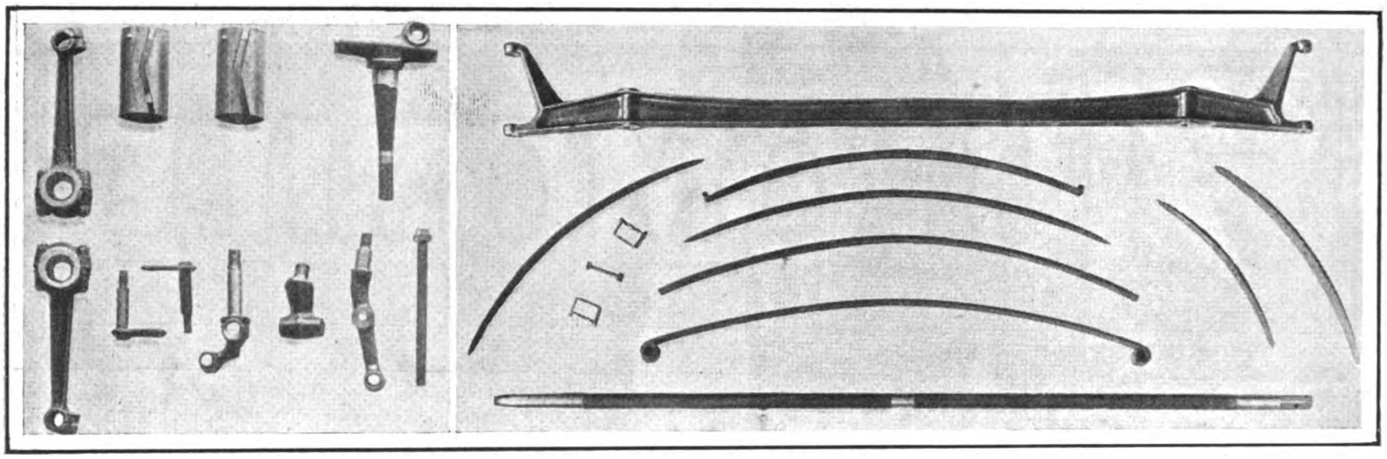
A vanadium steel crankshaft bent while cold

A Hundred Years Old

A little more than a hundred years ago, in 1801, M. del Rio first mentioned the metallic element, vanadium. So elusive was the newly discovered metal that it was but a short time later when he doubted his own discovery and believed that what he had thought to be vanadium was nothing but an impure chromium. In 1830 N. G. Sefström discovered traces of the vanadium content in the slags of the Taberg iron ores. Finally, Sir H. Roscoe managed to segregate the element from its impurities and to determine its correct atomic weight and to place it in its correct group in the series of elements. He incidentally showed that what previous investigators had thought to be vanadium, was merely a nitride or oxide of the element.

It was not until very recent times that the use of vanadium in combination with iron and steel began to be a commercial enterprise of success. In the accompanying chart on page 566 the popularity of vanadium steel in recent years is clearly shown. More than twenty-three times the quantity of vanadium is used for this purpose than in 1908. It cannot be gainsaid that the automobile industry uses a large percentage of the total output. The Ford car, for instance, uses vanadium steel throughout the motor and entire chassis. And this is only one of the representative concerns which have found this alloy to be of use in the parts subjected to the severest strain.

Vanadium is a metallic chemical element. That is, it cannot be subdivided further into components. It is a light-colored material of 5.5 specific gravity, in other words, weighing 5.5 times as much as an equal volume of distilled water. A cubic foot of vanadium weighs 343.2 pounds. A cubic foot of aluminum weighs but 159.7 pounds; water, 62.5 pounds; cast iron, 450 pounds; lead, 709 pounds and iridium, 1,400 pounds. From this it is shown that vanadium is a comparatively light metal and hence, would tend to lighten rather than to make heavier the steel with which it is combined. The percentage of vanadium added to the ladle averages about .15 per cent. and hence, the weight is not



A few of the vanadium steel parts used in the Ford car. Many more parts of this alloy steel are employed

Llamas transporting the ore from the Peruvian mines

greatly affected either way in making up the alloy steel.

While vanadium ores are found in the United States, the largest company operating in this country is using the ore from the mines of Peru. In America the principal deposits are found in Colorado and Utah and recently a deposit of vanadium ore has been discovered in California. The ores of America are known as vanadite, mottramite, descloizite and roscoelite. It is also found as a constituent of various clays, iron ores and pitchblendes. The ore which is found in Peru and which has a far larger percentage of vanadium than any that is found in the United States is known as patronite. The color of the ore is brighter than that of the ore of Colorado and Utah and carries as much as 50 per cent. vanadium oxide. The patronite, the main source of vanadium mineral, is greenish black and has a hardness of 2.5 and a specific gravity of 2.71. It contains from 19 to 24 per cent. of vanadium oxide, while the miners in the Colorado and Utah mines have a hard time in securing ore valuable enough to ship for refining purposes and yet anything which contains more than 3 per cent. of vanadium is worth shipping.

Some of the physical qualities of vanadium which are of note are that it is not volatilized, even when heated to redness in a current of hydrogen and it is insoluble in hydrochloric acid. It precipitates platinum, gold and silver from their salts when in solution.

Ores in the Mountains

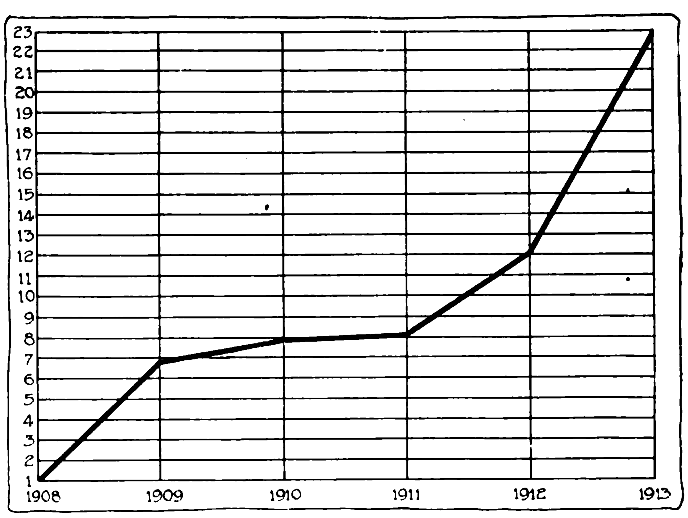
In the United States the ores are found in the higher plateaus of southwestern Colorado and southeastern Utah in the form of soft sandstone. The same ore from which vanadium is extracted is also the source of supply of a large percentage of the world's supply of the rare metal, radium. In fact, much of the ore has been mined for the purpose of extracting this rare substance and only that having the largest percentage of vanadium has been used for the purpose of securing the latter metal. The ore known as roscoelite comes from Placerville, Col., and on the north side of the San Miguel river, between Sawpit and Placerville.

The ore is generally found lying on one or both sides of a parting in the sandstone and in most places the vein is less than 1 inch thick, consisting of roscoelite and a little quantity of quartz which often carries as much as 8 per cent. vanadium. The ore has to be then very carefully selected so that it gives at least 3 per cent. of vanadium. By far the largest part of the vanadium-bearing rock in this country carries less than 1 per cent. vanadium. The ore is often found as vanadinite in fine crystals in combination with other minerals such as lead and copper.

Rich Ores in Peru

The American Vanadium Co. in 1905 located the rich deposits of vanadium sulphite ore in the Peruvian Andes. These deposits are located at almost the very topmost point of the mountains, being 16,200 feet above sea-level, and establishing the site of what is probably the highest factory in the world. The buildings of the main plant in Pittsburgh are illustrated. There is an ore-storage building, the interior of which is also shown and the furnace and reduction plants are also completely outfitted at the top of the mountain. The ore is named patronite afer the name of the original discoverer of the Peruvian deposits, M. Antenor Riza Patron.

Four reverberatory roasting furnaces are used for reducing the ore at the mines, and in this form it is transported on the backs of llamas to the railway which is 28 miles distant. The nearest point to the mine is Fernandini



Curve showing increase of vanadium steel using 1908 as a unit station on the Central Railway of Peru. From this point it is taken to the coast. It is stated that each llama will carry a 110-pound sack of the ore and if as much as a pound or two of extra weight is added to the burden the animal will refuse to move. In building this plant on the top of the mountain, the American Vanadium Co., which owns the mines, states that every brick had to be carried to the factory site on the backs of the patient beasts of burden before the factory could be built.

Coming down to the use of vanadium in the manufacture of modern machinery, it is found that it is in parts subject to the racking and pounding of travel, that it finds its principal use. For this reason it is not surprising to find that it plays a prominent part in the manufacture of locomotives and automobiles. In the framework of locomotives which are subject to the stresses of the huge driving forces, vanadium steel has proven a success. On the Chicago, Rock Island & Pacific Railway, there are thirty locomotives, each weighing 281,500 pounds, all of which are equipped with vanadium steel frames. On other locomotives the axles, crank pins, and side rods are of this metal. On the Baltimore & Ohio road a 462,000-pound locomotive is using heat-treated vanadium steel tires. The elastic limit of heat-treated carbon steel generally averages from 50,000 to 55,000 pounds per square inch. That of chrome-vanadium steel forgings will average from 80,000 to 90,000 pounds per square inch.

By the adoption of heat-treated chrome-vanadium steel frames for their London type busses, the Fifth Avenue Coach Co., of New York City, states that it has overcome considerable trouble that it was experiencing with frame fractures. Previous to using the vanadium steel, this concern used a high-grade carbon steel, heat-treated, but with this, frame trouble was experienced from breaking and also from the fact that the side members would take a permanent set.

Used in Truck Frames

The vanadium steel frames have been in use in this service for over a year now and the company reports that they have so far shown no signs of bending or breaking. The main frame, complete with the engine cradle is made of chrome-vanadium steel. The construction consists of riveting two vanadium steel plates 15-64 inch in thickness, with an ash filler 1 3-16 inch thick between. The vanadium steel is heat-treated and has an elastic limit of 95,000 pounds per square inch, a tensile strength of 120,000 pounds per square inch and an elongation of 18 per cent. in 2 inches. In weight, the vanadium steel frames are slightly lighter than the carbon steel frames previously used. The total weight of the old frames with engine cradle and feltings, was 865 pounds, while the weight of the new frames is 850 pounds. Thus, by the use of vanadium steel a much stronger frame has been secured, not only without any increase but with a slight decrease in weight.

The American Vanadium Co., which has its general offices in Pittsburgh, has a reduction factory at Bridgeville, Pa., about 12 miles from Pittsburgh. After being transported on the backs of several thousand llamas on the trails of Peru, then being transported by freight car to the coast and by steamer to America, the reduction process is given in the Bridgeville factory. This plant is designed and equipped to produce 30,000 pounds of ferro-vanadium a day, and it is in this form that it is added to the steel.

In the form of ferro-vanadium, or vanadium mixed with iron, the alloy is sold to the steel manufacturer and by him it is put into the steel to meet the requirements of the manufacturer. For automobile manufacturers the Society of Automobile Engineers has specified chrome-vanadium steels

Pros and Cons of the Eight Motor

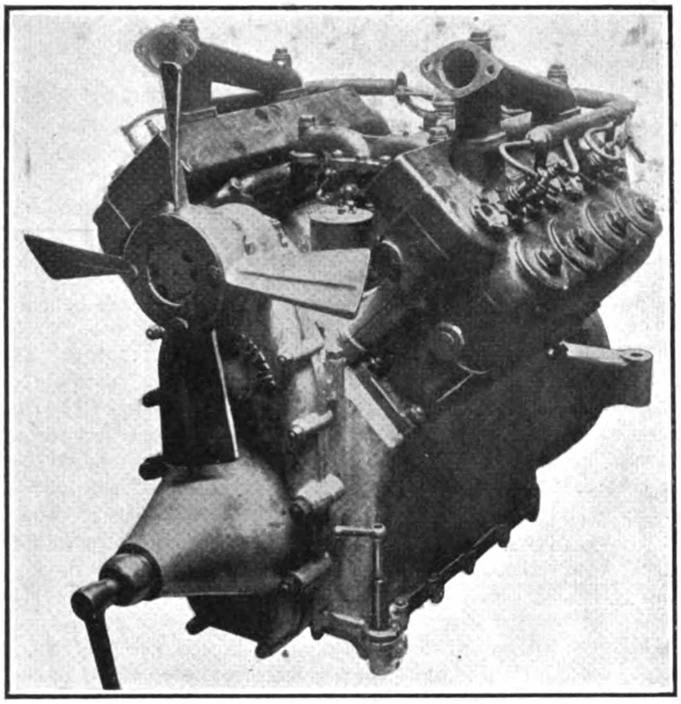

Fig. 1—Eight-cylinder De Dion motor of 30-horsepower. This is a 1911 model but is the same as the present design except in minor details

Lighter and More Economical Than Six-cylinder — Ultimate Type Except for the Small Four

By OWEN THOMAS

EDITOR'S NOTE—This article by Owen Thomas, of the engineering firm of Thomas & Thomas, Kenilworth, England and New York City, is based on an analysis of the De Dion eight-cylinder motor design extending over a period of more than 3 years. Mr. Thomas tries to show in this first article of a series that the four-cylinder motor design inevitably leads to the small-bore high-speed, high-efficiency four-cylinder car of Europe and that these principles can only be applied to larger motors by the use of eight cylinders. This is the most complete article that has been printed in an American journal on the subject of high-speed, high-efficiency motors by an engineer who has had actual experience with these motors in Europe.

FOUR-CYLINDER motors of maximum efficiency and horsepower for a given size and weight can not be built with a bore much exceeding 3 inches, if extreme durability is desired. Since the bore is thus limited, an increase in power calls for the addition of cylinders. The six-cylinder motor weighs more per horsepower and entails a longer and heavier car. The eight fulfills the demand for a motor of more power, because it weighs, if anything less than the four and is as efficient as a four of the same power.

Before attempting to prove the claims of the eight, as to flexibility, thermal efficiency, power output per pound, and durability, a successful motor, the De Dion, that has been tried out for several years will be described in detail, and proof of the excellent wearing qualities of this type of motor will be given. With the details of the eight-cylinder construction thus well in mind, this form of motor will be analyzed and reasons for believing that this is the ultimate type of motor for all, except low-powered cars, will be set down in detail.

It is interesting to note, at this point, that in speaking of the début of the eight-cylinder V-type motor in America few realize that there are running in New York today over 100 De Dion Bouton eight-cylinder cars varying in horsepower from 20 to 50. The first of these cars of 50 horsepower was sold in May, 1909, but it was not until 1911 that the 30-horsepower model made its appearance. The motor of this car had eight cylinders, of 70 millimeters, or approximately 2 3-4 inches bore by 130 millimeters, or approximately 5 1-8 inches stroke.

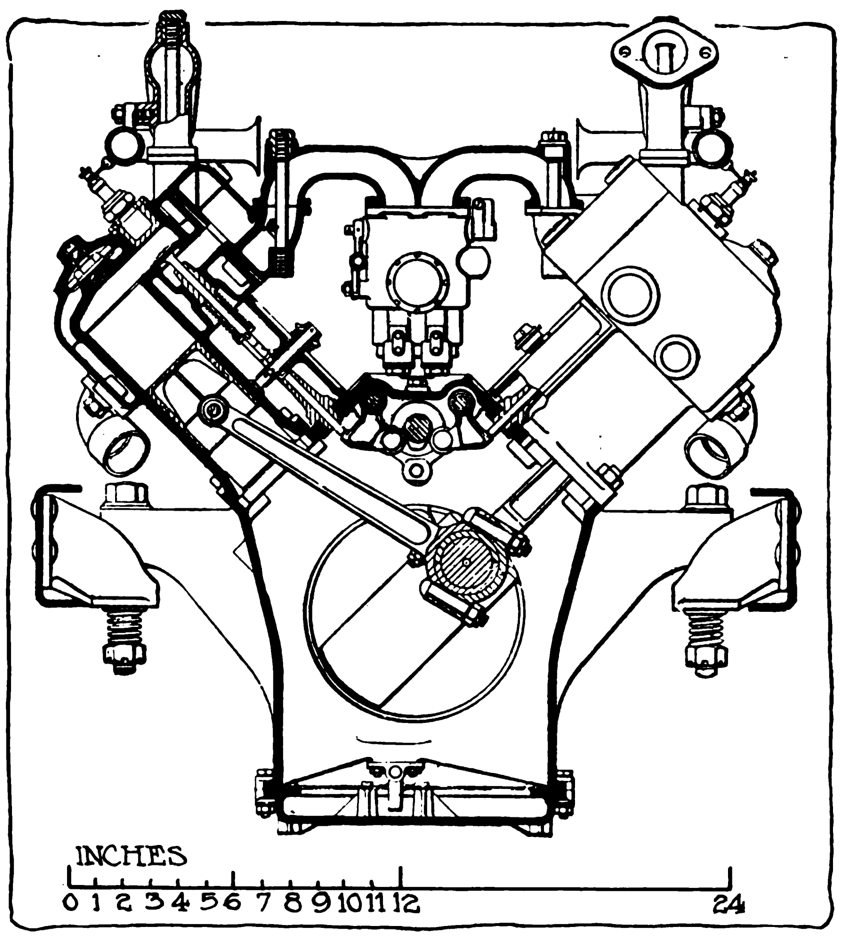

Fig. 2—Part section through motor showing mounting of double carbureter, arrangement of valve mechanism and the connecting-rod construction. Note the springs used in anchoring the motor to the frame

In 1913 this 30-horsepower model was superseded by another of 75 millimeters, or approximately 2 15-16 inches, bore, with the same stroke as before, and a new 24-horsepower model having a bore of 66 millimeters or 2 5-8 inches bore by 130 millimeters or 5 1-8 inches stroke, was added. All of the cars sold, except two, are in the hands of the original owners, these two having been replaced by larger cars of the same make. Last week an effort was made to procure for a Detroit firm one of these worked-in cars but there was not one available.

The beginning of this month saw the taking down and reassembling of the first of the 30-horsepower cars. At the time of this examination the accompanying photographs, Figs. 1 and 4 to 11, inclusive, were made.

First Motor Overhauled

While this motor is not the latest model, it is worthy of close study because it is the first eight-cylinder motor that has been dis-assembled in this country and therefore the only one whose condition is exactly known. At the time it was overhauled it had been driven 32,000 miles with a limousine body. It was found that all the surfaces were in good condition but that the cam and valve mechanism had showed slight wear. This is proof that this type of motor is most durable and improvements that have been made since in this design indicate that this record should be exceeded.

The general form of this motor is shown in Figs. 1, 2 and 3. It is an L-head design with the cylinders placed at 90 degrees and cast in blocks of four. The spark plugs are located over the intake valves and there are removable caps that give access to the cylinder interiors.

The cooling system is thermo-syphon; the water pipes above each bloc taper from 1 3-8 inches inside diameter to 1 3-4 inches inside diameter.

The fan in this model has four blades and runs 1 1-3 times engine speed, while in the later motors it runs with the magneto drive at engine speed and has eight blades.

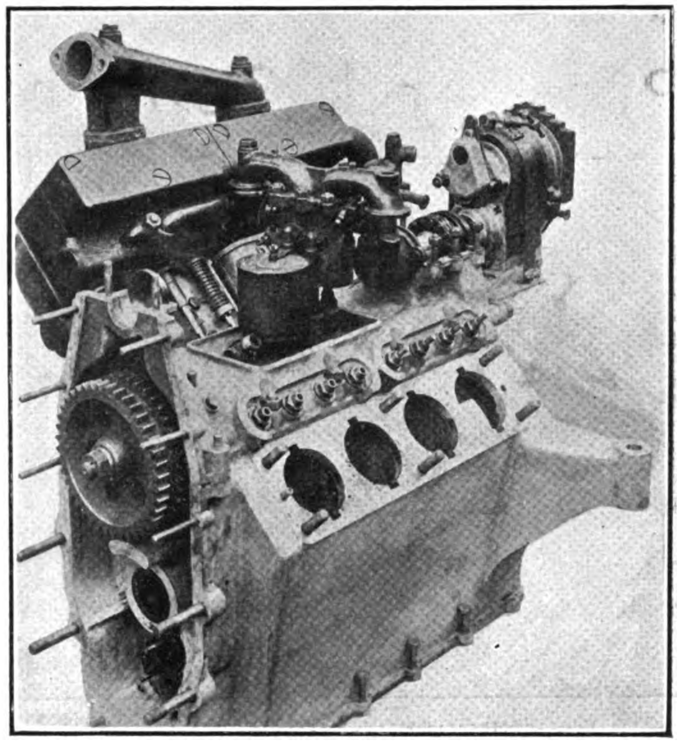

Fig. 4—Motor with left cylinder block and timing gear cover removed

The magneto is a Bosch model H.L. 8. The armature revolves at engine speed, the half-time shaft carries at one end an eight point, high-tension distributer and at the other, an eight point cam, operating a single contact breaker which is carried in a fixed case, giving no variation in the timing of the spark.

The carbureter is carried high between the Vs and connects to the cylinder blocks by means of very short intake pipes. Two separate Zenith carbureters with a single float chamber are employed, balanced throttles being used. This undoubtedly sacrifices the flexibility of the motor to the limitations of the fixed Venturi tube carbureter. So perfect is the balance of this type of motor and so small are the losses that it is more flexible than the carbureter and the difficulty is to find a standard carbureter that will satisfactorily meet the demands of the motor. The intake piping is 7-8 inch.

The depression for the carbureter, Fig. 3, is provided with a copper tube drain cast in, to carry off any leakage of gasoline to the opposite side to that shown.

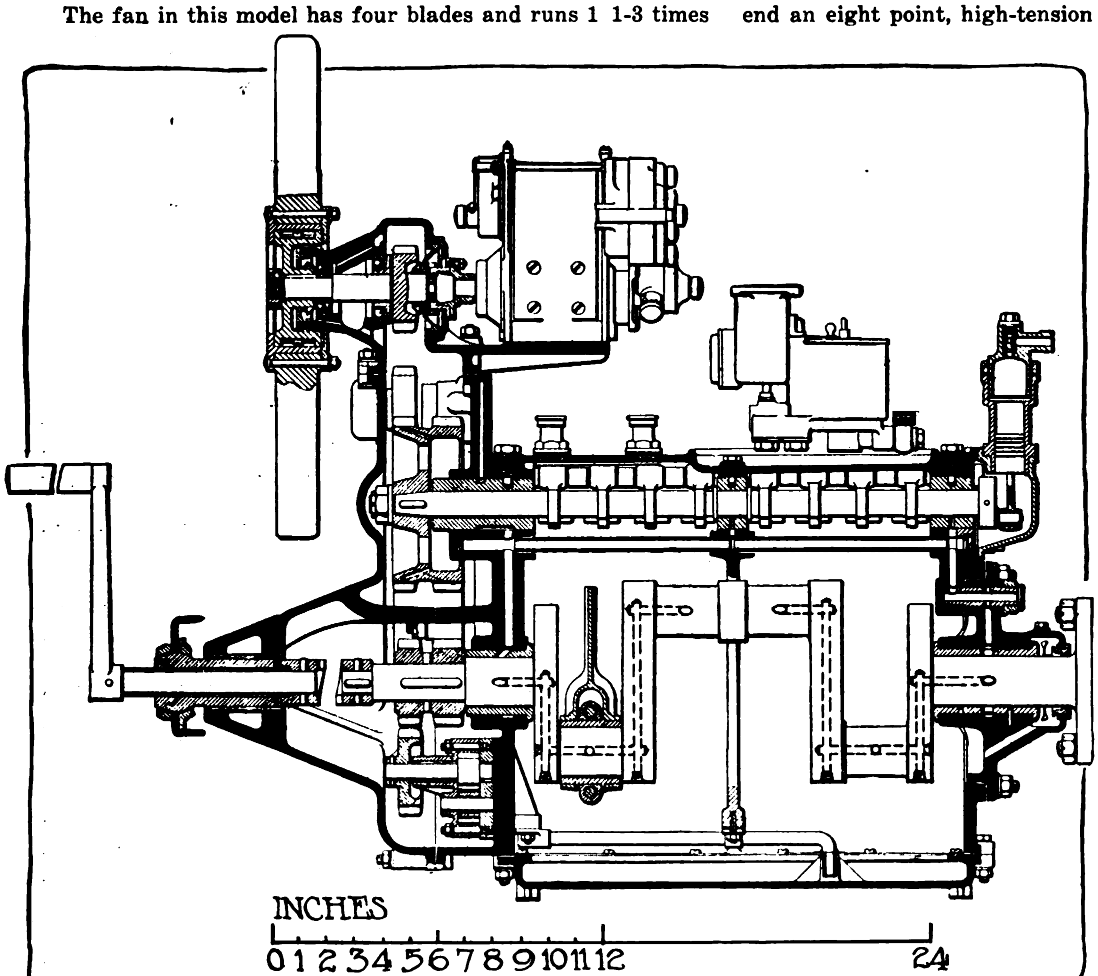

Fig. 3—Longitudinal section through motor with cylinders removed illustrating motor details

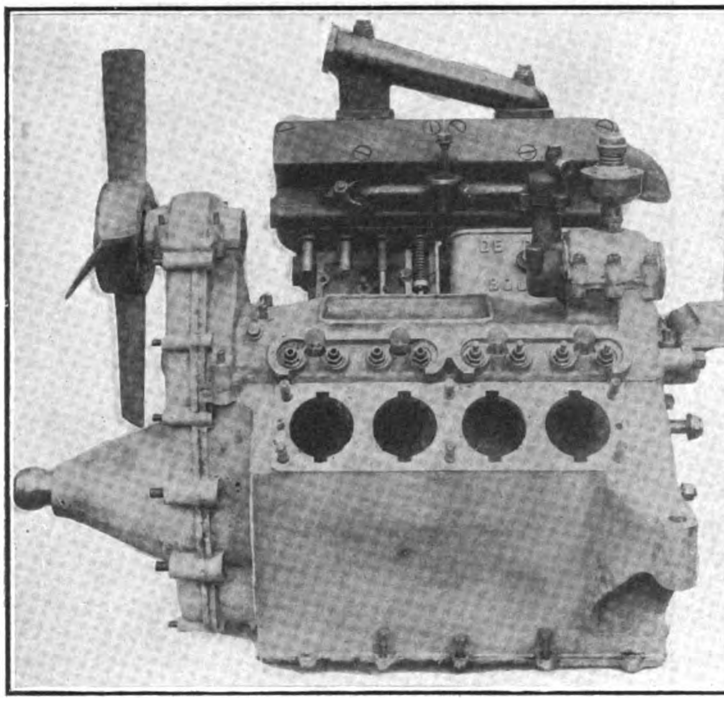

Fig. 5—Left—Another view of the motor with the left cylinder block removed

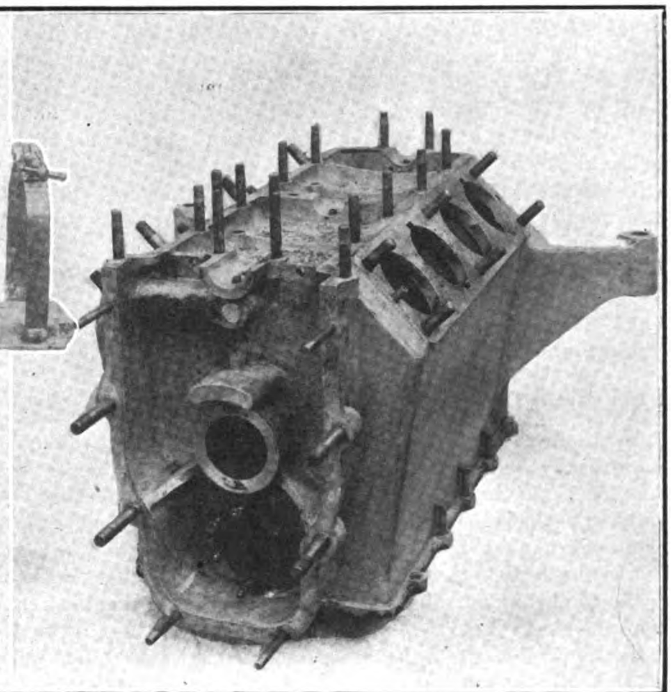

Fig. 6—Right—Crankcase casting illustrating the studs for holding the parts

The exhaust passages are smaller than usual, 1 1-8-inch pipes from each bloc join together into a common 1 3-8-inch diameter exhaust pipe and a single muffler. Larger pipes would undoubtedly increase the output at high speeds.

Force Feed Oiling

The lubrication system is by force-feed, Fig. 3. The crankshaft is drilled to the pins of cylinders 1 and 2 from the front main bearing, and to the pins of cylinders 3 and 4 from the rear main bearing, the drilled oil holes being 1-4-inch diameter. All the oil holes in the case, including the copper tube cast in, are 1-2-inch diameter inside. The rod bearings are held and pinned in the forked rod. An oil hole through the bronze bearing lubricates the outer surface of the bearing on which the center rod runs between the forked ends of the other rod. The oil thrown from the main and rod bearings lubricates the pistons and other parts. All the camshaft bearings are pressure lubricated. The oil pump running at engine speed has gears 1 3-16-inch pitch diameter, with 12 teeth and 13-16-inch gear face. One gear is integral with the steel shaft, the other is bronze, running on a hardened steel pin which is supported at both ends.

The pump supplies about 20 pounds pressure per square inch at 500 revolutions per minute and about 40 pounds at 1,200 revolutions per minute, the pressure being regulated automatically by the action of a spring valve, shown horizontally, Fig. 6, just under the camshaft bearing. The surplus oil escapes through the two small holes shown in the plunger valve casing and is used for the lubrication of the chain drive. A spring indicator warns of insufficient pressure or oil.

Fig. 10 shows the oil base and screen, the oil pump and suction pipe and the valve-cover parts. The large hole shown in the screen is for the insertion of the suction pipe, the small standpipe at the left is evidently a vent to prevent heavy oil trapping air under the screen.

Fig. 4 shows the cam case cover, one cylinder block and the carbureter, the magneto and air pump in place. Fig. 5 shows the same with the exception of the carbureter and magneto, but with the front chain case and fan cover added.

The bottom flange has 12 bolts and 2 studs, all 8 millimeters diameter.

The upper cam case is held down by fourteen 10 millimeter studs. Fig. 6 shows the oil pockets on top of case into which the cams dip. The hub of the front main bearing is 1-2-inch thick, carrying a 5-16 solid bronze bushing.

The rear flange, to carry the split rear bearing flange, is 13-16-inch thick with 5-8-inch face, Fig. 9. The center web has a hole 7 1-2 inches diameter and is full 3-8 inch thick. The center pad on this web is a support for the oil pump suction pipe. The other two webs die into the case at the side and are tapered down to 1-4-inch at the edges.

Order of Firing

The cam action layout is shown in Fig. 12. The order of firing is:

Right—	1		3		4		2	
Left—		4		2		1		3

Reading zigzag: 1,4; 3,2; 4,1; 2,3, first on the right side and then on the left side of the motor. It will be seen that each pair adds to 5 and that unlike the four and six-cylinder motor, they balance equally to the front and rear.

In other words, if any diagonal pair of explosions adding up to 5 is taken, it will be noted that the diagonal drawn between these two cylinders will pass through a point exactly in the center of the motor.

While there are eight possible firing orders there are only two that can be utilized if full advantage of the eight-cylinder principle is taken.

There are eight cams on the camshaft, four for the intake and four for the exhaust. Each pair of four are equally spaced, being set at 90 degrees.

Since the cylinders are set at 90 degrees it is natural to assume that the valve mechanism, Fig. 12, would be laid out so that the cam opening the intake valve on the right cylinder, number 1, for instance, would open 90 degrees after that on left cylinder, number 4. But this is not the case because the camshaft is rotating at half the crankshaft speed —a 90-degree movement of the crankshaft results in only 45 degrees on the camshaft. While the crankshaft is moving 90 degrees the camshaft goes only 45, with the result that in order to open the second valve 90 degrees of crank movement after the first, the spread between the cams must be 90 plus 45 or 135 degrees.

Fig. 12 shows this plainly, the 135 degrees representing the interval between the firing of cylinders left 1 and right 1. On the later type engines the rocker parts are all assembled on the rods and put into the case itself instead of being assembled in the separate cover as shown in the photographs of the 1911 70-millimeter motor.

The rods in various combinations on the crankshaft are illustrated in Fig. 8. The complete twin rods are shown on the rear pin. The complete bronze bearing, clamped and doweled in the forked rod, is shown on pin 3. Small flanges on the bearing, about 1-16 inch wide and high, locate the forked rod on the bearing by fitting between the two sides of the fork. They also serve to take the side bearing of the single center rod and prevent it from rubbing the inside of the forked rod. The outside of the bearing is 58 millimeters in diameter, where the forked rod clamps and the center rod bears. The fit of the center rod is 22 millimeters wide and each side of the forked rod is 16 millimeters wide.

Motor Part Dimensions

All of the shaft bearings are 44 millimeters diameter; the front main bearing and all of the rod bearings are 58 millimeters long; the rear main bearing is 110 millimeters long. The shaft is 54 millimeters diameter between the rod bearings of cylinders 2 and 3.

The crankshaft cheeks are all 64 millimeters wide, the end cheeks are 64 millimeters by 23 millimeters in section and the cross cheeks are 64 millimeters by 34 millimeters in section. The crankshaft is finished all over, the pins and bearings being ground. The side bearing surfaces of the rods present a face 3-16 inch wide. The drilling of the crankshaft is described under lubrication.

The pistons are 84 millimeters long by 70 millimeters diameter. They have three wide rings, all above the piston pin bearing. The pistons are forged and turned out very thin and light. The pins are 12 millimeters diameter; they are held by two taper pointed screws. The bushings are bronze, 34 millimeters long.

The rods are 265 millimeters long on centers for the 130-millimeter stroke. The forked rods have four 8-millimeter bolts and the center rods have two 10-millimeter bolts. The rod sections are 3-4-inch wide on the front and back side near the top and 1 1-8 inch wide near the bottom; the webs and flanges are all 3-16-inch metal tapered to 1-8 inch at edges, the flanges have a total width of 7-16 inch. The caps are 3-16 inch thick in the thinnest place. The split aluminum rear bearing flange has a fairly uniform thickness of 3-8 inch with a gasket face of 5-8 inch. The oil connection shows plainly on Fig. 8. There are four 10-millimeter bolts, holding the two half flanges together, two inside the case and two outside.

The rear supporting arms and the front ball support are plainly shown in Fig. 5. The front weight comes on the chain case cover which is bushed with cast iron to take the steel starting crankholder which is 1 5-8 inch outside diameter, and terminates in a ball joint 2 inches in diameter.

Crankcase Is Strong

The crankcase is very strong and simple, and is an excellent design for cheap manufacture in quantities. It is plainly shown in the illustrations. The general thickness is a full 3-8 inch, the flanges being the same thickness with a 5-8-inch wide gasket face. The cylinder faces are thickened to 1-2 inch over their whole surface and carry six 12 millimeter studs and two dowels. The front chain cover joint which transmits the weight to the front support has four 12-millimeter studs in reinforced bosses, Fig. 6, and eight 8-millimeter studs.

The cam drive details are shown in Figs. 3 and 4. The crankshaft carries two twenty-tooth pinions, one driving a forty-tooth wheel on the camshaft and the other a twenty-tooth wheel on the oil pump shaft which is just below the main front bearing and runs at engine speed. A forty-tooth twin wheel on the camshaft runs the fan, which carries a fifteen-tooth wheel. The magneto is driven through thirty- and fifteen-tooth chain wheels from the rear end of the camshaft.

All chains are 1-2 inch pitch, outside guide link type, Coventry made; the main camshaft chain is 3 by 4 combination, all the others are 2 by 3 combinations. The chains are all in the front case and all but that driving the oil pump are provided with adjusting idlers. A 3-8-inch pitch or 10-millimeter pitch would be much preferable to the 1-2-inch pitch used.

The cylinder center distances of the 70-millimeter cylinder shown are 3 3-4 inches from 1 to 2, 4 inches from 2 to 3, and 3 3-4 inches from 3 to 4. The valves are 1 5-16 inch over all diameter with a clear opening 1 1-8-inch diameter and a lift of 6 millimeters. The valve stems are 7 millimeters diameter. The valves of the 50-horsepower motor have corresponding diameters of 1 5-8 inches and 1 3-8 inches with 9 millimeter diameter stems. The valves of the 70-millimeter cylinder are 75 millimeters centers to the center line of the cylinders. The exhaust bend, Fig. 11, has an inside diameter of 28 millimeters.

Weight of 1914 Motors

The weights of the 1914 motors are, including carburetor and magneto: 20 horsepower, 462 pounds; 30 horsepower, 550 pounds, 50 horsepower, 693 pounds. It was noted that the distances from the center lines of cylinders 1 to 2 and 3 to 4 on the new 24-horsepower engine was 3 1-2 inches, while the distance between center lines of cylinders 2 and 3 was 3 1-4 inches, or 1-4 inch less. This shows that the engine could have larger bore cylinders by increasing only the center distance to 3 1-2 inches. The cylinder castings are much heavier than the standard European design.

The action of this engine and its condition after hard use are a good argument for the adoption of the general two-bearing, eight-cylinder design it follows. Its condition after 3 years of hard service was easily as good as that of a standard four-cylinder American motor after a similar service for one season. In fact, few four-cylinder motors are found in as good repair as this eight-cylinder.

The origin of the eight-cylinder dates back with the De Dion Co. to 1906 when six experimental six-cylinder cars

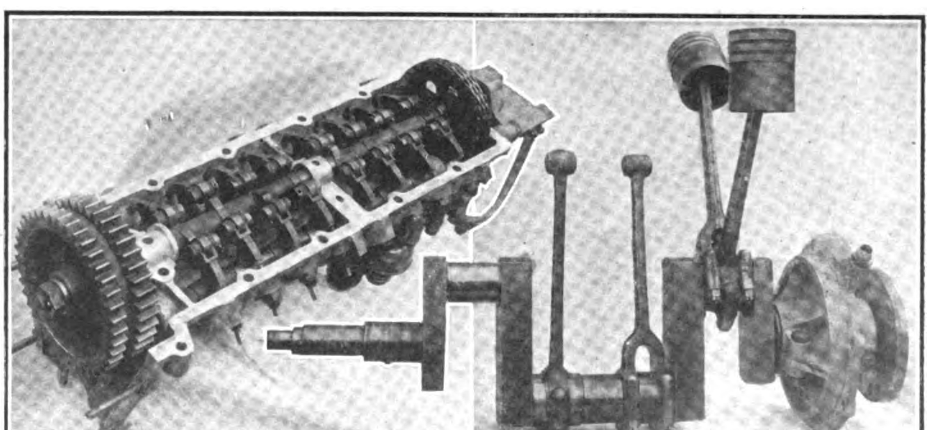

Fig. 7—Left—Camshaft assembly showing cam-roller construction
Fig. 8—Right—Crankshaft with connecting rods partly assembled

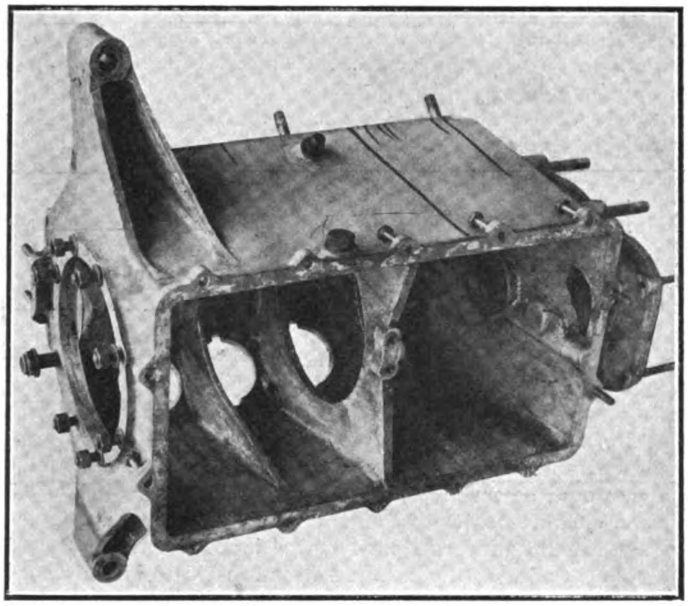

Fig. 9—The crankcase from the bottom showing the method of webbing

and six experimental eight-cylinder cars all of 50 horsepower were built. All of the cars were put on the road and tested for 10,000 miles after which time careful tests and comparisons were made by members from practically all of the departments of the works at Puteaux outside of Paris. The decision was so unanimously in favor of the eight-cylinder cars that the sixes were consigned to storage in a basement until they were finally destroyed by the late floods of the river Seine. This experience is probably unique as the advent of the six-cylinder car in most factories passed without a thought of the possibilities of the eight.

In Europe it cannot be said that the six-cylinder has in any way superseded the four as there are many plants that have never built a six-cylinder and many that have abandoned it with the improvement of four-cylinder design and with the tendency to design lighter and smaller cars for general work. On the other hand, many extremely small sixes are in service, although the performance of the later high-efficiency, counter-balanced four-cylinder models renders them entirely unnecessary. It may be truly said that these small four-cylinder engines and the cars designed with and for them represent the real progress in European automobile engineering for the past 3 years.

Test of Small Four

I started in a serious tryout of this type practically 3 years ago, partly because I did not believe in it and partly because I had to solve some of the manufacturing difficulties of a small car for very little money without an American-sized output to pay for the tooling up. The first year's work resulted in three small cars having 80-millimeter four-cylinder engines. These cars gave the impression of being under-engined except in England, where the roads are particularly good and the hills few and easy. The first remedy was to reduce the axle ratios to slightly lower than 4 to 1 in a car weighing 2,250 pounds, with 34-inch wheels.

Most of the engines of this age and type were designed with a three-bearing crankshaft. When they were new they gave excellent service, but once they began to loosen the bearings, it was difficult to put them back in their original condition. The trouble was naturally sought for in the fact that the engines were proportionately working harder for their size than those in more liberally-designed cars. To make a long story short, it was found to be in the fact that all of the center crankshaft bearings wore out of round on the side furthest from that which would naturally take the thrust of the piston, due to the centrifugal load of the cheeks and pins adjacent to the center bearing. This was plainly shown by the wearing out of the grinder and tool marks, as well as by measurement. The eccentricity of the shaft spoiled the alignment of the bearings whenever they were rescraped and caused the most mysterious roughness. Various expedients, as the stiffening up of the shaft and the crank cheeks and the strengthening of the crankcase and even the use of cast-iron crankcases proved of no avail, and it was not until the advent of the counter-balanced crankshaft that the first of the small type motors was successful. During these troubles much was accomplished by the use of steel and alloy pistons, by the lightening up of working parts generally, by the lengthening of the wearing surfaces of the pistons above the wrist pins and by removing the oil grooves from bearings and generally improving lubricating systems. Some of the engines were of the Knight type; the development of these proved to be of especial interest.

It was not until the year after, that it began to be realized that for the same weight as one of these counter-balance three-bearing crankshaft engines a still more compact two-bearing type could be built as the two-bearing crankshaft is inherently counter-balanced, except perhaps for a very slight projection of the two end cheeks. These two-bearing motors were of a much more refined type than the previous two-bearing motors of France, and on account of their smooth, light running at speeds the sizes were generally reduced to 70 millimeters, and in some cases even smaller bores. These later motors maintained their torque both at very low and very high speeds and gave none of the evidences of being over-worked, which the earlier motors did. It is quite common to see such cars tried out in France at speeds well above a mile-a-minute. I have myself driven them in ordinary touring, covering 35 miles in each hour for long trips.

Small Four Permanent

There is really no question of the success and permanency of the small four-cylinder car in Europe. The problem appears when the 3-inch bore motor is not large enough to fill the bill, as this may be considered as about the limit of assured success in this type, although from time to time larger motors are built.

For my part, I consider the small six-cylinder motor in exactly the same class as the slightly larger four; the same necessity of counter-balance appears if the engine has to be used at high enough speeds to make centrifugal loads a factor. The four-bearing six presents much worse problems than the three in this respect. In the larger motors I have never found the counter-balanced four less flexible, quiet or smooth running than a six-cylinder motor of the same horsepower, either Knight or poppet-valve. The difficulty of balancing the crankshaft is very great in the ordinary six-cylin-

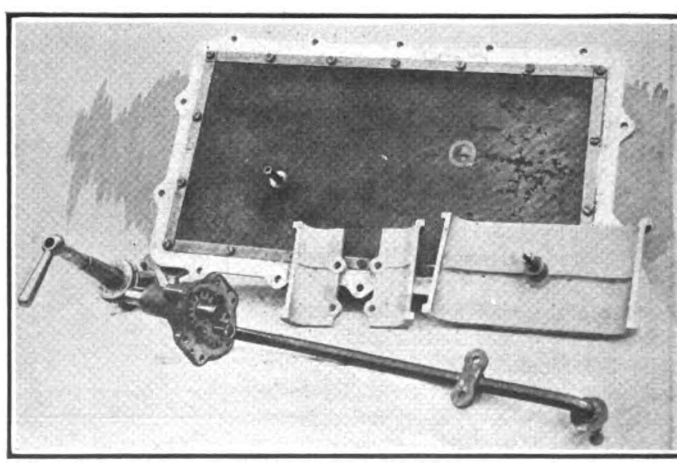

Fig. 10—Crankcase cover and gear oil pump

der and even greater with a counterbalanced shaft due to the springing of the shaft from its own weight during the operation.

What are the problems in replacing a four with a six. A well-known maker with a five-passenger, four-cylinder car wishes to get into the six-cylinder field to supply the popular demand. He is thoroughly satisfied with everything about his car which has been worked down to an economical design in its third season. His six-cylinder motor proved to be 90 pounds heavier than the old four although its flywheel was much lighter. This does not seem very serious. However, he finds it necessary to increase his wheelbase 5 inches to accommodate the longer motor, and here his troubles begin. The longer frame necessitates a deeper section and weights generally go up a little until the tires need to be made a little larger. The motor, moreover, does not show quite the same power or economy as the four-cylinder, although it has to handle the increased weight. The result is that he decides to make it 1-8-inch larger bore and further increase the weight. The motor shows distinct signs of weakness in the crankcase and it is strengthened and made a little heavier. It is thus impossible to make a direct comparison between the old four-cylinder and the newer six-cylinder. A much more satisfactory job could have been made by substituting a more modern four-cylinder engine. Let us suppose that instead of the new six he is willing to investigate the eight-cylinder motor.

Eight Shows Up Well

For his moderate-sized car the eight-cylinder motor of the same capacity can be built with a two-bearing shaft and in less length than the old four-cylinder. It will permit of a slight lengthening of the body space or a corresponding reduction in the wheelbase and weight of the car and even a slight reduction of its own capacity for the decreased weight. These factors together will more than compensate for the slight reduction in thermal efficiency chargeable to the larger cooling area on the greater number of smaller-bore cylinders. This, in turn, will give him the same, if not a greater mileage, per gallon than the original four-cylinder. The tendencies in the six-cylinder design were all against efficiency, as the lengthening of the motor increased the weight and started everything piling up in the wrong direction.

As the cylinders have gradually multiplied, three questions have arisen, first, to what extent does the multiplicity of cylinders and other parts help the flexibility of the motor; second, when does the multiplying of cylinders affect the simplicity and economy of design in general; third, what is the effect on vibration?

The first question of flexibility demands some study. Let us consider a single-cylinder of an engine with cranks 180 degrees apart, as a unit, and take a manograph card of a typical poppet valve motor running at 500 revolutions per minute with the throttle wide open as an indication of the distribution of pressure throughout the working stroke of 180 degrees of the crankshaft when the engine is normally pulling at reasonable speeds. Neglecting side thrust, angularity, friction, and other relative modifying influences and tabulating the pressure times the lever arm for each 15 degrees movement of the crankshaft we will study how much of the stroke of each cylinder is effective.

Degrees of Crankshaft.	Cylinder Indicated Pressure. Pounds Per Square Inch.	Compression Indicated Pressure. Pounds Per Square Inch.	Effective Pressure on Crank.	Relative Lever Arm of Crankshaft.	Relative Turning Moment.
0°	165	0	165	0.	0
15°	210	1	209	.258	54
30°	190	2	188	.5	94
45°	160	3	157	.707	111
60°	140	5	135	.866	117
75°	120	7	113	.965	109
90°	102	9	93	1.	93
105°	88	12	76	.965	73
120°	75	15	60	.866	52
135°	61	18	43	.707	30
150°	50	22	28	.5	14
165°	40	35	5	.258	1
180°	20	60	—40	0.	0

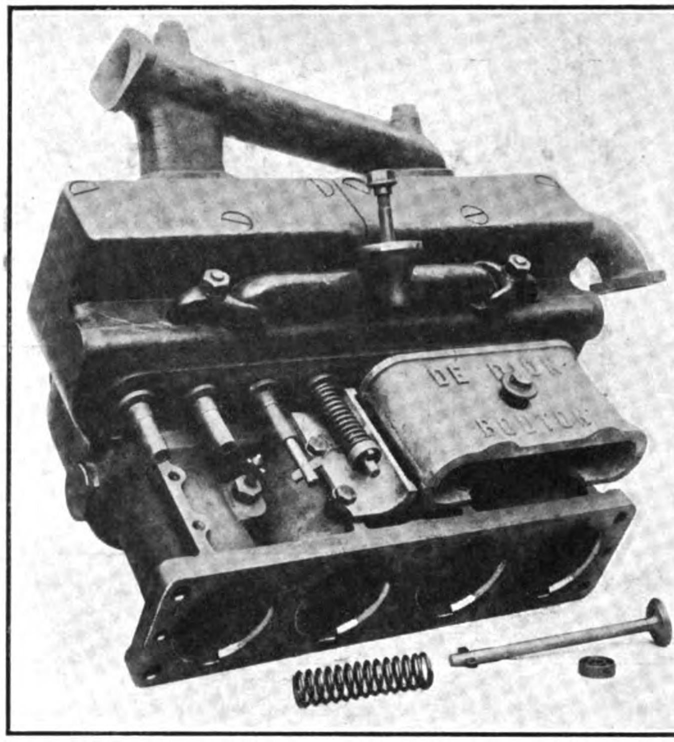

Fig. 11—Right cylinder block with the valves partially removed. The water piping and intake and exhaust manifold are clearly shown

At the upper center or firing point, which may be called, as in the steam engine, the dead center, the pressure contributes nothing whatever to the turning moment of the crankshaft but simply puts the parts under stress and tends to drive the crankshaft out of the bottom of the engine.

After the shaft has turned through the first 15 degrees, the pressures which have decreased but slightly, still contribute little to the turning moment of the crankshaft, on account of the short lever arm presented by the crank at this point.

From 30 degrees to 120 degrees, the turning moment reaches a maximum at 60 degrees and again descends to about the same low point as at 15 degrees. Thus, practically all of the useful work of this cylinder is accomplished between the 30-degree and the 120-degree points of the crankshaft or within 90 degrees. If two or more such cylinders are made to work in succession at 90-degree intervals a fairly uniform turning moment will result although even then the variation in torque amounts to one-half of the maximum.

The smallest number of cylinders that will accomplish this is eight, arranged as a V-type engine. Any smaller number will show a greater variation and depend that much more on the flywheel.

Then the multiplicity of cylinders, up to eight, does help the flexibility of the motor.

Studying the second question: When does the multiplying of cylinders and parts affect the simplicity and economy in general, we find that the eight-cylinder V-type engine with two-bearing shaft has a much simpler crankcase, crankshaft, camshaft and intake manifold than the six-cylinder.

The cylinders are two duplicate bloc castings with an increased number of valves and other parts. The cam rockers are also more complicated and have to be set at 135 degrees as stated in the description of the De Dion motor. The connecting-rods are the real problem, although they present no great difficulty.

The engine is as short as a 4 of the same displacement, providing the crankpin bearing is the same length for a pair of opposite connecting-rods in the eight-cylinder as for a single rod in the four-cylinder.

Two separate designs accomplish this logically and prac-

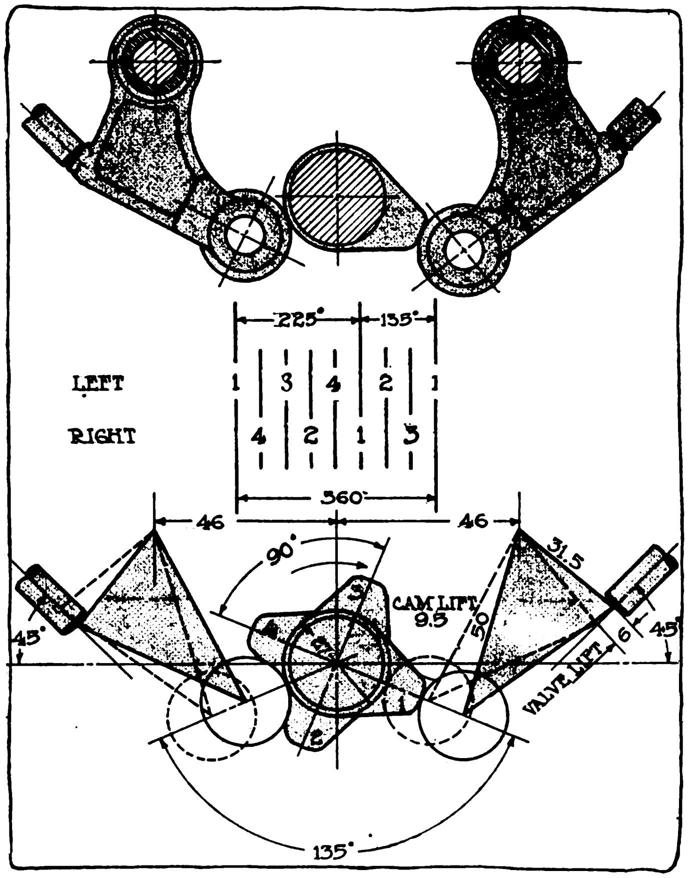

Fig. 12—Layout of valve mechanism showing that the spread between cams of the cylinders firing in sequence must be 135 degrees

tically. In one type, one of the opposing rods is hinged to the big end of the other outside the crank-pin bushing. In the other, as illustrated in the De Dion engine, a single bronze bushing on the crank-pin is used in common for the two opposite rods, one of which is forked to straddle the other. The bronze bushing is held solid in the end of the forked rod and prevented from turning by a dowel in each of its caps, while it is free to revolve or rather rock in the big end of the single-capped rod.

The De Dion crankshaft, Fig. 8, shows No. 1 crank-pin without a rod or bushing, No. 2 with a bushing and a center rod free to rock on it, No. 3 with a bushing dowelled securely in the caps of a forked rod, and No. 4 with both rods.

The placing of rods separately on two crank-pins adjacent longitudinally gives the motor such a length as to destroy its economy of design.

In some instances of four-, six- and eight-cylinder small-bore engines, the bearings at either the top or big end of the rods have been offset longitudinally from the center line of the rod, but these and similar expedients, which result in an unequal distribution of stresses and bearing pressures, do not actually produce economical design; in every such case, a relatively smaller engine designed with all stresses and bearing pressures equalized, will do the same work with equal depreciation and maintenance. I have been connected with many such designs and have kept records of them, covering long periods of operation and test, sufficient to entirely eliminate them from future consideration.

Considering the noise only, the muffling of an eight-cylinder is simple and can be accomplished with a smaller muffler than either a four- or six. In fact, the open exhaust from eight cylinders is not disagreeable. The exhaust valve of any particular cylinder of an eight opens before the exhaust valve of the preceding cylinder has closed, and tends to blow back the exhaust gases of the preceding cylinder to an extent that it is necessary to use either a very liberal muffler or a separate expansion chamber for each block of four cylinders to prevent the next charge from becoming foul with too large a proportion of spent gases. This phenomena appears in many six-cylinder engines where the opening of the exhaust valve exceeds 240 degrees of the crankshaft and has often been charged against the carbureter instead of against the exhaust system. In poppet-valve engines, the area of the valve opening varies directly as the diameter of the valve, for the given lift, while for a given stroke, the cubical contents of the cylinder varies as the square of the diameter; the difficulties of designing the valves of sufficient area of opening, decrease directly as the cylinder bore.

Studying the Third Question of Vibration

Whatever other inertia disturbances, admitted or otherwise, exist in an engine having vertical cylinders, their effect is communicated to the supporting members in the same vertical direction as the stresses due directly to torque reaction. At certain recurring speeds, the periods of vibration due to these disturbing influences, harmonize with those due directly to torque reaction. These speeds are usually designated as critical speeds.

These critical, vibrating speeds can be materially affected by reducing the weight and inertia of reciprocating parts on the one hand and by increasing the number of cylinders and reducing the unit torque reaction on the other, providing the connecting-rods and crankshaft are rigid enough to transmit the intermittent stresses due to inertia and torque, without perceptible spring.

In the V-type motor, having cylinders spaced 90 degrees apart, the inertia disturbances of each side of the engine are still in the line of the cylinder axis. They can be plotted on the sides of a right angle triangle, whose horizontal base or hypothenuse will represent the magnitude and direction of the disturbing stresses due to inertia. These stresses are at right angles to the stresses due directly to torque reaction and can never, at any condition of load or speed, be in phase with them or their harmonics.

This fact applies equally well to any combination of cylinders arranged in a 90-degree V-type engine and explains the success and lack of vibration in the two-cylinder Riley car of England as well as many of the cyclecar engines of this type, in spite of their unequal angular distribution of power.

Advantages of Eight Summarized

The eight-cylinder V-type engine permits equal angular distribution of the power impulses; it has good thermal efficiency, because for a given work, its superior turning moment and more equalized torque permit a smaller engine to be used for the same work; like the small-bore, four-cylinder it permits a short, rigid, self-counterbalanced crankshaft; it has light reciprocating parts with low inertia stresses; it has the immunity from critical speeds enjoyed by all 90-degree V-type engines, and lastly it does not take more space or increase the weight or wheelbase of any car over a four-cylinder engine of the same capacity.

It is surprising how little difference there is either in gear ratio, general design or detail between the modern town car chassis and that eminetly suited for high-speed work. We are gradually beginning to realize that any disturbing forces which mitigate against high engine speeds and spend themselves in vibration are the greatest causes of self destruction, not only in the engine but in every other part of the car.

During the last 6 months the demand from Detroit factories for European experimental high-efficiency cars has been an indicating that considerable study is being applied to this important subject, while the orders appearing on the horizon from the same place since the announcement of the Cadillac eight-cylinder cars threatens to deplete the available stock of eight-cylinder cars which had already been decreased by the European war.

Vanadium—A Vitalizer of Steel

(*Continued from page* 567)

and also nickel-chrome-vanadium steels in which the vanadium content is not less than .12 per cent. An idea of the automobile parts in which this material finds its best use, may be gathered from the accompanying illustration which shows a few representative parts. In one well-known light car it is used for connecting-rods, crankshafts, transmission gears, differential gears, axle shafts, springs, steering knuckles and front axles, besides a number of other small parts subject to wear and shock.

It is not only for vehicles, however, that this alloy has been usefully employed. One of the tools which has the severest duty to perform is the circular saw used for cutting steel rails such as are used for railroads. It is said that these saws cost one-third as much as high speed steel ones and can perform the work as rapidly as the others. Furthermore, the cracking trouble that was experienced with the high-speed steel has ceased with the use of vanadium steel.

Uses a Typical Analysis

It is not alone in automobile engines that vanadium has been successfully employed for internal combustion power plant purposes. The Wisconsin Marine engine has also used vanadium steel crankshafts, connecting-rods, pump shafts and camshafts. The motor particularly mentioned is a 5.25 by 7 six-cylinder marine type and the steel used, a typical chrome-vanadium composition containing not less than .15 per cent. vanadium, .90 per cent. chromium, .65 per cent. manganese and .35 per cent. carbon. The phosphorus and sulphur impurities were kept under .04 per cent. These vanadium steel parts, after their heat treatment, give a tensile strength of 125,000 pounds per square inch. In the automobile racing motors used by the same concern, the same analysis and strength of steel is employed.

Vanadium has been used extensively in brass containing from 50 to 60 per cent. of copper. Its effect is to materially increase the tensile strength of the resulting metal, although in the case of manganese bronze this was at the expense of reduced ductility. The amount of vanadium present is but a trace and micro-photographs show that when the amount of vanadium present is over .5 per cent. there is a slag-like substance which would indicate that above this percentage the vanadium exists in oxidized form.

In a word, we find vanadium used wherever a part is subjected to stresses which would tend to fatigue the metal. The substance which 100 years ago was so elusive that the foremost chemists of the day had difficulty in separating it from its ores, today is one of the factors of making travel safe and economical by increasing the strength of the lightweight parts used in the vital points of vehicle manufacture.

How To Weld Malleable Castings

WHILE the process of autogeneous welding is being used so successfully in all the metal trades, many unsuccessful attempts have been made to weld malleable cast iron, and to those who have experienced disappointment, an explanation of why their efforts failed, with an outline of a method by which these castings can be mended, should be of benefit.

Malleable castings are first made in the condition of hard, brittle, white cast iron and subsequently made malleable by heat treatment. The heating process which converts white cast iron to malleable iron is called annealing, and effects a chemical change in the structure by decarbonization. This decarbonization is nearly complete at the surface and penetrates in a lessening degree toward the center, giving the outside portion the texture of mild steel while the inner portion may retain, in a more or less degree, the qualities of cast iron. When this metal is remelted the carbon is dispersed, and the entire mass reverts to cast iron.

Methods Must Vary with Material

The operator who is used to welding mild steel and cast iron will recall that they are handled differently. That the method used in welding steel to steel would be useless in welding cast iron, or the methods employed with cast iron would be equally unsuccessful with steel. That is practically what he is trying to do when he undertakes to weld a malleable casting. The material is not homogeneous. The bottom portion of the welding being in cast iron, and the top portion in steel, with no definite dividing line between, it is useless to follow the method prescribed for either.

It follows that to successfully mend a malleable casting the process employed must not necessitate the sides of the fracture, that the welding material should fuse at a lower temperature than the casting, and that its adherence, bonding qualities, physical strength and ductility should closely resemble the original casting. After much study and experiment the Vulcan Process Company and their allied interests in Minneapolis are having considerable success in mending broken malleable castings, and a description of their methods will undoubtedly be useful to others who are employed in the metal trades.

In preparing the work for mending, the fracture is chipped away in the form of a V groove with the pointed bottom just coming to the surface on the opposite side, or, if the casting is thick and the opposite side accessible, two grooves are cut with their pointed bottoms meeting in the center. The part surrounding the fracture is then heated with an oxy-acetylene torch to a bright red, and sprinkled with Vulcan bronze flux followed by a few drops of Tobin bronze melted from the welding rod. If the bronze remains in a little globule the work is not hot enough, but if it spreads and adheres to the surface, the temperature is right, and the groove should be quickly filled. It is not advisable to keep the work hot any longer than is necessary, but to make the mend as quickly and at as low a temperature as possible. The behavior of the bronze affords a guide in regulating the temperature. This process cannot be called autogeneous welding, but a malleable casting mended in this way is practically as good as one piece. It has about the same tensile strength and ductility as the original and the process has the advantage of being very quickly performed.—From *The Iron Age*, July 16, 1914.

Rubber Tires Proposed for Street Cars

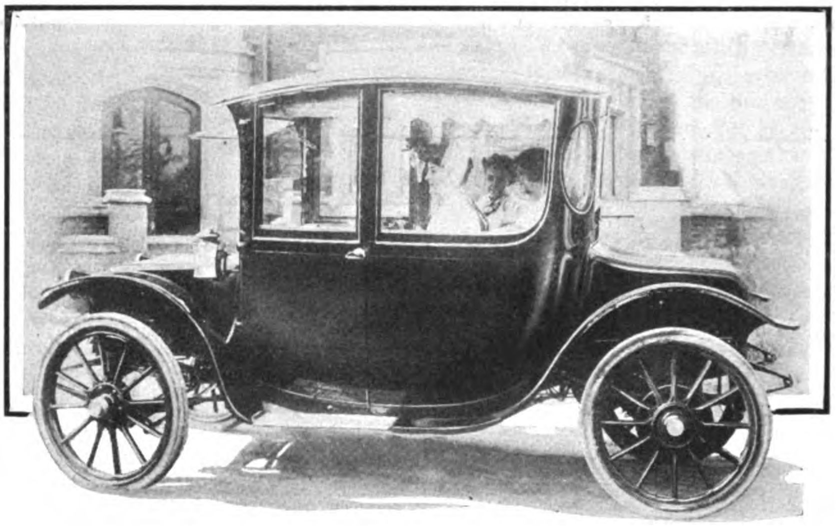
LONDON, ENGLAND, Sept. 20—At the recent session of the Tramways Assn. of Great Britain in Newcastle one of the speakers suggested the introduction of rubber or some other silent material for tires for street cars.

The speaker contended that a properly designed tire for street cars would exceed the life of tires on motor buses and motor wagons, on which a life of 20,000 miles and over was common; that the wear and tear on the rails would be reduced; that the cost of maintenance would be largely eliminated; and that the corrugation problem would be solved.

The question of doing away with noise and vibration, it was contended, was a strong argument in favor of rubber tires. A higher rate of speed could also be attained, which the speaker placed at 20 miles an hour.

More Graceful Lines on New Four-Chair Waverley Electric Brougham

Rounded Corners on Body—Larger Windows With Sashless Frames—Aluminum Body Panels—Chassis Unchanged



New Waverley four-chair Brougham, model 109. Note the rounded corners at the rear and the new shape of battery boxes at front and rear. The windows are larger and sashless

UNDER the model number of 109 the Waverley Co., Indianapolis, has brought out a refined design of electric brougham which incorporates many details new to practice in this field. The new car is fitted with a four-chair body and supersedes the previous body of that type manufactured by this company.

The entire exterior appearance of the body is new. The rear corners are now rounded instead of carried to an edge as in previous models. The battery boxes, still mounted under the front and rear decks, are lower and smaller and have a more delicate curvature. The windows are larger and are now sashless types; oval corner windows are fitted and decorative window shades are factors in the improved and more luxurious appearance of the car.

Four-Chair Seating

The four-chair seating arrangement is continued. By this scheme each passenger has the maximum of knee, shoulder and elbow room and at the same time a wider range of vision. In the construction of the body a new departure for Waverley has been introduced and that is in the use of aluminum. The roof and panels are now of this light metal.

Another feature is the curved sill which gives a low body suspension and yet does not alter the road clearance. The floor is 7 inches nearer the ground than that of the previous design and yet the same road clearance is given.

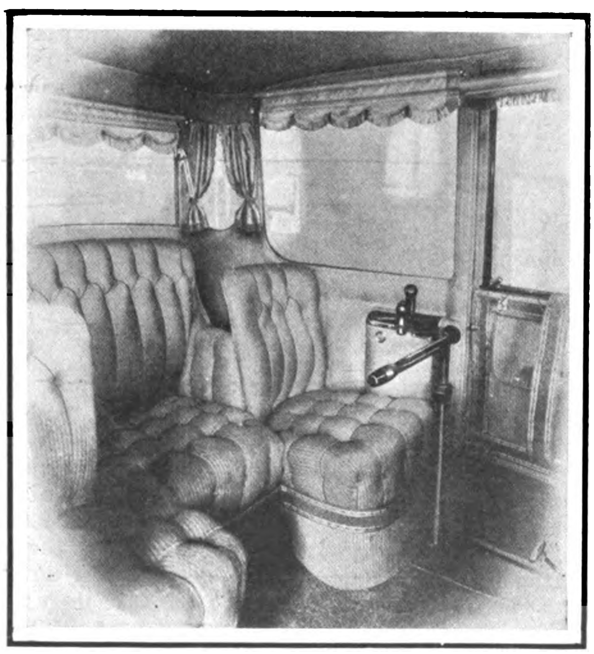
Chassis Details Continued

The same motor is retained, and the same drive and spring suspension. The latter is a feature of Waverley design being a five-quarter elliptic all-around. In the entire spring suspension there are 33 feet of alloy steel distributed among eighty-four spring leaves. Throughout the mechanical parts of the car, standard Waverley practice has not been departed from.

Forty-Two Cell Lead Battery

On the new model the source of power is a forty-two cell eleven or thirteen plate lead battery. Any standard make will be supplied and if the purchaser desires to add slightly to the cost the Edison or Ironclad Exide type will be supplied. The battery supplied is sufficient under ordinary circumstances to carry the car 75 miles.

The Waverley company emphasizes the fact that the ampere-hour capacity is not the true method of measuring the capacity of a battery for purposes of judging the distance that it will propel a car. The true criterion is the watt-hour capacity. This is reached, in the case of a lead battery which measures about 2 volts to the cell, by multiplying the number of cells by two and multiplying this result by the ampere-hours capacity of the battery.



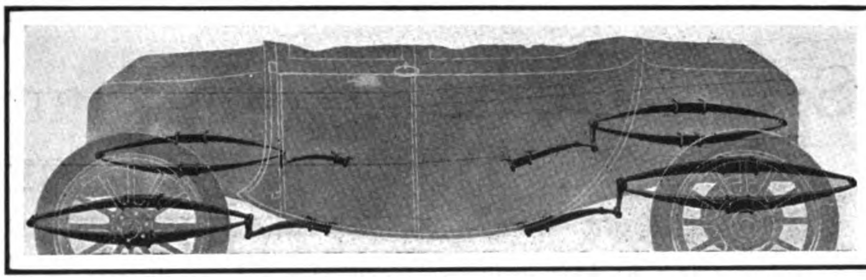
Interior of new four-chair Brougham with left drive. The decorative window shades are a feature

In the case of the Edison battery the voltage runs about 1.2 to the cell. For this reason the number of cells will have to be multiplied by that figure in calculating the capacity of an Edison battery. In fitting the Edison battery at the extra price the company supplies the 60-cell type.

The batteries are carried at the front and rear. The battery boxes are covered by the sloping decks which are rounded off to give a harmonious design. In order that no acid can reach the paint through spilling of the liquid, the battery compartments are lined with acid-proof material.

Knife-Blade Controller

The flow of current from the battery to the motor is regulated through a knife-blade type



Five quarter elliptic spring suspension which gives all the advantages of the full elliptic and the cantilever, it is stated

of controller. As the handle of the controller, by means of which the driver regulates the speed of the car, is pushed forward, the knife blade switches are picked up one by one. Each blade of the switch is of brass, and the contact is made on both sides of the blade by means of copper blocks which are sprung apart on the entrance of the blade. The springs which hold the blocks tightly against the knife blade are of the finger type and are made from phosphor-bronze. A Yale lock is fitted on the controller handle to guard it against theft. The car cannot be started on any but the lowest speed on account of an interlocking device. The electrical connections are made without any break in the circuit giving a continuous smooth acceleration.

Medium Speed Motor Used

A medium-speed, four-pole, series-wound motor is employed in the new Waverley as in all the other models of this make. The nominal speed of the motor is 1,500 r.p.m. This speed has been selected because it is high enough to furnish the high torque necessary in pulling the car through a difficult stretch of road and yet it is not of such high speed that there are material losses through the necessity of a large gear reduction.

The motor has a nominal voltage of 80 and the battery of 84. This allows for a drop of 4 volts in the line between the battery and the motor. As the entire system, especially as regards the controller has been designed to keep the current loss through resistance at a minimum, this allows a good factor of safety.

The motor is suspended from the body just forward of the rear axle and as will be seen from the illustration there are two reductions. The first is through a silent chain from the armature shaft of the motor to a shaft parallel with the rear axle. From the latter shaft the drive is transmitted by means of a silent-herringbone gear to the rear axle. The reduction is such that at 1,500 r.p.m. of the motor the car is traveling at 20 miles an hour.

Floating Rear Axle

The rear axle is floating, the shafts being of 3.5 per cent. nickel steel, heat-treated. One end of the axle shaft floats in the differential and the other is connected to the wheels by a clutch through which the drive passes. The short shaft between the rear axle and the motor is merely a driving member as are the axle shafts. They are not called upon to bear any twisting torque strains. The differential gears and the herringbone drive can be exposed to view by the removal of cover plate from the housing as shown in the illustration.

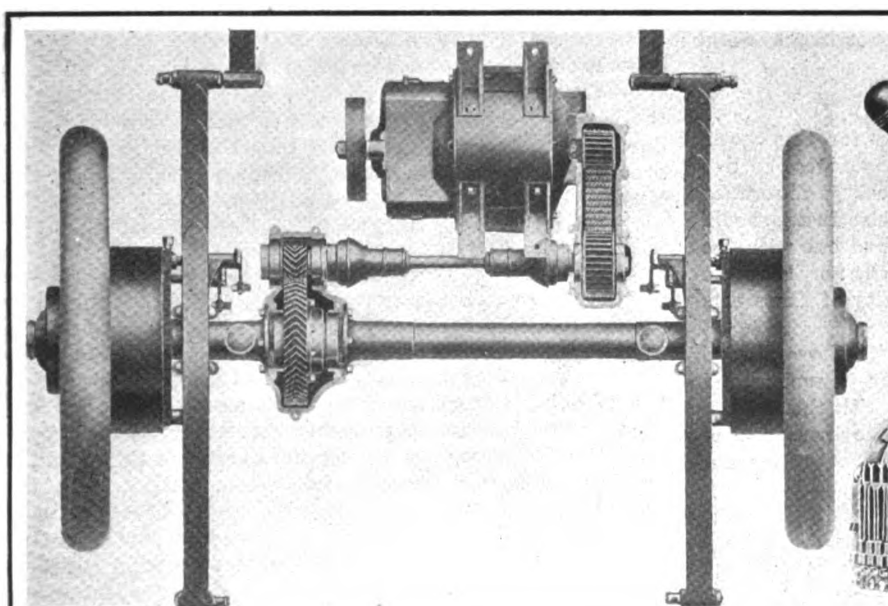
The front axle is an I-beam section of one-piece, drop-forged, steel. The spring pads which carry the full-elliptic springs are forged integrally. A rather unusual feature in axle work is the outward slant given to the steering knuckle and the downward tilt, to counteract this given the spindle. This results in a semi-irreversible steering gear as there is a greatly reduced tendency of a road shock to swing the front wheel about the tilted pivot pin. The steering connections are ball and socket all through. The joints are provided with coil springs to absorb the shocks and they are universal in action. The unassembled view of the axle illustrates the parts.

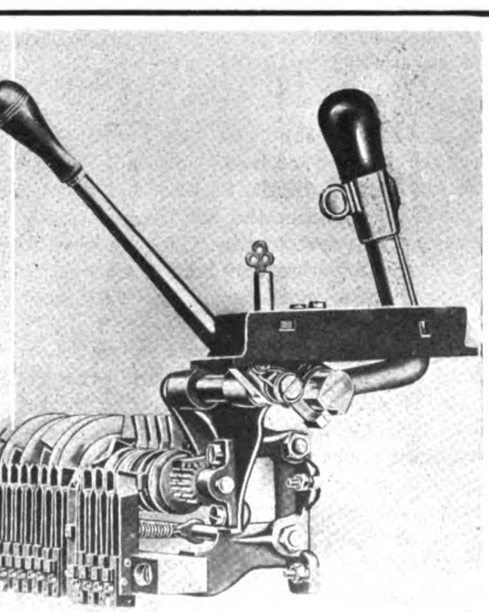
Trussed Wood Frame

The frame of the Waverley car is a patented feature which ingeniously furnishes a large amount of strength and at the same time forms a good support for the body. A trussed hardwood beam is used. This is brought close to the ground in a graceful sweep providing an entrance low to the ground and yet not lowering the part of the body which supports the motor to such an extent that the road clearance is cut too low.

Both the front and rear wheels are carried on the Timken bearings. Dust caps are fitted over the outside of these

(*Continued on page* 597)





Left—Power plant showing connection of motor with floating rear axle. A double reduction drive is used, the first being through a silent chain and the second through herringbone gears

Right—Controller used on new Waverley. A Yale lock is fitted to guard against theft

Thinks Set of Gears Better than Extra Battery Cells for Starting

The Automobile Engineers' Forum

Engineer Likens Starting a Motor to a Study in Leverages, the Starter Being the Lever and the Gear Ratio the Fulcrum Location

DAYTON, O.—Editor THE AUTOMOBILE:—The question of relative merit of the 6-volt and 12-volt electrical systems for automobiles cannot be answered by stating that either is best. As Mark Twain said, "It is difference of opinion that makes horse races."

The 12-volt proposition at the present time seems to have its strongest supporters among those manufacturers who use a very low gear ratio between the starting motor and the engine, and must, therefore, have greater torque than would be necessary were a higher gear ratio used.

Study in Leverages

Starting an engine can be considered as a simple study in leverages. In the choice of a long or short lever to move a given weight, you must have a heavier short lever and a heavier pull on the end of it than if your lever is longer. In the case of starting an automobile engine, the lever is the starter and the location of the fulcrum is the gear ratio. You can take either a short heavy lever, which is a low gear ratio motor, and a heavier battery to pry the engine loose and keep it moving; or you can use a reasonable gear ratio—a small machine—in which case a light, low voltage battery is ample.

This company is not in the habit of entering any discussions of this type, as we believe no useful interests are served in argument. Our apparatus for any automobile is designed to give the best operating efficiency for that particular case, and we usually design a gear ratio which will crank under the most unfavorable conditions at a good starting speed.

Gears Preferable

If there must be complications in the system, we believe a set of gears, which are idle except at the moment of starting, to be far preferable to a multiple cell battery in which the extra cells are always to be reckoned with in the added space and weight necessary and the additional care which they demand, because for a given weight of battery the fewer the cells the greater the efficiency, and the less care they require.

As far as the lighting proposition goes, the argument is all in favor of the lower voltage.—W. A. CHRYST, Chief Engineer, Dayton Engineering Laboratories Co.

Considers Two-Wire System the Only Logical One

BRONXVILLE, N. Y., Editor THE AUTOMOBILE:—Our company makes a specialty of supplying its lighting and starting system with all the wiring necessary for wiring a car, with the plugs on the ends of the wires, the wires cut to proper length, connected to the switch, etc., so all that our customers have to do is to put these wires in place and fasten the switch to the dash.

Two-Wire System Never Fuses

We will not supply a single wire system for this work, because of the fact that a ground in the single wire system means a short circuit, and as a consequence it is absolutely essential that either the two-wire system or else fuses, should be used. No system that we have ever turned out with the two-wire copper return has ever been fused, nor have we ever known or seen a case where the necessity of fuses was apparent.

The advocates of the grounded return system have always claimed that it was simpler, and was easier to understand than the all copper circuits, but I disagree with this. I believe that any owner will find it as simple to trace a two-conductor cable from his battery to his switch, as to trace a one-wire cable.

The introduction of the fuse immediately entails complications that make the grounded return system entirely too complicated for the average users of motor cars.

Four Reasons for the Two-Wire System

I consider the two-wire system preferable for the following reasons:

1—It is safer—because on account of the elimination of fuses, a single ground will not immediately produce a short-circuit, which will blow out fuses and put out the lights when the car is being driven.

2—It is simpler—on account of the elimination of fuses and fuse contacts which become loose, etc.

3—It is cheaper—on account of the elimination of fuses.

4—The entire history of electrical engineering records the use of ground return systems in each branch of the industry when in its infancy, and then the elimination of the ground return and the use of a copper return finally.—L. KEBLER, President Ward-Leonard Electric Co.

Thinks Lower Upkeep Offsets Extra Cost of Oversize Tires

AKRON, O., Editor THE AUTOMOBILE:—We acknowledge receipt of your letter of the 16th inviting an expression of opinion from us on oversized tires. There has been so much misinformation published regarding so-called "oversized tires" that we are taking the liberty at the outset, of defining the term "oversized tire" when used by us by this statement.

By "oversized tire" we mean a tire that fits a rim of accepted standard size in spite of the fact that the tire is so made that it is 1-2 inch wider in cross sectional diameter than the regular sized tire for that rim. To be specific, we regard a 33 by 4-inch tire as the "oversize" for a 32 by 3 1-2-inch tire. With us variance between a number of different

32 by 3 1-2-inch tires would not constitute one of them as the standard and some of such tires be regarded as "oversize" and others by the same token as "undersized."

It is not promised for oversized tires that they will give more mileage, although in theory perhaps, they should do so. This is due to the fact that we regard mileage as something which is largely within the control of the tire user. We think most drivers are careful of their tires and wear them out rather than otherwise. Consequently, the oversized tire has the opportunity in most cases of establishing its superiority over the regular sized tire.

The strongest defence of the oversized tire that we know of is the fact that no case has ever come to the writer's attention or to the attention of any other tire man with whom I have had the pleasure of discussing this question, of a person who once having used the oversized tire went back to the smaller regular size.

This, we think, conclusively establishes that the oversize is the more satisfactory tire and this satisfaction must, we think, be based largely on serviceability.

A Greater Margin of Safety

The oversized tire having a larger area, manifestly has more material than the regular sized tire and a greater carrying capacity. These two factors result in a greater ability to withstand abuse, ability to do its work with less distortion of the tire, the probability of minimizing trouble from cuts, bruises, etc., and a greater margin of safety. In addition, oversized tires require less air pressure to properly carry a given load and this affords greater riding comfort to the occupants of the car and less jarring and jolting of the car proper and a corresponding reduction in the loosening of nuts, bolts, motor mechanism, etc. This again results in lower car up-keep, which we are satisfied if closely analyzed, will more than offset the increased cost of the oversized tire over the cost of the regular sized tire.

The Other Side of the Argument

The possible disadvantages of the oversized tire are its additional first cost and the possibility that if the tire is injured so badly as to be beyond repair, the net loss is greater on account of the relatively greater investment.

All things considered, however, we have no hesitation in urging our customers who are not getting satisfactory service out of regular sized tires to use the oversize; and as previously stated, no case has come to our attention of the return of such person to the regular sized tire.—DIAMOND RUBBER Co.

Decisions of the Courts—Must Sue Repair Man

By GEORGE F. KAISER

REPAIR man is responsible alone when a collision occurs after a car has been turned over to him for the purpose of being repaired and tuned up.

While an automobile was in the possession of a repair man for the purpose of being put in order and was being tested by him, it collided with a motorcycle. The motorcyclist was injured and brought suit against the owner of the car. The latter showed that he had bought the car for the purpose of speculation, intending to sell it again. It was an old car and it had been turned over to the keeper for a small garage who was to put it in order. He was to be paid for his services and, if he was able to sell it for more than the owner's asking price, he was to receive a commission in addition. The repair man worked on the car at odd times for a month and finally took the car out one Sunday to test it. This was without the knowledge of the owner, who had given him no instructions or suggestions regarding the testing of the car. At this time the collision resulted.

The Court said that when a man turned a car over to a mechanic for repairs and exercised no control over it nor over the mechanic, if the mechanic, finding that a test is necessary, tests the car and injures someone, the owner is no more responsible than if the mechanic took it without any authority and the injured party must seek recourse against the mechanic.—*Segler vs. Callister*, 139 *Pac.* 819.

$3,500 Judgment Affirmed

Connecticut Court says that, when a collision occurs between an automobile and a wagon, and the person riding on the wagon is injured, the owner of the car is responsible in money damages, if she allows another to act as her agent in giving the chauffeur instructions.

This collision resulted while the car was being driven by a chauffeur under the direction of the owner's 18-year-old daughter, who was taking two girl friends out for a drive. After going to a near by town, they returned home and the daughter directed the chauffeur to drive home to his own house for supper and to bring the car back again. The chauffeur went home, had supper and then, coming back, the collision resulted.

The Court said that the mother was not liable, merely because of the relationship of mother and daughter, but because she had given the daughter authority to direct the chauffeur and had told the latter that he was to take orders from the daughter in the absence of direct orders from herself and stated the rule of owner's liability to be that he is liable "for all acts done by a servant in obedience to the express orders or directions of the master, or in the execution of a master's business within the scope of his employment and for acts in any sense warranted by the expressed or implied authority conferred upon him, considering the nature of the services required, the instructions given and the circumstances under which the act is done; for acts which are not within these conditions the servant alone is responsible.—*Carrier vs. Donovan*, 89 *Atl.* (*Conn.*) 894.

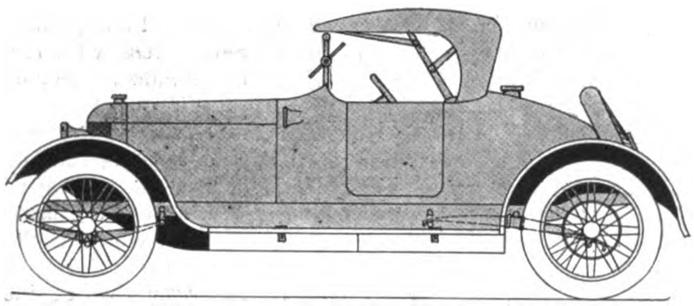
Judgment for Children

New Jersey Court holds that when a person is placed in a position of peril, as the result of another's negligence, if he makes a mistake of judgment in the moment he has to decide, he is not guilty of such negligence as will bar him from recovering judgment for injuries from the other negligent party.

A suit was started by the representatives of three adult children for their mother's death. The mother was killed while crossing Atlantic avenue in Atlantic City, being run down by an automobile which was going along at great speed.

No Time To Decide

The Court said that the judgment for the representatives of the deceased against the motorist was proper as, where a person in a moment and position of peril, which is the result of another person's automobile charging down upon the person at great speed, makes a hasty decision and does not do the thing which would probably have been done if more time were given for consideration, is not so at fault as to be prevented from recovering damages from the motorist, guilty of reckless driving.—*Wescoat vs. Decker*, 90 Atl. (New Jersey) 290.



The Rostrum

Puts Old Shoes Over New

EDITOR THE AUTOMOBILE:—I noticed a communication in your issue for September 10 from W. B. Duling, Back Bay, Wis., regarding the use of old tires over new ones, and I thought you might like to hear other readers' experiences with them. Using old discarded tires in this way has become a general practice in this section of the country. All, of course, do not use them, but a great many do to good advantage.

To use the old tires, Fig. 1, do not cut the head off. You have to take the casing off the wheel and insert, by hard work, into the old casing and apply both to the wheel at one time. Then you have practically a puncture-proof tire and one that is long lasting. It is desirable to have good inner tubes on account of it being too much trouble in changing in case an old tube gives away. So far as heat and sand are concerned, it does not seem to amount to anything. The old casing fits so tightly over the good one that there is no slippage and it protects the good tire from road heat. Some drivers, however, cut slits in old casings around the whole tread from bead to bead. They say it makes them easier to apply, as well as to allow ventilation. These slits are cut about every 4 inches and about 1-2 inch of the material taken out. I know a traveling salesman who covers a vast territory, is all the time on the road, and he used this equipment for over 2 years and never has had a puncture.

Coolidge, Texas. W. M. PRICHARD.

From Illinois to Texas

Editor THE AUTOMOBILE:—Please give through THE AUTOMOBILE the best route to San Antonio, Texas, going by way of Kansas City and Webb City, Mo.?

Winchester, Ill. WILSON COULT.

—First go to St. Louis, and then through Columbia and Marshall to Kansas City, 350 miles. Then turn southwest to Arkansas City, 232 miles, through Emporia and Florence. The next large city is Dallas, 417 miles, through Oklahoma City and Dennison. Turn west to Fort Worth, 33.2 miles and then go south to San Antonio, 354.4 miles, through Waco and Austin.

Wants to Use Car Motor in Boat

Editor THE AUTOMOBILE:—1—What would you consider the necessary changes in order to make a 30 horsepower White automobile engine give good service as a motor boat engine?

2—What kind of a propeller must be used?

3—Would it be advisable to lower the compression by putting a fibre gasket under the cylinders?

4—Would it help this engine any to change the valve timing, and if so, how could this be accomplished?

Montgomery, Ala. R. S. B.

—1—This motor should give satisfactory service without any changes. Proper cooling arrangements should be made, however. The flow of water through the cooling system should be regulated so that the temperature of the water issuing from the motor will be at a temperature of about 180 degrees Fahrenheit.

2—The type of propeller depends on so many things that it is impossible to say what kind or size to use. Write to the propeller manufacturers stating the size of the motor, its speed, the size of the boat, including length, beam and draft; the weight of the boat, and give a general idea of the lines of the hull.

All these matters have an effect on the size, shape and speed at which the propeller is to run. For instance, if the boat is so large that this motor cannot possibly run it more than 10 miles per hour, the propeller cannot be operated at as fast a speed efficiently, as if the maximum speed of the boat were 20 miles per hour.

3 and 4—No.

Formula Should Consider Stroke

Editor THE AUTOMOBILE:—I was very pleased to see that on page 407 of THE AUTOMOBILE for August 27, 1914, you recommended the horsepower formula $\frac{D^2 S N R}{15{,}000}$. For a number of years in the hospitable columns of THE AUTOMOBILE and *Motor Age* I have been advocating a similar formula having for its divisor 12,000. The results given by the $\frac{D^2 S N R}{12{,}000}$ formula which I devised in 1906 are somewhat higher than those obtained from the rating which you recommend, but are probably nearer the actual output of the fairly efficient motors of today.

As regards simplicity the $\frac{D^2 S N R}{12{,}000}$ rating scores even over the now discredited S. A. E. formula $\frac{D^2 N}{2.5}$. For example, if the power developed by a four-cylinder motor at 1,000 revolutions per minute is desired, the formula becomes merely $\frac{D^2 S}{3}$; for a six-cylinder motor under the same conditions, $\frac{D^2 S}{2}$; etc.

London, England. JOHN JAY IDE.

No Free-for-Alls in 1913

Editor THE AUTOMOBILE:—1—Could you tell me the name, date, place, distance, cash prizes, and who won in every free-for-all race held in the U. S. during 1913?

2—When and where will the American Grand Prize be held in 1915?

3—What are the rules governing a free-for-all race? Would a steam automobile, a motor cycle, or a tri-car be allowed to compete in one?

4—Why does THE AUTOMOBILE, editorially, favor races with a limited piston displacement?

Roebling, N. J. SIEGFRIED ROEBLING.

—1—According to THE AUTOMOBILE for this year no free-for-all events of importance were run. Possibly some small races of this type were run but the results of these are not obtainable.

2—The Grand Prize race will be held on March 7 at the Panama Pacific exposition, San Francisco, Cal. The race will be on the exposition grounds.

3—A steam automobile would be admitted, but a motorcycle, or a tri-car would not, unless it had a reverse gear. The rules state, "A Non-stock free-for-all race is open to any gasoline car which complies with the definition of motor car, without restriction as to piston displacement, price or quantity produced." And a motor car is defined as, "A vehicle of three or more wheels propelled by a self-contained mechanical means, fitted with at least two brakes, operated independently of each other and a motor-driven reversing mechanism.

4—We favor races with limited piston displacement because these contests force the maker to obtain greater efficiency and power from a motor of given size and this leads to improvements in stock car design. Furthermore, the racing motors of limited piston displacement are more nearly the size of stock car motors and the lessons learned in racing can often be directly applied to stock car practice. For instance, if it is found that a connecting-rod of a given size and shape stands up satisfactorily in a racing machine, the same rod might be used in a stock motor, where the greatly reduced strains would make it unlikely that one of these would ever break in service.

Remedy for Slipping Clutch

Editor THE AUTOMOBILE:—One of our customers, who owns a 1910 model Buick has had trouble with the clutch slipping and we write to ask if you could suggest anything to remedy this.

Williamsport, Pa. THE HARER-WURSTER CO.

—The slipping clutch may be due to a worn facing or weak spring—or in the case of the 1910 runabout which is equipped with a planetary gearset, the leather may be overlubricated due to grease leaking in through the worn transmission bushings. Remove the facing, clean it well and if it is made of leather soak it in neat's-foot oil for 24 hours before replacing.

To Locate a Loose Push Rod

Editor THE AUTOMOBILE:—What is the easiest way of locating a loose push rod?

Sugar Grove, Ill. H. V. SMITH.

—A loose push rod can easily be found by feeling with the hand. If there is too much clearance between the stem and the top of the rod, it can be ascertained by rattling the push rod and if this is the case, it should be adjusted, preferably while the motor is warm. Make the space about 1-100 inch or the thickness of a sheet of writing paper.

If the rod is worn in the guide, a certain amount of lateral movement will be noticed when force is applied to the rod by the hand.

Arched Manifold Reduces Loss

Editor THE AUTOMOBILE:—What is the reason for having the intake manifold arched as in the Mercedes cars used in the recent Grand Prix race in France, and in the Mercedes which De Palma drove at Indianapolis?

2—What kind of rings are used on the rotary valve of the Jaeger motor? Are they pinned? If so, are they fastened to valve or casing?

3—What is your opinion as to the reliability of the Van Kueren motor? Does this motor keep good compression at all times, and is there bearing enough between the ports and the port in the top of the cylinder to maintain compression after the motor has been used for a considerable time?

4—Is there any rule for determining the compression pressure for a certain size motor?

5—What should be the size of valve openings in a rotary valve for a motor 3¾ by 5, four-cylinders, compression 85 to 90 pounds, speed, 2,500 or 3,000 revolutions per minute, cone-shaped compression chamber?

6—What power should it develop?

7—What should be the timing of such a motor?

East Marion, L. I. W. FURST.

—1—Apparently the arch is to allow the carbureter to be carried high and at the same time provide a passageway without sharp curves.

2—This is unobtainable.

3—We have not seen this motor in service and therefore cannot say whether it retains its compression.

4—The compression pressure does not vary with the size of motor but is independent of it. The compression pressure depends on the ratio of clearance to piston displacement. If these two facts are known, the compression may be calculated, assuming that the rise in pressure follows the adiabatic law, that is, no heat is given to the charge or taken from it during compression. This is approximately correct.

$$\text{Compression press.} = \left(\frac{\text{clearance vol.} + \text{pist. disp.}}{\text{clearance volume}}\right)^{1.4} \times \text{atm. press.}$$

By compression pressure is meant the absolute pressure, which is equal to the gauge pressure plus 14.7 pounds. The volumes are expressed in cubic inches and the pressures in pounds per square inch.

5—There is very little data on this subject but we would advise making the valve ports with an area of at least 3 square inches, and larger if your motor design will allow.

6—The power should be 56 according to the formula,

$\frac{D^2N\,S\,R}{15{,}000}$, when the motor is running 3,000 per minute.

Where D=bore in inches, N=number of cylinders, S=stroke in inches and R=revolutions per minute.

7—Intake should open 20 degrees after top dead center and close 40 degrees after lower dead center. The exhaust valve should open 60 degrees before lower dead center and close 15 degrees after top dead center.

How to Adjust Hudson Axle

Editor THE AUTOMOBILE:—Will you please describe how to adjust the rear axle parts on the Hudson 37?

New York City. L. W.

—The adjustments on this axle, which is illustrated in Fig. 2, are as follows: The outer pinion shaft bearing is adjusted by means of the lock nut A, while the inner pinion

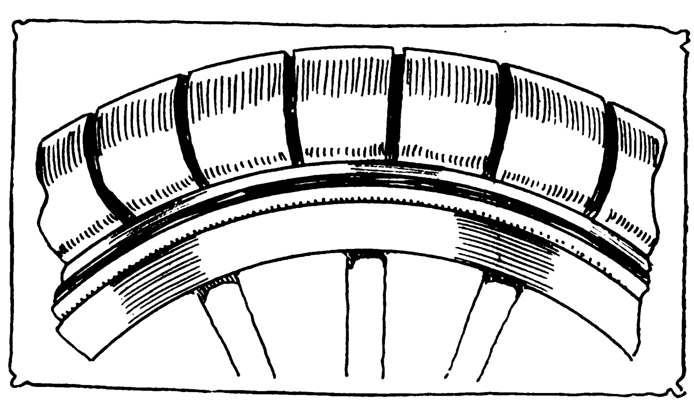


Fig. 1—One method of placing a worn out casing over a good one. In this case slits are cut in the outer casing at intervals of 4 inches to give a non-skid effect

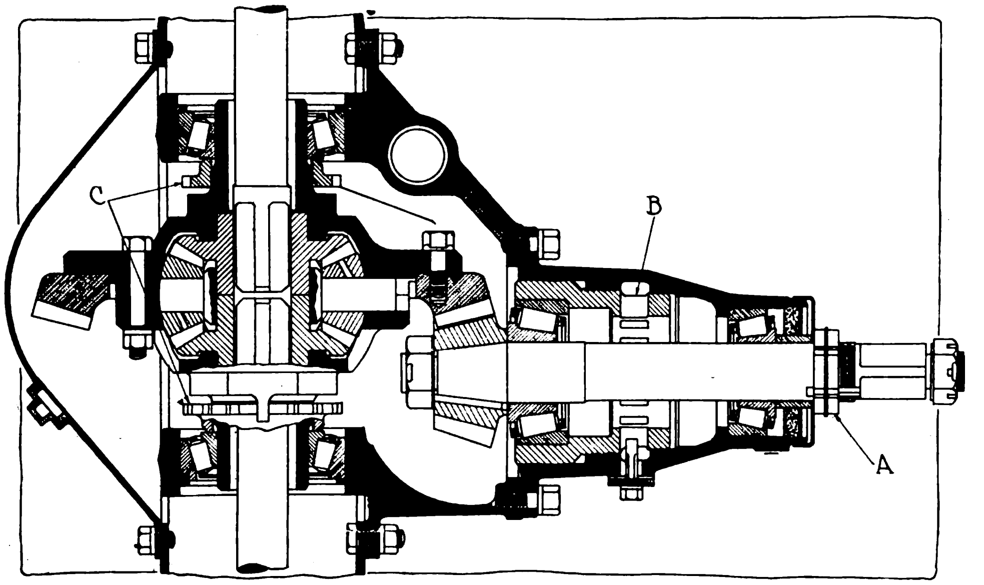

Fig. 2—Hudson model 37 axle showing points of adjustment

shaft bearing is held in a cage B which is capable of adjustment by screwing to the right or the left. It is positively locked by a set screw.

The differential bearings are adjusted by means of the nuts C.

The wear in the drive pinion may be taken up by means of the adjusting nuts A and B, the object being to set the pinion closer to the gear, in order to compensate for the wear. Play in the differential is removed by similarly adjusting the nuts C.

Comparison of Long and Short Strokes

Editor THE AUTOMOBILE:—1—A friend and I had a dispute over long and short stroke motors. Which motor develops the most power, one with an equal bore and stroke, or the one with the longer stroke than bore; both having the same displacement?

2—Which will give more power when driving over hills?

3—Which will give more speed.

4—Which will be more economical?

5—Can you supply an illustration in which a person will be lifting a weight with a two foot lever, and another with a ten foot lever, to these motors?

6—Would you place the person at the short end or the long end of the lever to bring out the point.

7—If I stand about 3 feet away from fender of car, and touch spark plug with a piece of metal when motor is running, I receive a shock. Can you explain how it makes a circuit through the pneumatic shoes?

Verona, N. J. THOS. P. LAMBE.

—1—Within reasonable limits there is very little difference between the two types as regards the power developed.

2 and 3—At equal motor speeds the power and maximum car speed would be the same.

4—Somewhat greater economy may be obtained from the long-stroke type.

5 and 6—The question of leverage does not enter into the problem at all. Let us consider a 4 by 4-inch motor and a 3.5 by 5.25 motor, the former having a displacement of 201.1 cubic inches and the latter 202. The former is square and the latter may be called a long-stroke motor. Under the same conditions, this includes temperature of combustion chamber walls, compression, and time of ignition, etc., almost the same pressure will be generated by the combustion of the charge. In both cases the expansion of the gases will be brought to about the same point before the exhaust valve is opened, and therefore the mean effective pressure in both instances will be practically the same. It can be assumed to be 90 pounds.

The work developed during the stroke is equal to the total average pressure on the piston during the stroke multiplied by the distance through which it moves. Therefore, power per stroke = area of piston $\times$ average pressure per square inch $\times$ length of stroke.

The area of the 4-inch cylinder is $4^2 \times .7854$, or 12.55 square inches, while the area of the 3.5 inch cylinder is 9.6 square inches.

Therefore the total amount of work done in each case is,

Work $= 12.55 \times 4 \times 90 = 4{,}500$ inch pounds.

Work $= 9.60 \times 5.25 \times 90 = 4{,}500$ inch pounds.

7—You experience a shock for the reason that the voltage is high enough to force a current through your body, the ground and up through the tire to the motor again, and thus the circuit is completed. The rubber is not a perfect insulator; probably because there is always a certain amount of moisture in it. The quantity is small but sufficient considering the great voltage.

Reasons for Motor Knocking

Editor THE AUTOMOBILE:—My Ford car knocks when running free. It has been overhauled twice. Has new block, crank shaft, pistons, camshaft and timing gears. In fact it has a new engine, added piece by piece. The knock is said by an expert Ford mechanic, to be in the crankshaft and camshaft gears. It does not knock when working hard. The position of the spark does not affect it, but a certain notch on the throttle lever brings it out strongly. What can you suggest?

Portland, Me. WALTER E. TOBIE.

—It is impossible to state where this knock is but it does not seem likely that it is in the timing gears. Possibly the cause is a loose bearing, due to wear or carelessness in assembling the motor. Examine the main connecting-rod, camshaft and wrist-pin bearings for this trouble. See that the compression is good in all the cylinders and that the valves are tight and seating properly.

Speeds of Various Cars

Editor THE AUTOMOBILE:—1—Kindly give me in the Rostrum the following information: The highest speed that can be made with each of the following cars, fully equipped with touring car bodies.

Packard, 38.

Peerless, 38.

Franklin, 30.

2—Also, kindly give gear ratios of each.

Matador, Texas. L. B. HUBBARD.

—1—The speeds of these cars are as follows: Packard, 67 miles per hour; Peerless, 60; and Franklin, 55.

2—The gear ratios are: Packard, 3.53 or 3.93, at option; Peerless, 3.56 to 1; Franklin, 3.69 to 1.

Brush Motor Will Run Generator

Editor THE AUTOMOBILE:—Please let me know what you think of this outfit. A Brush engine from a Brush car to run a 3 K.W. generator direct connected to a 110-volt dynamo.

Please let me know if this engine will run it direct connected satisfactorily and without any flickering.

Eunice, La. K. MOOSA.

—If you operate your generator at full capacity at any time and the speed of the generator is in the neighborhood of 1,500, the motor will hardly develop enough power to allow of it being direct connected.

It is a simple matter, however, to do it by means of a belt.

Your motor will run this generator satisfactorily, providing the belt pulleys are the proper size and a good governor is fitted. The flickering of the lights depends entirely on how smoothly your motor runs under varying load conditions and this in turn is affected by the sensitiveness of the governor and the size of the flywheel.

You have not given enough details for us to determine the size of the pulleys or advise you as to the other details of the installation. Probably your generator runs at a speed of about 1,500 revolutions per minute. The motor should be run at such speed that an overload of 50 per cent. or a 3 K. W. can be carried. This is approximately 4 horsepower.

Since the bore and stroke are 4 by 5 inches, the motor will produce this horsepower at 750 revolutions, according to the formula:

$$\text{Horsepower} = \frac{D\,S\,N\,R}{15{,}000}$$

or

$$R = \text{revolutions per minute} = \frac{\text{horsepower} \times 15{,}000}{D\,S\,N}$$

Where D = bore in inches
S = stroke in inches
N = number of cylinders, which is 1

Substituting, we have,

$$\text{revolutions per minute} = \frac{4 \times 15{,}000}{4^2 \times 5 \times 1} = 750$$

It must, of course, be borne in mind that the solution given by this formula is not absolutely accurate, but it should be near enough. The only sure way to determine the speed at which this motor must run to develop 4 horsepower, would be to test it.

Therefore, if your generator runs at 1,500 revolutions per minute, the pulleys for driving will need to be in the ratio of 2 to 1. If the speed of the generator is some other amount the ratio can easily be calculated.

The flywheel on this motor is approximately 17 inches in diameter and 2.5 inches wide, therefore, the pulley on the generator should be about 8.5 inches in diameter and 2.5 inches wide.

The thickness of belt can be determined by the formula taken from Machinery's Handbook:

$$\text{Horsepower} = \frac{P\,W\,D\,N}{12{,}000}$$

P = number of plies in the belt; 1, 2 or 3.
W = width of belt in inches
D = diameter of smaller pulley in inches
N = revolutions per minute of the smaller pulley

The number of plies represented by P is just another name for the thickness. The width of belt D is limited to 2.5 inches, and had better be made 2 inches. D, the diameter of the smaller pulley, is 7.5 inches, and its speed per minute, N, is 1,500.

Solving the above formula for P, we have

$$P = \frac{12{,}000 \times 4}{2 \times 7.5 \times 1{,}500} = 2.15, \text{ which can be taken as 2,}$$

in other words a 2-ply belt should be used.

A governor may be obtained from the Pierce Speed Controller Co., Anderson, Ind., or the Duplex Engine-Governor Co., 80 Maiden Lane, New York City.

Both engine and generator should be solidly mounted. A large tank of water would be satisfactory for cooling, the thermo-syphon system being used. The outfit may be mounted on a steel or wood frame, or may be fastened to a stone, brick or concrete foundation.

Starter Gears Noisy

Editor THE AUTOMOBILE:—I have an electric starter on my car and several times lately when I put my foot on the button to start the car, it makes a noise as though every gear in the car was being stripped. Can you tell me the cause for this, and how to remedy same?

Lowville, N. Y. L. H. SMITH.

—It is possible that the gear teeth are worn or that the armature bearings allow play. Inspection should show whether this is so. It may be that the gears need oiling. It must not be forgotten that a starter should make a little noise, the amount depending on the design, workmanship and material.

Valve Diameters of Large Cars

Editor THE AUTOMOBILE:—What are the outside diameters of the valves in the following cars:

1—Pierce-Arrow 38-C3, 48-B3, and 66-A3; Packard 38 and 48; Peerless 38, 48 and 60; and Chalmers "Master" and "Light" sixes for 1915?

St. Louis, Mo. E. H. K.

—1—The outside diameters of the valves on these cars are as follows:

Pierce-Arrow,	38 C-3, 2 3/16 inches.
Pierce-Arrow,	48 B-3, 2⅜ inches.
Pierce-Arrow,	66 A-3, 2¾ inches.
Peerless,	38 Discontinued.
Peerless,	48 2 17/64 inches.
Peerless,	60 Discontinued.
Chalmers,	29 2.182 to 2.192 inches.
Chalmers,	29B 1.932 to 1.942 inches.

Make of Engine in Selden

Editor THE AUTOMOBILE:—What is the make of engine used by the Selden Motor Vehicle Co., in its five-passenger touring car, Model 40-T?

Alexandria, Louisiana. J. R. STANLEY.

—According to the information we have at hand the motor is either a Brownell, Continental or a Buffalo. We would advise you to write the Selden Motor Vehicle Co., Rochester, N. Y., stating the motor and car number, for more definite information.

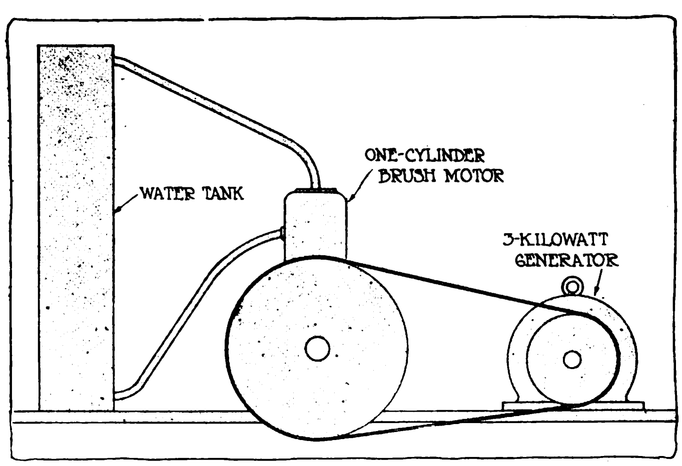

Fig. 3—Diagram showing layout for connecting Brush runabout motor to a 3 K.W. generator for stationary lighting work

The Engineering Digest

The Design of Valve Control Organs—Formulas Developed for Springs, Cams and Camshafts

A METHOD FOR DESIGNING CAMS IN UNISON WITH SPRING TENSIONS AND MOTOR SPEED

THE NEEDED RIGIDITY OF CAMSHAFTS

(*Continued from issue of September* 10)

FORMS and Dimensions of cams are determined by the folowing factors: (1) Valve lift, (2) nature of the tappet action—roller, flat or cambered plate or hammer type, (3) timing of opening and closing of valves; (4) the curve representing the piston travel, (5) the curve representing the valve travel under the kinematic influence of the valve spring, and (6) the play between tappet and valve stem.

The valve lift can be determined from equation 4 [see the previous instalment]. The nature of the tappet action (2) and the valve timing (3) must be chosen suitably. The form of the tappet head or roller determines the cam profile if the curve of valve travel is known. For the valve timing no definite rule can be established, as practice varies surprisingly. In 18 leading models of French automobile motors of 1912 the timing varies as follows (according to Henri Petit: Le Moteur, 1912 edition): The advance of exhaust valve opening from 30 degrees in Vinot-Déguingand and 32 degrees in Renault to 58 degrees in Ariès and Sultan; the retarding of exhaust valve closing from 0 degree in 9 of the 18 models to 15 degrees in the Peugeot; the retarding of the inlet valve opening from 0 degree in 4 models—including Panhard and Darracq—to 23.5 degrees in Renault; the retarding of the closing of the inlet valve from 5 degrees in Grégoire to 58 degrees in Peugeot, with the majority between 30 and 45 degrees.

These figures are all to be understood as relating to degrees upon the crankshaft circle.

In other works (Faroux: Construction Automobile, 1913 edition, and Lacoin: Construction et Réglage des Moteurs à Explosions, 5th edition) the average timing used by large French firms for an average motor speed of 1,370 revolutions per minute is given as 46, 5, 12 and 25 degrees for the four valve movements in question.

The large variations in the timing are no doubt partly due to undersized valves and too complicated forms of inlet and exhaust conduits, which interfere with the filling and emptying of cylinders within the regular periods of the cycle at high motor speeds and render it necessary to extend the periods for suction as well as those for exhaust by artificial means. The widely accepted opinion that the first and the fourth cylinders should have a different valve-timing from that of the second and the third must be explained likewise, as no other rational explanation presents itself. The only thing which can be stated in general, on the basis of practical experience, with regard to valve-timing, is that it must vary with the motor speed [meaning the normal motor speed], with the specific gas velocity in the conduits and with the volumetric compression. Theoretically next to nothing may be said, but for small high-speed motors practice sanctions the figures of 50, 4, 8 and 40 degrees for the advance of exhaust opening (α_1), the retarding of exhaust closing (β_1), the retarding of intake opening (α_2) and the retarding of intake closing (β_2), respectively.

In laying out separate cam diagrams it is important to determine the positions of both cams with accuracy. As the camshaft runs only half as fast as the crankshaft, the angles of advancing and retarding must be marked half as large on the cam diagram as the corresponding angles (α_1, β_1, α_2 and β_2) on the valve-timing diagram relating to the crankshaft. In accordance herewith the angle α_o spanned by the base of the exhaust cam and determining the period from opening to closing of the valve is

$$\alpha_o = 90° + \frac{\alpha_1 + \beta_1}{2} \qquad (8)$$

and for the intake valve

$$\beta_o = 90° - \frac{\alpha_2 - \beta_2}{2}, \qquad (9)$$

α_o and β_o being center angles of the camshaft circle. The lines dividing angles α_o and β_o in halves may be designated as cam axes; then the angle γ between the two cam axes is

$$\gamma = \tfrac{1}{2}\left(90° + \frac{\alpha_1 + \beta_1}{2} + 90° - \frac{\alpha_2 - \beta_2}{2}\right) + \frac{\alpha_2 - \beta_2}{2} = 90° + \frac{\alpha_1 + \beta_1 + \beta_2 - 2\beta_1 + 2\alpha_2 - \alpha_2}{4} = 90° + \frac{\alpha_1 + \alpha_2 - \beta_1 + \beta_2}{4} \qquad (10)$$

With these data a diagram is laid out, as in Fig. 3, on which the dead centers corresponding to two revolutions of the crankshaft—set 90 degrees apart, as a graphical expedient, to allow for the difference in crankshaft and camshaft movements—the cam axes and the four valve-opening and valve-closing points are marked on a circle. The diameter D of the circle is best taken as

$$D = 2\,(d' + 2m) \qquad (11)$$

as that gives a diagram on the scale of 2 to 1 or twice life size.

Notations

The angles α_1, β_1, α_2, β_2, α_o, β_o as explained in text.
d' = diameter of the base circle of the cams.
m = play between tappet and valve stem.
l = valve lift.
D = diameter of base circle of cams on 2 : 1 diagram.
D_1 = diameter of top circle of cams on 2 : 1 diagram.
d'' = diameter of roller.

With l the valve lift, the diameter of the top circle of the cams becomes

$$D = 2\,(d' + 2m + 2l) \qquad (12)$$

The base circle of the cams is to be chosen as large as the construction permits.

The above applies to the case when it is intended to use plate or hammer tappets. If rollers are to be used, D and D_1 must be enlarged with twice the diameter d'' of the roller, and then

$$D = 2\,(d' + d'' + 2m) \qquad (11A)$$

and

$$D_1 = 2\,(d' + d'' + 2m + 2l) \qquad (12A)$$

[It is noticed that the author is occupied only with standard construction and assumes, for example, that the valve lift of the intake valve should be the same as that of the exhaust valve, although much has been said lately of the advantage in making the lift of the intake valve greater rather than keeping the valve open for 40 degrees after dead center.—ED.]

When the diagram has been laid out up to this point, the piston travel curve is drawn into it for each cam, starting from the dead centers. If the gas velocity in the valve port were naturally constant, this curve would represent the valve travel, too. But in reality this is not the condition, and the piston travel curve represents only the minimum of the valve lift for each corresponding position of the piston. To prevent the gas velocity from assuming a higher value at any point of the piston travel than that provided for in the dimensions of the conduits, the lift of the valve at any point must be higher than shown by the curve of piston travel; compare the two pairs of curves in Fig. 3.

To construct the piston travel curve, the angles on the crankshaft circle corresponding to, for example, 10 equal divisions of the piston travel are first determined graphically, as in Fig. 2, the method being obvious. This figure is here shown on a reduced scale. The halves of these angles are transferred to the camshaft diagram, Fig. 3, so as to obtain a division of two 90 degree arcs of the cam circle in 10 unequal parts, corresponding to the 10 equal parts of the piston travel.

On the polar [radially converging] ordinates obtained in this manner, the corresponding lengths of l, enlarged to the 2 : 1 scale, are marked off, starting from circle D. These lengths can be figured from the equation

$$l = \frac{d^2 . s . n}{d_v . 6{,}000} \times \sin \alpha \ (1 \pm k \cos \alpha)$$

[this being a standard equation for a valve lift giving uniform gas velocity, approximately; compare "Hütte," 20th edition, volume II, page 307, or modern gasoline engine textbooks.—ED.]

Notations

d = cylinder bore in cm.
d_v = diameter of valve.
s = piston stroke in cm.
n = revolutions per minute of crankshaft.
α = center angle of crank.
k = crank length divided by connecting-rod length.
$Z = \sin \alpha \ (1 \pm k \cos \alpha)$.

The first member of the value for l, being a constant can be figured out readily. The second member, a variable in which α is the angle turned by the crank, at any given point in the movement, and k the ratio of crank length to connecting-rod length, may be designated as Z. The values for Z are calculated and tabulated herewith for a value of $k = 1/5$ and for 10 equal divisions of the piston stroke (compare Güldner: Entwerfen und Berechnen von Verbrennungsmotoren, 2nd edition, page 317).

termines the releasing-profile of the cam. Between the curve of the valve release and the parabola described by the valve under the influence of the valve spring [the vertical valve movement becoming a parabola when viewed in its relation to the rotating circumference of a cam or camshaft.—ED.], there must be a certain relation, in order to avoid noisy bounding of the tappet on the cam or of the valve stem on the tappet, accompanied by too late closing of the valve.

The release-curve must therefore coincide with one representing the free (spring-determined) movement of the valve during the closing period. A relation between the trajectory and the velocities of the movement must therefore be provided. Fig. 1 indicates the method to be followed [and illustrates also the manner of obtaining equa-

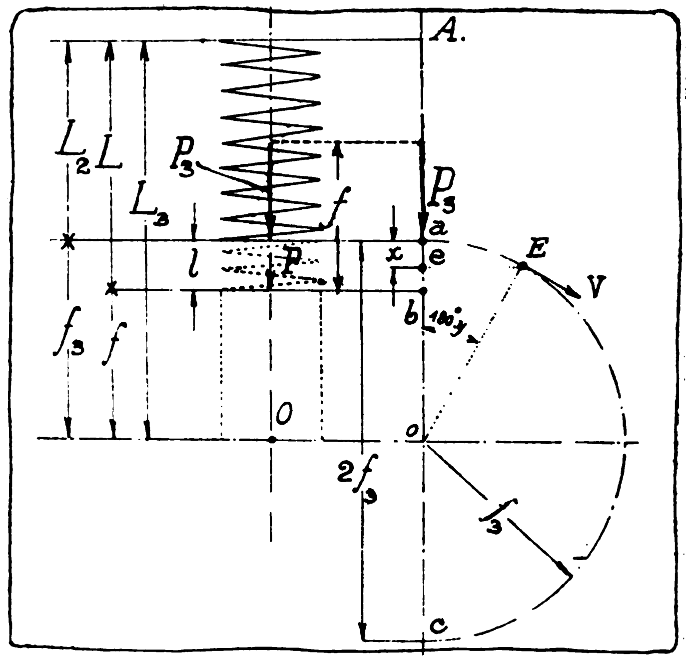

Fig. 1—Diagram of spring tensions, auxiliary in determining valve-releasing curve

tions 5, 6 and 7, relating to the dimensions of valve springs, in the previous instalment], the movement in question being conceived as part of a rectilinear oscillation of which the full course ac is equal to twice the deflection of the valve spring at fully open valve, so that $ac = 2f_3$.

It is assumed, as may be done without notable error, that the spring tensions are proportionate to the deflections. Aa represents the length of the spring at its initial tension; that is, with valve fully open, as at the beginning of the closing; and Ao the total length of the released spring (equal to L_2 by previous notation), so that the force of the spring steadily diminishes from a to o, dropping from P_3 at a to zero at o. Also, we have $P_3 : f_3 = P : f$.

Under such conditions the oscillation can be considered as the projection—speaking with reference to the graphic

Percentage of Piston Stroke	10	20	30	40	50	60	70	80	90	100
Values of Z	0.648	0.853	0.962	1.011	1.014	0.976	0.892	0.759	0.554	0

The values for l_1, l_2, l_3, etc., are now in the form of $l = AZ$, in which

$$A = \frac{d^2 . s . n}{d_v . 6{,}000} \qquad (13)$$

and the values for Z are taken from the table above.

The curve of the valve travel and of the corresponding time periods during the closing movement of the valve de-

representation of it—of a uniform circular movement which the valve body describes under the influence of a radial force P_3 and a constant tangential velocity V.

If the mass of the valve body is M and t_o is the period of oscillation; that is, the time in which the body, moving at uniform velocity along the circle, reaches from a to c, then

$$t_0 = \pi \sqrt{\frac{M \cdot f_1}{P_1}}$$

If we consider an arbitrarily chosen point e between a and b, which is the projection of point E on the circle, and if we designate the length of ae as x and the angle aoE as $180° \cdot y$, then the time in which the body covers the distance ae, or the arc aE of the circle, is $t = t_0 \cdot y$, or, inserting the value of t_0,

$$t = y \cdot \pi \sqrt{\frac{M \cdot f_1}{P_1}}$$

Consequently $$y = \frac{t}{\pi} \sqrt{\frac{P_1}{M \cdot f_1}} \qquad (14)$$

On the other hand we have the relation (see Fig. 1)

$$x = f_1 \left[1 - \cos\left(y \cdot 180°\right)\right]$$

By insertion of the value for y from equation 14, this gives

$$x = f_1 \left(1 - \cos\right) \frac{180°}{\pi} \cdot t \sqrt{\frac{P_1}{M \cdot f_1}} \qquad (15)$$

By substituting for M its approximate equivalent .1Q, [under the metric system which has 9.81 m/sec for the factor of acceleration], where Q is the weight of the valve body, including spring plate and spline, we obtain (for f_1 expressed in cm)

$$x = f_1 \left[1 - \cos\left(57.29578° \times 31.623 \sqrt{\frac{P_1}{f_1 \cdot Q}} \cdot t\right)\right] \qquad (16)$$

By designating as C the constant in the expression for the angle $y \cdot 180°$, we have first

$$C = 1811.1 \times \sqrt{\frac{P_1}{f_1 \cdot Q}} \qquad (17)$$

and, by making use of this designation, equation 16 takes the simpler form

$$x = f_1 \left[1 - \cos\left(C \cdot t\right)°\right] \qquad (18)$$

In order to draw this curve [meaning the curve determined by the values of x for a suitable number of locations of e] into the diagram, Fig. 3, it is necessary to determine the point at which closing begins, for both cams. With a view to the silence of the motor it would be desirable to place this point as close to the axis of the cam as possible and to shape the release curve gently declining. The piston travel curve admits however in only slight degree of such design, and the beginning of the closing period must usually lie 30 to 35 degrees from the point of valve closure, if the risk shall be avoided of raising the gas velocity toward the end of the exhaust stroke, thereby causing imperfect scavenging and poor subsequent filling of cylinders.

The values for x must be laid out radially from the top curve D_1 toward the center, while the corresponding values for t are represented by a radial division of the circle. This division is regulated by the following considerations:

If n is the number of crankshaft revolutions per minute, the camshaft makes $n : 120$ turns per second. Accordingly, the time in which the camshaft turns 2 degrees can be expressed as

$$T = \frac{2}{3n} \text{second,} \qquad (19)$$

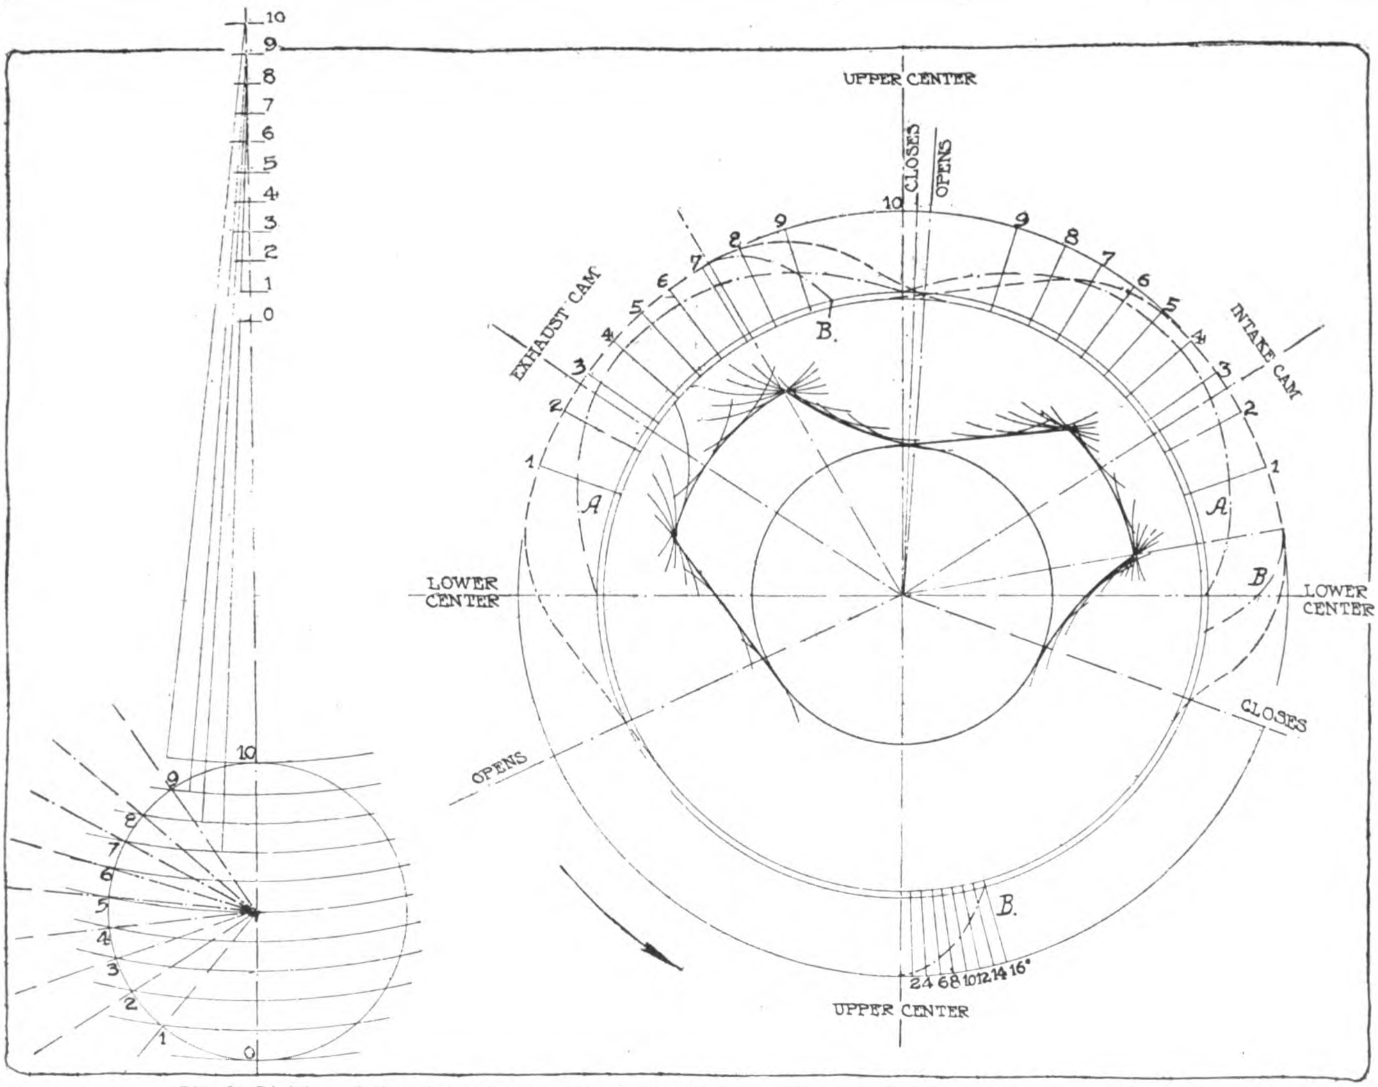

Fig. 2—Division of the piston travel. Fig. 3—Graphic determination of location and shapes of cams

and if arcs of 2 degrees are chosen for abscissas in the system of polar co-ordinates, the values for t obtained are

$$t_0 = 0;\ t_1 = \frac{2}{3n};\ t_2 = \frac{4}{3n};\ t_3 = \frac{6}{3n};\ \text{etc.}$$

The corresponding values for x can then be calculated from equation 18.

Compromise in the Shapes

After the curve for each cam has been determined and laid out in the manner explained, the curve of the real valve travel can be found. The main condition for realizing a correct and practicable design is here that this curve lies outside of the curves so far determined, in each case. With the use of plate or hammer tappets it is necessary to make the raising and the releasing camside profiles symmetrical, as they must develop themselves tangentially upon the plate surface at the lifting as well as at the seating of the valve and therefore must be made rather strongly convex, tangentially to the base circle of the cam. If the camside is made rectilinear and tangential to the base circle and the tappet plate is flat, a blow is delivered against the plate at every lifting of the valve, and this is not admissible in view of the requirements for silence and durability. On the other hand, the curve of the camside must not be too convex, as then it collides with the curve of the piston travel. In most cases it is preferable to form the camside tangential to its base circle and convex at the junction with the piston travel curve, while giving the curvature at the cam base a smaller radius than at the cam top. Even with symmetrical shaping of the camsides the cams become rather pointed if the lines are made notably convex, and it is therefore in most cases not practicable to shape the releasing-profile with further special reference to an easy and slow closing of the valve. This is especially true for intake valves, as they span a smaller angle than the exhaust valves.

The inner end of the curve [by which the play in the tappet elements is taken up] is joined, between the circles D and d_1, as flatly tangential to the latter as possible.

If rollers are to be used or hammer tappets with heads of semi-circular profile, it is advantageous to shape the lifting camside rectilinear or even concave, in order to cause rapid opening of the valve, while the releasing-curve should be formed so as to retard the valve movement at the closing. The most approved method is to draw the lifting-curve as a rectilinear tangent to a circle of the diameter $D - 2m$ and to make it join the top circle D_1 with a rounding of radius $.5d''$ [d'' being the diameter of the roller, as before], while the releasing-profile is made as strongly concave as circumstances permit and, at the beginning of the valve-closing period, is joined tangentially to the kinematic valve-closing curve [being that marked B in Fig. 3 and determined by the valve spring tension] and continued concavely to the circle of diameter $D - 2m$.

The curve so obtained represents the movement of the center of the tappet roller and thus of the valve itself. To obtain the actual shape of the cam, arcs are described from points in this curve, as centers, with a radius of $.5d''$, and the cam shape is then drawn as the curve following these arcs tangentially, as indicated in Fig. 3.

For this illustration a motor with 80 millimeter bore and 120 millimeter stroke was chosen. The piston travel curves are marked A and the kinematic releasing-curves of the valves are marked B. To avoid confusion, B is constructed separately at the bottom part of the drawing and is afterwards transferred to its right places. The diagram is drawn to 2 : 1 scale [slightly changed in the reproduction] and intended for tappets with rollers. The curves for the travel of the roller centers are drawn in dashes, the final cam shape in full lines and the auxiliary curves, both A and B, in dots and dashes.

The lifting-curve of the intake cam intersects the piston travel curve at the beginning of the suction stroke in Fig. 3, and this relation would indicate increased gas velocity at this point. It is the unavoidable consequence of the retarding of the intake valve opening; but, far from being a drawback, the increased gas velocity at the beginning of the suction is greatly desired with a view to obtaining a uniform vaporization. The volumetric efficiency of the motor does not suffer; if for no other reason then because any loss of charge at the beginning of the suction is more than offset by a considerable retarding of the valve closure.

Required Rigidity of Camshaft

In motors with cylinders close together and short crankshafts running in only two bearings, the camshaft can also be mounted in two bearings, but must then be of very liberal diameter to avoid deflections and vibrations. An ordinary calculation of strength is insufficient, and it is necessary to ascertain the maximum deflection to which the shaft can be subjected. Even for shafts running in three bearings this calculation of the deflection is urgently advised.

The force to be considered is the resistance of the exhaust valve against lifting, and this is composed of the pressure of the expanding gases against the valve and the spring tension P.

Notations

v = the gas volume at end of working stroke = cylinder volume.
v_0 = gas volume at beginning of working stroke = volume of compression chamber.
v' = gas volume at moment of opening of exhaust valve.
p_0 = pressure at moment of explosion.
p_1 = pressure at moment of opening of exhaust valve.
p_2 = pressure at beginning of working stroke.

We have, through the relations of pressures to volumes,

$$p_1 = \frac{p_2 \cdot v_0}{v'}$$

For an advance release of 50 degrees the value for v' can be taken as approximately $v' = 0.85\,v$, considering the proportions between angle of turn and piston travel, and therefore

$$p_1 = p_2 \frac{v_0}{v} \times 1.175$$

As referred to before, e being the volumetric factor of compression,

$$\frac{v_0}{v} = \frac{1}{e} \quad \text{and hence} \quad p_1 = p_2 \frac{1}{e} \times 1.175 \qquad (20)$$

In practice this value for p_1 must be multiplied with the thermic efficiency co-efficient 0.75; which gives

$$p_1 = p_2 \frac{1}{e} \times 0.88 \qquad (21)$$

According to earlier research [referring to a development by the same author of a power formula for automobile motors without the aid of an assumed value for the mean effective piston pressure, published in *Der Motorwagen* for May 10, 1914]

$$p_2 = e^{\kappa} + \frac{H\,(e-1)}{T_0\,Cvm\,(L+1)}$$

where κ (kappa) is the ratio between the specific heats of the explosive mixture at unvarying pressure and at unvarying volume, H the heat units of 1 kg. of gasoline, T_0 the absolute temperature at the beginning of the compression stroke, Cvm the mean specific heat of the gas mixture at constant volume and L the weight of the air required for the combustion of 1 kg. of gasoline.

From this equation, by insertion of the assumed values, there is obtained:

$$p_2 = e^{1.3} + 7\,(e - 1),$$

and thus we get from equation 21:

$$p_1 = \left(e^{0.3} + 7\,\frac{e-1}{e}\right) \times 0.88 = 0.88 \times e^{0.3} + 6.2\,\frac{e-1}{e} \quad (22)$$

[The author's reference to a formula developed on a previous occasion is here reproduced literally, but it seems necessary to state that an examination of this reference discloses several discrepancies between the notations used there and those employed in the present text, to the effect that only a lengthy and searching analysis could determine whether, despite these discrepancies, the author is justified in inserting the value for p_2, as taken from his development of a power formula, in equation 21 of the present text. If he is not so justified, the whole subsequent development of numerical values for the pressures acting to deflect a camshaft is of course vitiated, but is presented here on account of the interest of his method, while those sufficiently interested in ascertaining the true formula for p_1—to take the place of equation 22 which is in doubt—may look up the original articles or develop a formula for p_1 by independent means.

At any rate, the table of values given below should be accepted only with reservation.—Ed.]

The discrepancies referred to are the following (with allowance for certain changes from both originals made for typographical reasons):

Notations employed	*In present text*	*In the reference*
Gas volume equal to cylinder volume =	v	v_0
Gas volume equal to compression space =	v_0	v'
Gas volume at opening of exhaust valve =	v'	not used
Pressure at moment of explosion =	p_0	p_2
Pressure at opening of exhaust valve =	p_1	not used
Pressure just before explosion-compression =	p_2	p_1
Pressure at beginning of compression stroke =	not used	$p_0 = 1$

The following table gives the values for p_1 calculated from equation 22 in kilograms per square centimeter for 50 degrees advance release of the exhaust and for compressions ranging from $e = 4$ to $e = 5$.

$e =$	4	4.1	4.2	4.3	4.4	4.5	4.6	4.7	4.8	4.9	5
Pressure p_1 at moment of opening of exhaust valve	5.98	6.02	6.08	6.12	6.16	6.20	6.24	6.28	6.32	6.35	6.39

To obtain p_1 for another advance of the exhaust, the value given in the table may be multiplied with $0.85 : x$, in which x stands for $v' : v$ for the desired advance.

The force K necessary for raising the exhaust valve is accordingly, d_2 being the diameter of the valve:

$$K = P + \frac{\pi d^2_2}{4} \cdot p_1 \quad (23)$$

The importance of this calculation should not be underrated, as K can take considerable values. For example, even for a small bore of 80 mm, the value of K is found to be 87.8 kg.; and this value grows at the square of the bore.

The camshaft should have a diameter giving so high a resistance that the maximum deflection at the locations of the cams does not exceed 0.02 cm.

In Fig. 4, let a and b be the distances of the exhaust cam axis to the center lines of the bearings A and B and δ (delta) the diameter of the shaft.

We have then (see handbooks on beam stresses):

$$f = \frac{64\,K}{2\pi\,\delta^4 . E} \cdot \frac{a^2 . b^2}{a + b}$$

and, for $f = 0.02$ cm and $E = 2{,}200{,}000$ kg.:

$$\delta = 0.111 \sqrt[4]{\frac{K . a^2 b^2}{a + b}} \quad (24)$$

—From article by A. G. von Loewe in *Der Motorwagen*, July 10.

Construction Lessons from Grand Prize and Tourist Trophy Races

ONCE let loose, so to speak, upon a stem to stern design for racing and racing alone, almost every engineer turned to the overhead valve engine quite naturally, says *Automobile Engineer* editorially in commenting upon the inferences which engineers and the employers of engineers are now in a position to draw from the results of the English Tourist Trophy race and the French Grand Prize race of this year. Some of the remarks of the commentator have a bearing upon normal as well as racing construction and are reproduced in substance—with some additional comment—as follows:

The premier race of the year has been won by a type of engine quite new to the road, and the Minervas in the Tourist Trophy event have shown that the theoretical virtues of a hemispherical combustion chamber may be exploited by other means than the use of multiple poppet valves. The Mercedes and the Minervas were of equal originality of design, though in both of them the same theories were applied which underlie the Peugeot construction.

Did the Better Cooling Win?

There is no doubt that the Mercedes had more power than the Peugeots. In both types the top gear was direct, and that of the Mercedes was a good deal the lower. This means that the Mercedes drivers were not afraid of driving their engines at a decidedly higher speed than that at which the Peugeots were turning. Hence it is easy to see where the higher power came from. This leads to the all-important question: Why could the Mercedes engines stand the higher speed?

[In the absence of any evidence of overheating of Peugeot motors, the urgency of this question is perhaps not so conclusive as it might seem at first glance. It is possible that it was inferior road qualities of the Peugeot cars which prevented the vehicle speed, and therefore the motor speed, from being pushed to the limit, and that the reasons for the slight superiority of the Mercedes cars should be sought in

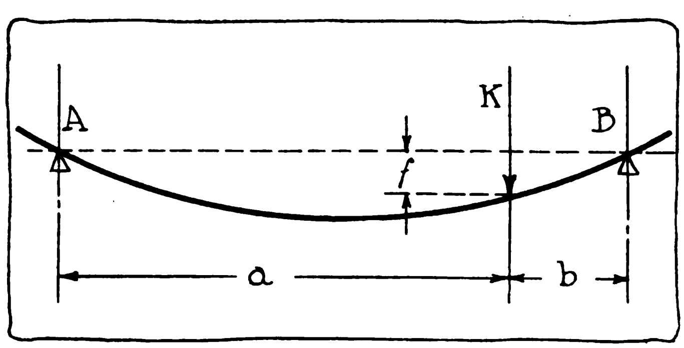

Fig. 4—Diagram of elements in rigidity of camshafts

their general vehicle design and in their spring suspensions, which determine how fast the driver dares to go—more directly than any anticipated motor troubles.—Ed.]

It is the experience of most engineers that engines which can be run at four thousand revolutions per minute for an hour cannot be kept turning at that speed for five or six hours, although they may be able to run at three thousand revolutions for an almost indefinite period. On the face of it, there seems some difficulty in explaining this, because it is not clear what happens when running fast that takes an hour or more to develop. Fatigue of the materials is sometimes the reason; but what is wanted is an explanation as to why an hour at four thousand revolutions, say, should be more likely to produce fatigue than a week at three thousand. In not a few cases failures in engines which are being run at their maximum are traceable to overheating of one part or another—local overheating in fact—and this despite the utmost precautions to prevent the temperature of the water from rising unduly. It may be that in a highly stressed water-cooled engine heat is accumulated slightly faster than it can be dissipated, and that it is this slow accumulation which eventually takes effect—sooner or later, according to the design details of the engine.

Now recall the fact that the Mercedes steel cylinders are machined all over, inside and outside, that the jackets are welded on afterwards, so that the water spaces are all alike and there is an equally free flow of water around each combustion head and valve seat. Add to this that the walls are thinner than they must be if of cast-iron, and it becomes obvious that the cooling of the Mercedes engine is more certain, and probably more efficient as well, than the cooling of any cast-iron block-cylindered motor ever could be.

The Oil—Another Cumulative Factor

[In seeking for a factor which undergoes certain changes by the mere lapse of time, apparently, it would perhaps be well to consider the lubricating oil. In aviation motors of the Mercedes type and in nearly all racing motors a portion of the oil used is returned to the oil circulation system and is used over again. Now it is known that oil when exposed for some length of time to heat undergoes certain chemical changes of a rather subtle nature and largely depending upon exact temperatures and time periods. The polymerization of turpentine into isoprene and of isoprene into synthetic rubber is perhaps the best known example of this action. The oils are "cracked" more or less and lose volatile elements whose vaporization in the motor cylinders naturally contributes to the cooling properties of the oil so long as it is fresh. It is thus conceivable that after some length of time at maximum temperature of the motor that portion of the lubricant which is derived from the circulation system loses both in lubricating and in cooling qualities, eventually lowering the efficiency of the motor for continued running—unless an entirely new oil supply is provided.—Ed.]

Bevel Gear and Single Camshaft

As to the operation of poppet valves—with the now almost universal four-valve design, so far as racing motors are concerned—the Mercedes success has shown beyond all possible doubt that there is no need for the Peugeot train of spurgears to drive an overhead camshaft. On the contrary, it shows that a properly proportioned bevel gear of much smaller weight is just as efficient.

It has been said that in a high-stressed engine valve rockers are a source of weakness; this opinion accounting for the direct operation of the valves by Peugeot and Sunbeam from a pair of camshafts. As the single camshaft is constructively much preferable, it is good to know that the bevel-gear construction need not be feared any longer.

Another point brought out by the Mercedes is that plain bearings are good enough for a racing crankshaft if the oil pressure is high enough. Undoubtedly the rigidity of a good plain bearing gives much better resistance to the bending stresses of a shaft than ball bearings, though but few cases of actual failure of the latter have been reported.

A Question of Bearings

[At this point continental technical opinion leans toward the idea that plain bearings for crankshafts will eventually be worn out conically from the effects of irresistible vibrations, unless the dimensions are made larger than admissible from other points of view, and that, on the other hand, ball bearings can be protected against vibrations if they are either mounted so as to permit them to oscillate in response to the shaft vibrations or so designed that the balls can oscillate in the fixed outer ball race. This view thus favors ball bearings in the matter of durability and for ordinary cars—their adaptedness for block cast motors and short crankshafts being also considered—while for a racing motor the plain bearings may offer superior guarantees for any single exploitation of its stamina.—Ed.]

Cantilever Springs in the Balance

It is to be regretted that the Vauxhall and the Aquila-Italiana in the two races were never able to show the behavior of their cantilever rear suspensions. If this type of spring is satisfactory for the ultimate test of the road race, it should be better than the half-elliptic, because it is easy to adapt to give a large amplitude of spring movement, and it has several advantages from the points of view of the erecting shop and the body builder. It must be left for next year to show how it can behave when called upon.

The outstanding lesson of the two big races is really that there is still plenty of opportunity for originality of design; that those who had the courage to follow their own ideas without any reference to others have reaped a rich reward. —From *Automobile Engineer*, August 15.

Legal Views on Contributory Negligence

A motor car was started from front of plaintiff's residence on a street at right angles with the trolley line, which was about 40 feet away. The trolley had head-lights and other lights and was easily seen at a distance of 700 feet. The chauffeur wished to turn right on the car street. As he turned a collision occurred. It came out on the trial that the car was going 20 miles per hour and the automobile 4 to 5 miles per hour. The Court said that as the chauffeur saw the car when he was about to enter the track and continued for 25 feet when he might have stopped or turned off, or speeded up and gone straight across, he was guilty of contributory negligence because he did neither of these things but went leisurely on his way.—*Bertrand vs. Milwaukee Electric Railway & Light Co.*, 146 *N. W.* (*Wis.*), 915.

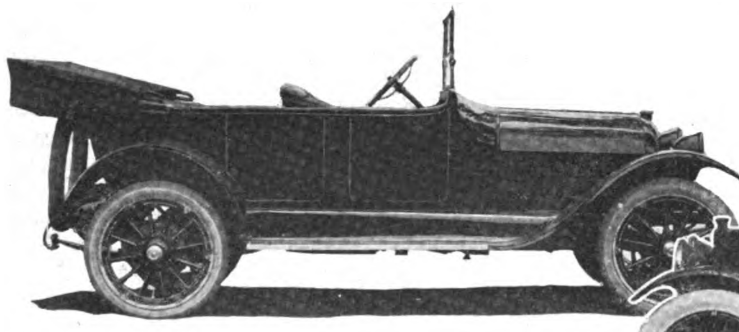
Speeding Across Railroad Tracks

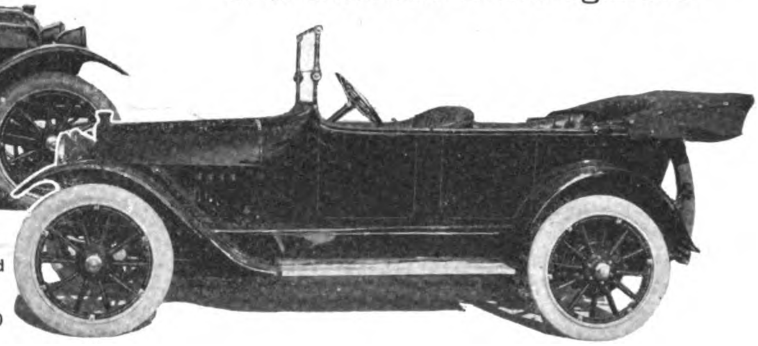
The fact that a motorist kept on driving his machine at a high speed when he came to a railroad crossing was held by the Court in a recent case to be such negligence on his part as to prevent him from being successful when he sued for injuries for damages caused by a collision with the rear end of a freight train.

A motorist was driving at a high speed along a country road. On approaching a railroad crossing he did not slow down and collided with the rear end of a freight train which was on the roadway. The Court held that even if no warning gong was rung, he was not relieved from ordinary precaution for his own safety, but as he had his side curtains down and his windshield up it must be presumed that he knew he had only his sight and his knowledge of the location to depend on, and for that reason the railroad company was held free from liability.—*Farmer vs. N. Y., N. H. & H. R. R. Co.*, 104 *N. E.* 492.

New Velie Six $1,595—Two Other Models

New Model Has Spiral Bevel Axle —Tapered Frame—Vacuum Feed and Atwater Kent Ignition





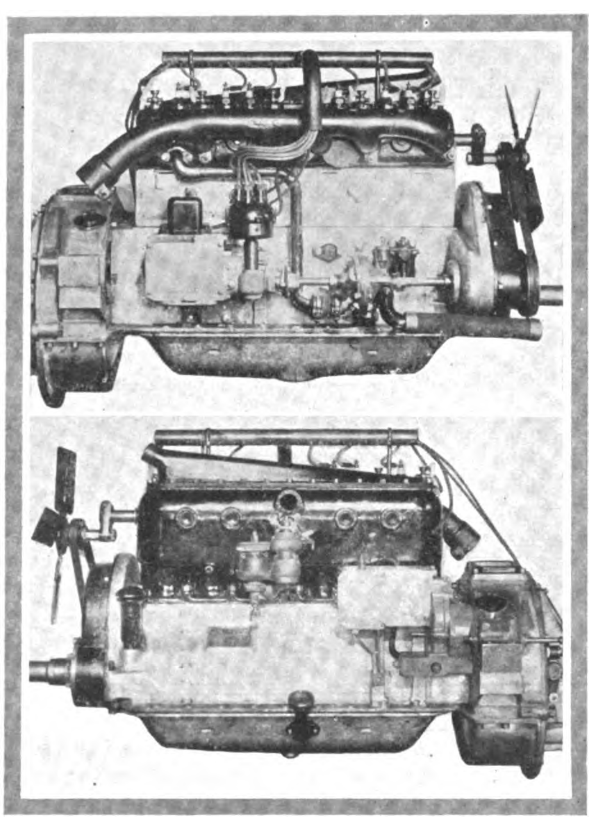
Left—New Biltwel Velie with round nosed radiator and smooth body lines

Right—Four-cylinder Velie model 12 which sells for $1,750

AN entirely new small six selling at $1,595 and called the Biltwel series 15 is the feature of the line of the Velie Motor Vehicle Co., Moline, Ill., for the ensuing season. Last season's small four, the model 11 has been discontinued and the big six, called series 14, this year and the big four called series 12, have been improved and reduced in price. The four has been reduced, from $2,000 to $1,750, and the six from $2,350 to $2,015. New bodies are featured on all the cars. In the new six the Velie company has incorporated a number of special features which have lately come into use by motor car builders. The spiral bevel rear axle gears is one of these features, the tapered frame, another, and it might be mentioned that the frame of the new Velie brings the distance between front spring centers to 27 1-4 inches. The rear of the frame is 37 inches wide and the front 29 1-4. Hotchkiss drive is another adoption. In this car propulsion is through the springs, eliminating the conventional radius rods or torsion tube. Stewart vacuum fuel feed and Atwater Kent ignition with automatic spark advance are other features used in the new small six which were not used on previous models.

The engine is a Continental, forming a three-point suspended unit power plant with a cone clutch and gearset made by the Warner Gear Co., Toledo, O. The engine cylinders are cast in block, have a bore and stroke of 3 1-2 by 5 inches and are of L-head design. The crankshaft is supported by three bearings and through helical gears operates the camshaft. The valves controlled by the shaft are 1 1-2 inches in diameter. The oiling system is a combination of circulating splash and pressure, the main bearings being fed directly by leads and the reciprocating parts by splash distribution.

On the left side of the engine is a Stromberg model H.B. 2 carbureter of 1 1-4 inch. This carbureter bolts directly to the cylinders feeding to the valves through a cored passage in the casting. The carbureter air intake is connected to the exhaust manifold by a sleeve and pipe. Fuel feed is by the Stewart vacuum system in which a small tank is placed behind the dash while the regular fuel tank is in the rear of the chassis. The fuel is drawn into the small tank by motor suction and then fed to the carbureter by gravity, doing away with all pumps and air lines necessary with a direct pressure feed.



Upper—Right side of Continental motor used in new Velie Biltwel six. The pump, Atwater Kent ignition system and generator are on this side

Lower—Left side of motor showing high mounting of the carbureter and position of starting motor. The construction of the fan bracket is clearly shown and the oil gauge is seen at the bottom of the crankcase

High-Speed Cranker

On the same side with the carbureter is a Gray & Davis small, high-speed engine cranker operating at 6 volts and turning over the engine through the medium of a toothed-flywheel. On the left side there is also an oil gauge attached to the lower portion of the crankcase.

On the right or exhaust side of the motor is the small-type Gray & Davis 6-volt lighting generator with the regulator installed on top of its casing. Next to the generator is the Atwater Kent distributor with wires leading from it into a conduit making a neat wiring installation.

The ignition system is fitted with a reverse-current switch. This switch is of the rotary type with four positions instead of two.

The electric system has all its wires housed in metal conduits and the headlight wiring is concealed. The headlights are supported by single props which house the wires. These headlights are of the double-type affording a means of using bright or diffused light. Every lighting circuit is fused, and there is a combination switch installed which allows of any set of lamps being used. The tail light and dash light are wired in series, so if the dash light goes out the tail light is extinguished also.

The clutch is of the cone type with a 2 1-2-inch face with an angle of 12 1-2 degrees. Back of the clutch is a four-speed selective gearset, with the following motor-to-wheel ratios: First, 12.87 to 1, second, 6.73 to 1, third, which is direct, 4.08 to 1 and geared up fourth, 3.42 to 1. This gearbox is of the narrow type in which the countershaft is above the shifter shaft making a neat installation and taking up little room apparently.

The drive from the gearset is through an open shaft fitted with two Spicer universals to a Timken floating rear axle fitted with spiral-bevel gears. This type with its sliding action of the teeth offers a set more quiet than the straight bevel and may be called the mean between the worm and the ordinary bevel. The car's wheelbase is 124 inches.

The controls of the new Velie six have interesting points of advantage. The steering post for example, placed on the left side, has self-lubricating bushings. This post is of Gemmer make and has a large horn button at its center. To the right of it is the ball-joint gearshift lever. The ignition control has an auxiliary in the form of dry cells operated by a switch near the floor boards and within easy reach of the driver's right hand.

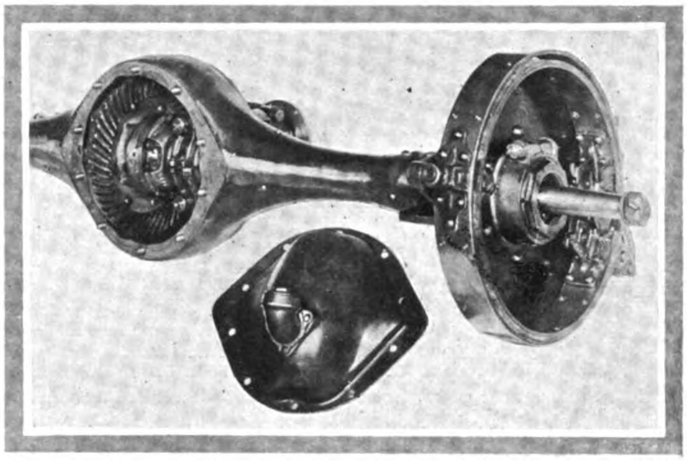
The new Velie frame has an unusual taper. The frame is 4 1-2 inches deep by 2 by 5-32 inch and because of its narrowness in front, only 27 1-4 inches between spring centers, the car has a very short turning radius.

On the improved six no chassis changes have been made, but the body has been altered, the lines are better, and the cowl dash arrangement is slightly different. The rear tires now are of the non-skid type instead of plain tread and a Taylor Noil pump is given as added equipment. The only other change has been in the fitting of headlights with dimmers.

Continental Motor Used

The engine in the big six is a Continental of 3 3-4 by 5 1-4 inches bore and stroke and has its cylinders cast in blocks of three. The engine shows nothing radical but differs from the small six motor in that it is equipped with a Bosch magneto instead of an Atwater Kent system and the Gray & Davis electric cranking and lighting system is of the larger type.

The engine drives to a disk clutch and four-speed gearset and then to a floating rear axle. By propeller shaft fitted with two Spicer universal joints. The wheelbase is 126 inches.



New Biltwel rear axle grease filler on axle cover

The price of the Velie big six has been reduced from $2,350 to $2,015 for the five-passenger. This and the seven are the only open types made. A sedan is listed at $2,715. Blue with Velie green optional are the touring colors while the sedan is sold only in blue.

The carried-over Velie four, shows the same general body lines as the other cars and the changes in this are the same as those made in the big six with one additional. This has been the increase in tire size from 36 by 4 to 37 by 5 1-2.

This car is the only one using a motor made in the Velie shops. It is of L-head design with pair-cast cylinders of 4 5-8 by 5 1-4 inches bore and stroke. A feature of this engine is the transverse magneto driven by worm gears, and set over the timing gear case. Another unusual feature is that the carbureter is on the right side with its intake pipe passing over the cylinders to the manifold on the left side. This forms a very accessible position for the Stromberg carbureter.

The running gear of the four consists of a disk clutch, four-speed gearset giving a motor to wheel ratio on third or high of 3 13-14 to 1. The rear axle is a Timken floating type and the wheelbase 121 inches.

The Velie four has been reduced in price as mentioned previously from $2,000, in four- and five-passenger form, to $1,750. A five- passenger sedan is sold at $2,450. The latter is finished in blue only while the touring cars are painted in either blue or Velie green.

Two Bosch Magnetos—One Has New Distributer

New Model With Collector Ring-Distributer for Small Cars—Other Model Gives Easy Starting, Called Vibrating Duplex System

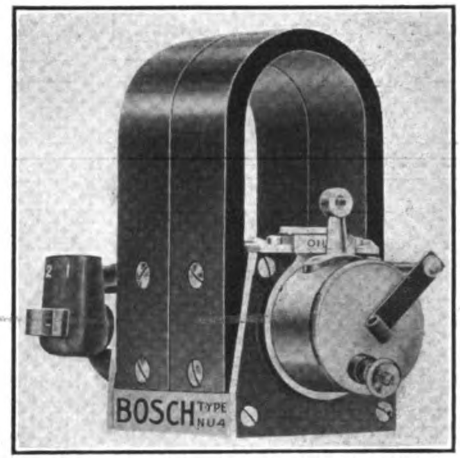

Fig. 1—New NU4 without distributer. The breaker box construction is conventional. A double slip ring takes the place of the distributer

TWO entirely new Bosch systems to meet the requirements of recent developments in automobile design have just been announced. They are a vibrating duplex system to make possible the certain starting of the motor when cranked at low speeds by the starter, and an entirely new design of high-tension magneto, Fig. 1, with a combined current collector ring and distributer to take care of the popular-priced, small four-cylinder car.

Simplified Magneto for Small Fours

With the placing on the market of several makes of small four-cylinder cars of light weight, the Bosch company has kept its product up to time by the marketing of a greatly simplified high-tension magneto especially designed for this work. By the elimination of the distributer as an independent unit of the magneto construction it has become possible to reduce materially the number of parts used in the manufacture of the magneto, making it exceedingly light.

The function of distributing the ignition current has been placed in the new instrument on the slip ring. The single slip ring however, has been replaced and instead a double ring has been substituted which not only acts as the collector for the high-tension current but as the distributer as well.

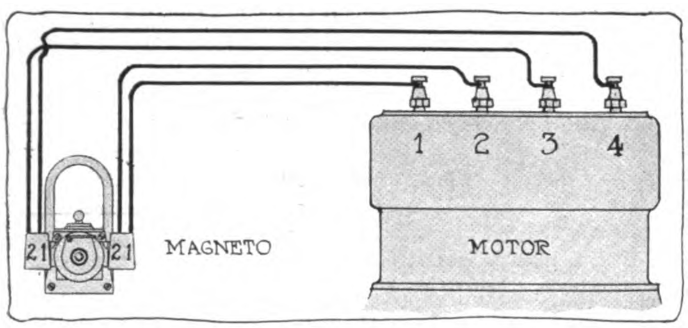

Fig. 2—Simple wiring diagram of new NU4 magneto without distributer

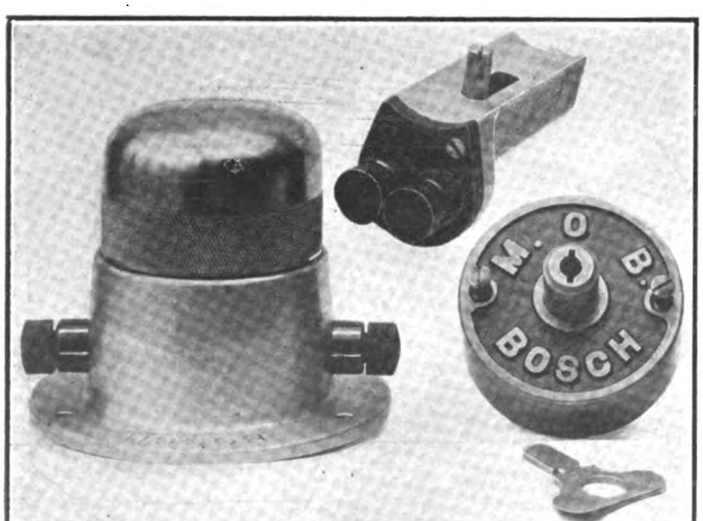

Fig 3—Components of vibrating duplex system. The inclosed vibrating coil is at the left and the dash switch at the right

Another new feature about the new Bosch magneto, which will bear the name NU4, is the use of two entirely separate armature windings. Hitherto the secondary winding in the Bosch magneto has been practically a continuation of the primary, its inner end connecting with the latter and the other end is led to the insulated slip ring or current connector ring which rotates solidly with the armature shaft of the instrument. From the slip ring the high-tension current is collected by a brush and led to a central point on the distributer block. It is taken from this point to the various plug points by a rotating brush.

New System on NU4

On the NU4, Fig. 2, an entirely different system has been worked out. The primary winding, as in other types, has one end connected to the armature core and the other end to the insulated contact block supporting the long platinum screw on the contact breaker. The breaker box mechanism is in every particular similar to that used on previous Bosch models. It is shown in Fig. 4.

It is in the high-tension winding that the first difference manifests itself. In the new model there is no connection whatever between the primary and secondary windings. In fact they are heavily insulated from each other. The two ends of the secondary winding are connected to two metal segments located on a double slip ring as shown in Fig. 7. This double slip ring is mounted on the armature shaft and rotates with it.

Bearing against the double slip ring are two pairs of brushes. Each of these four brushes forms the terminal of a spark plug wire. As the armature rotates the segments form a contact in turn with each of the four brushes sending the spark to the plug to which contact is made. The high-tension current is thus distributed without recourse to the ordinary type of distributer.

The keynote of the new magneto is the slip ring which so ingeniously takes care of the needs of the collecting and distribution functions of the magneto. It is made in one piece with two deep grooves in place of the single groove seen on other Bosch rings. It is of hard rubber insulating material. Imbedded in each groove is a metal segment. The two segments are set diametrically opposite on the armature shaft, that is, a distance of 180 degrees in angular measure. They are insulated from each other as well as from the core of the armature and the magneto frame.

The four brushes are supported by two double brush holders, as is clearly illustrated in Fig. 7. With this arrangement the magneto will give two sparks to each revolution from alternate segments on the collector-distributor ring. The brush holders fit into openings provided in each side of the driving shaft end plate and are held in place by catch springs. The brush holders together with the brushes can be pulled out of place without tools.

The NU4 magneto is installed so that it is driven at engine speed. As there will be a surplus spark in each cylinder 360 degrees behind the effective spark or one revolution of the crankshaft, the timing must be such that the inlet valve has not started to open at this time and so that the exhaust is preferably still open. Under average conditions this state of affairs is secured if the magneto is fitted so that the interrupter housing is in full retard position just as the interrupter screws are about to separate when the number 1 cylinder is on top center. At this time the metal segments of the slip ring should be in contact with the brush marked 1.

This magneto is suitable for installations up to 30 horsepower. It can be used as the sole source of ignition on engines up to this size, being of independent design. It can, however, be used to advantage in connection with the Bosch Duplex above described.

Vibrating System Instead of Dual

The vibrating system is designed to render unnecessary a dual ignition system on cars that are cranked by a starting motor at such a low speed that the ignition current from the ordinary magneto is insufficient to give certain ignition. Instead of using independent current supplied by a set of dry batteries or by some other source, the new Bosch system takes the primary current from the primary winding of the magneto and by means of an inclosed type of coil and a battery placed in series with the primary winding produces the high-tension spark necessary at the plug gaps.

The number of extra parts required with this new system is small. No additional wires running to the magneto are needed and the timing device which is already incorporated in the magneto suffices for the purpose of directing the spark to the proper cylinders. A further simplification of the system is secured by taking the connections necessary for the operation of the system directly from the starting switch instead of placing another switch on the dash.

When the starting pedal is depressed the vibrating duplex system is thrown in. The coil receives current from the battery as soon as the starting switch reaches its first contact point. The coil is so constructed that it will operate down as low as 4 volts. In other words the functions of the secondary winding in the magneto are for the time being fulfilled by the little vibrating coil. The contact is made, broken and timed through the breaker box of the magneto in the ordinary manner so that as far as the wiring of the magneto is concerned no alterations are necessary. A wiring diagram is given in Fig. 5.

In case the starting motor for some reason should fail to work the new duplex system also works to advantage. The Bosch company states that a special switch can be built into the starting crank end of the engine so that when the crank is in-

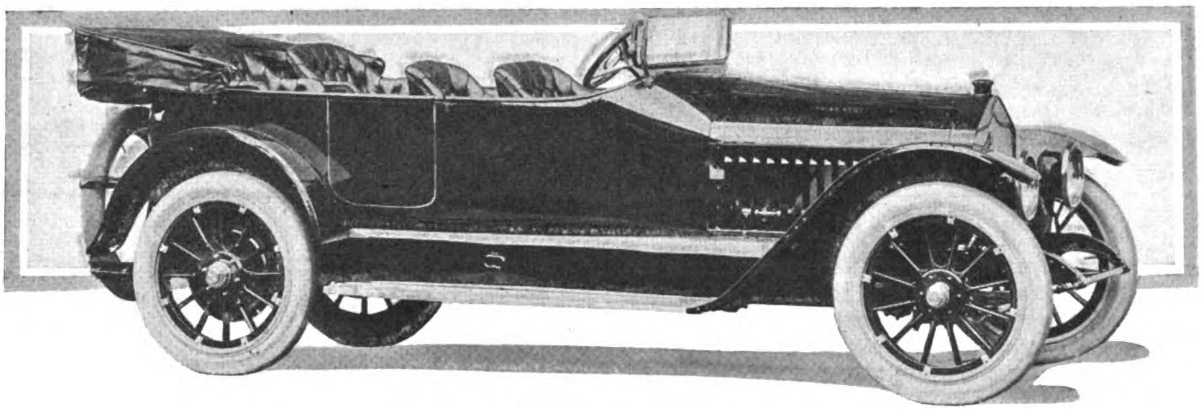
One Six—National Offering for 1915

This Chassis Continuation of Present Six—Boat Body Feature of Car—Five Other Body Types—New Electrical Equipment



New six-cylinder National with two-door boat body

FOR 1915 the National Motor Vehicle Co., Indianapolis, Ind., is building but one chassis, a six-cylinder type, which is a continuation of the 1914 design. This company, which for years has been a leading exponent of the four-cylinder design, is still bringing some of these through the factory, but after the present factory lot is shipped, four-cylinder styles will only be built on special orders.

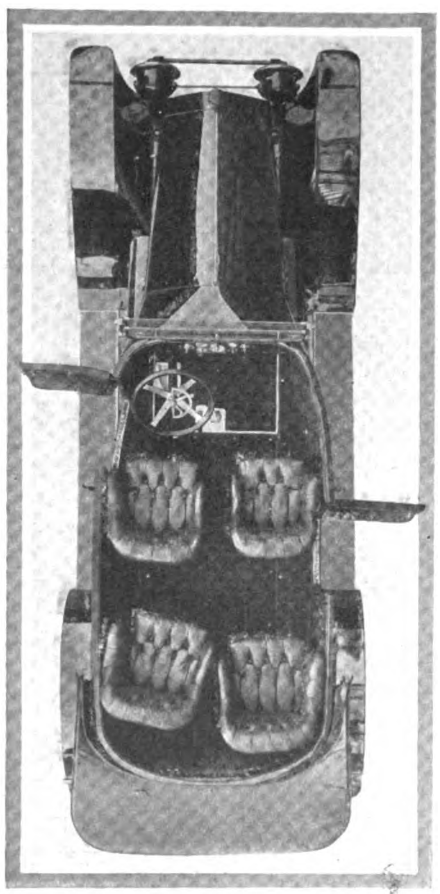
On the single chassis for 1915, not fewer than six different body types are fitted. Of these five are continuations of present styles with refinements, but the sixth is a new boat design which the company is introducing for the first time.

New Electrical System

The new cars are practically the same in price and essentially the same mechanically as the 1914, except for alterations as noted. Chief in these is an entirely new electrical equipment comprising the Eisemann magneto now used as the only source of current, and the Remy starting and lighting outfit, which replaces that formerly used. The Remy system is a 6-volt, double-wire one, with the starting and lighting units combined in one double-deck housing, but these are separate units so far as their operation is concerned. The cranking motor, a series-wound design, is capable of turning the engine at 100 revolutions per minute, even under adverse conditions. The reduction between the cranking motor and the crankshaft is 28 to 1.

Charges at 8 M.P.H.

As soon as the engine starts under its own power, the cranking motor is released and the engine drives the generator, which is the lower part of the double-deck unit. Between the generator and the crankshaft is a 2 to 1 reduction which allows the generator to start charging the battery at 8 miles per hour, and makes it capable of carrying the full lamp load at 12 miles per hour, at which speed the output is 12 amperes. The current regulation in the generator is by means of a bucking coil. Generator drive is by silent chain off the crankshaft.

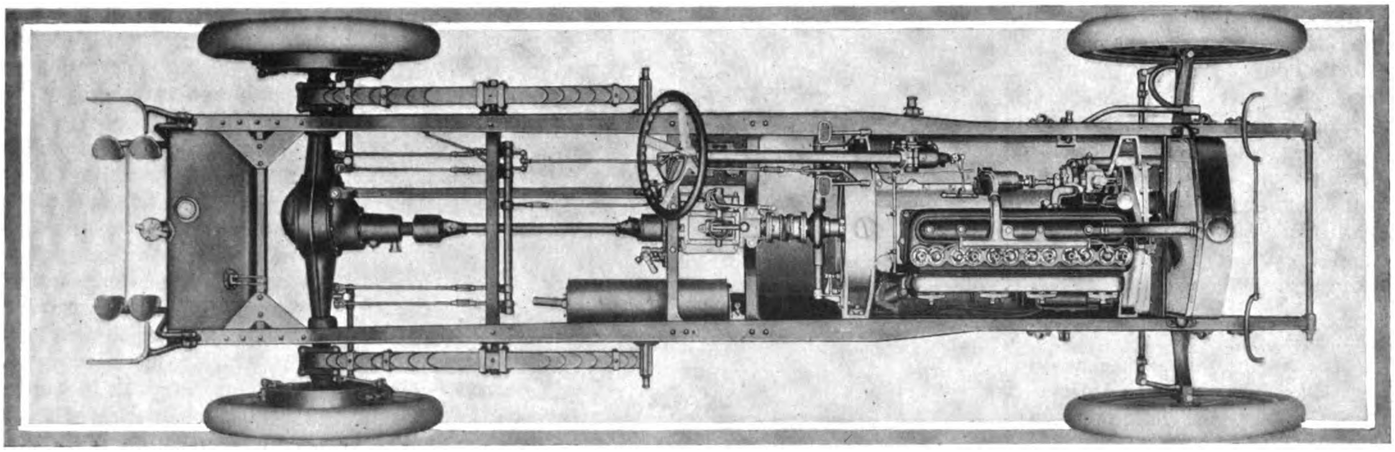


Plan view of boat body showing the novel arrangement of the doors and the individual chair seats that are movable

Most important in the body styles is that of the new boat type which was shown for the first time at the recent Michigan state fair. It has four deeply upholstered individual seats and one extra seat that folds into the rear extremity of the body. In form the body is similar to the upper part of the hull of a torpedo-stern motor boat. The four chairs are placed side by side, front and rear. Each chair is placed on a track that permits it to be moved forward or backward as desired. In addition there is a swivel arrangement by means of which the chair can be turned on its axis allowing the occupants to seat themselves tete-a-tete if they desire. The price of the new car fitted with the new body is $2,700.

In body work the streamline form has been adhered to throughout. The boat body is more extreme in this respect than the others. On all the other models the sides are straight while on the boat model it has a pronounced sweep. In addition to this body the company is continuing the four-passenger toy tonneau, five-passenger touring and two-passenger roadster, all listing at $2,375; a coupé at $2,750 and a six-passenger toy tonneau with disappearing seats, $2,500.

The cars are all fully equipped; tire pump, Collins curtains, extra demountable rim, windshield, horn, etc., being standard. Color is optional, but if not specified, National blue is furnished. Wheelbases of all but the roadster



Plan view of chassis showing the block motor, cantilever spring suspension and fuel tank location

model are 132 inches, the roadster model measuring 124 inches.

By following the modern trend in body work and making use of a mould rather than an angular body, the National company has in common with a number of other concerns, making a car of this size, clipped about 100 pounds from the body weight. In spite of this reduction in weight, the six-passenger body is longer and wider than in 1914. The extra seats fold into the backs of the front seats and are concealed when not in use by a leather flap that buckles over them. Another change is that the Willard battery is longer and narrower, making it possible to store it neatly in an accessible compartment beneath the splash guard.

Lighter Reciprocating Parts

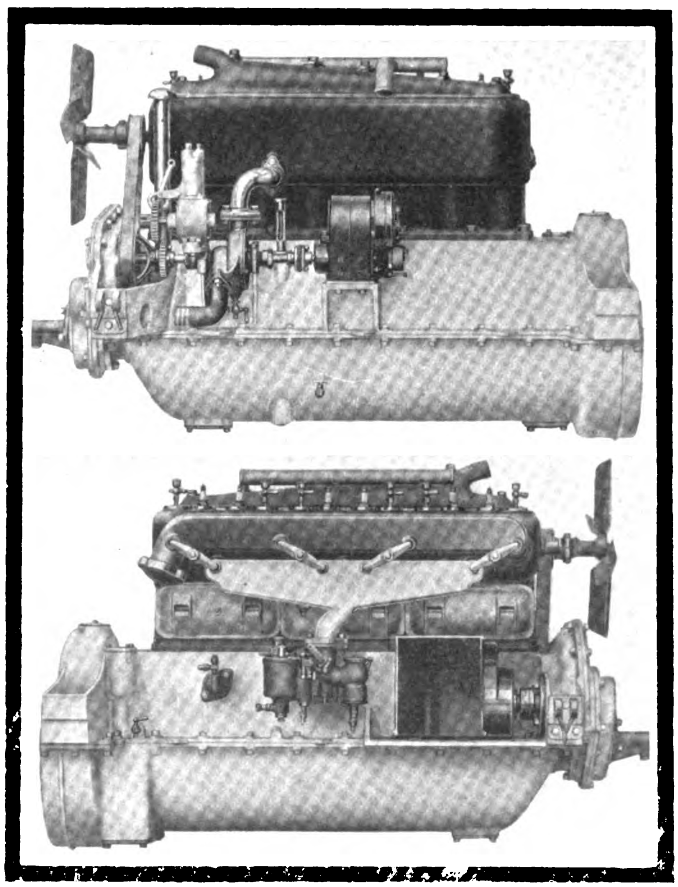
Twenty-five per cent. has been cut off the weight of the reciprocating parts of the motor for this season resulting in an increase in power and the elimination of vibration at high speeds. The crankcase is now a heavier casting adding still further to the rigidity of the construction. The oiling system remains the same in the principles of operation, but a vertical oil screen replaces the horizontal type and eliminates any chance of clogging because the oil cannot settle on the surface.

In the gearbox the travel of the sliding pinion has been increased by .25 inch. The purpose of this change is to make possible an easier gearshift. The bearings of the rear wheels are now larger. In place of carbon steel the springs are now of silico-manganese. Another alteration in the spring, which is a cantilever design, is that it is now practically flat, whereas on the former National the spring had a pronounced arch.

The 3.75 by 5-inch powerplant is a six-cylinder block design with L-head cylinders. The intake and exhaust manifolds are cast separately. The exhaust manifold is of gray iron. The intake is aluminum and is cored so that the waterjacket space registers with that of the manifold allowing the water to circulate about the intake passages to assist vaporization before entering the cylinders.

The waterjackets are arranged with baffle plates so that the water is led from a point beneath the valves where it enters and makes a circuit of each cylinder before reaching the outlet at the top. The cylinders are fitted with a cover plate that is removable, permitting of access to the water-jacket space.

The gray iron pistons are fitted with four rings, and have an oil groove and holes drilled to allow the excess oil to escape rather than to find its way into the top of the cylinder and cause smoking. The open hearth steel, case-hardened, piston pins are ground to their finished size, the holes are bored and reamed.



Upper—Left side of motor showing the location of the magneto water pump and power tire pump. Lower—Right side of motor showing the position of generator and arrangement of the piping

The connecting-rods, of open hearth steel, are I-beam in section and are drop-forged and heat treated. They are not offset and the upper bearing is fitted with a phosphor bronze bushing and the lower bearing is lined with babbitt against a bronze backing. Alloy steel bolts are used in holding the connecting-rod bearing caps in place.

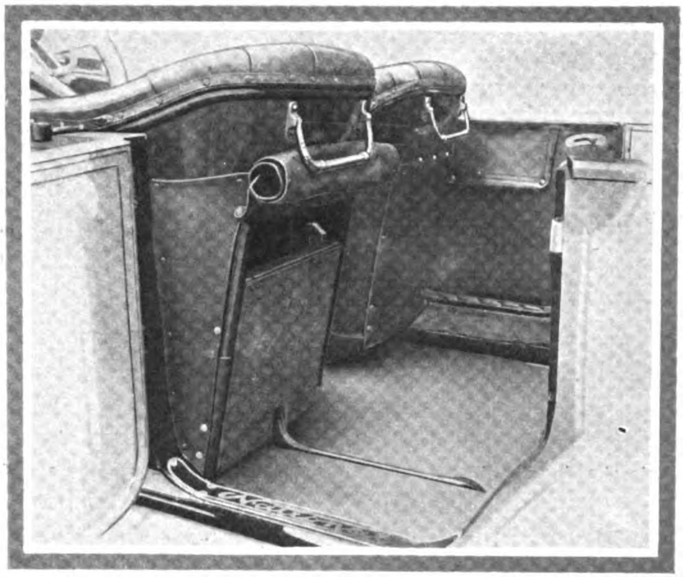
The crankshaft, also of open-hearth steel, is heat treated, and is balanced on a Norton running-balance machine. It is supported on four main bearings. Its diameter is 2 inches at all the bearing points except at the rear where it is enlarged to 2.125 inches to take care of the weight of the flywheel. The length of the front main bearing is 3.125 inches; of the two center ones, 2.5 inches, and the rear 4 inches. The diameter of the crankpins is 2 inches and the length of the crankpin bearings is also 2 inches.

The camshaft, carried on four bearings, has the front one made large to take the stresses of the drive from the timing gears. The connection between the cam gear and the shaft is made by means of a flange. The camshaft is completely inclosed and virtually runs in a bath of oil. The cams and shaft are a one-piece drop forging and the cams finished on a cam-grinding machine.

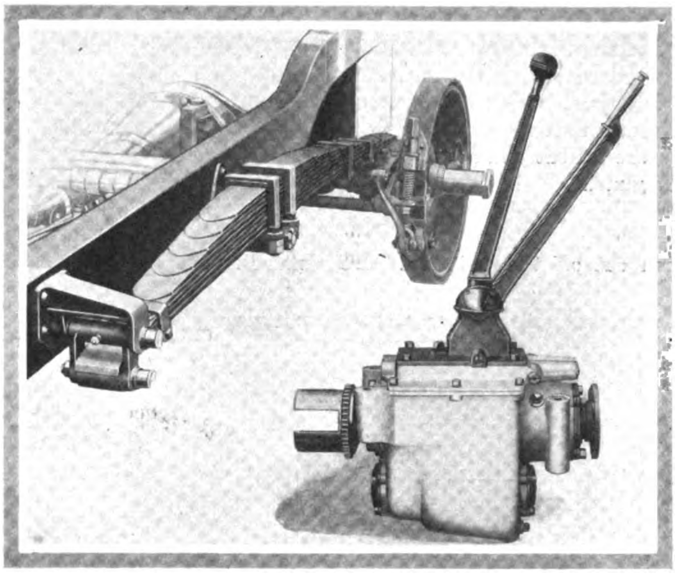
Valves All Enclosed

The entire valve mechanism is inclosed, the adjustment points being accessible by the removal of three cover plates. Each plate covers two inlet and two exhaust valves. The valves are of liberal diameter, 1 11-16 wide in the clear. The ends of the valve stems are hard and the push rods are of alloy steel. The stems and push rods work in separate removable bushings. The valve springs are oil tempered.

The oiling system is the same as that employed in 1914, in which the oil is carried in a reservoir in the lower half of the aluminum crankcase. From this reservoir it is pumped through a lead and separate tubes to each of the four main bearings. The oil which reaches the main bearings flows down on either side of the bearing into a series of splash troughs. When the level in these troughs rises to a certain height the excess is led back to the crankcase through overflow holes in the troughs. The filler tube for the oil reservoir is brought high up on the front end of the motor rendering it accessible. A float gauge is placed on the same side.



Method of concealing auxiliary seats on six-passenger body. They fold into the front seats and are covered by curtains



Cantilever spring suspension and gearset assembly

In the cooling system the centrifugal water pump placed on the left side of the motor at the forward end has the runner and bearings of bronze to avoid the tendency to corrode. Cooling is aided by means of a 16-inch steel fan, which is mounted on ball bearings. The fan bracket is movable for adjustment.

The gasoline system remains unchanged except that the newest Rayfield carbureter is fitted. This is the model G-3, 1.25 inch. The fuel tank is hung between the rear frame members and has a capacity of 21 gallons. The feed is by pressure, the pump for applying this pressure being mounted on the side of the motor and driven off the rear end of the camshaft. The gasoline tank is fitted with a gauge and the filler neck is extended back to provide for accessible filling.

Power is transmitted by means of a cone clutch, a type used in the National since its inception. Beneath the surface of the leather are flat springs which are compressed in engagement. These give a firm grip. The three-speed gearbox is the same design as previously used with the exception before noted on the increased travel of the shifter pinion. This increased

(*Continued on page* 608)

More Graceful Lines on Waverley

(*Continued from page* 577)

bearings and the inner sides are kept dust proof by means of felt washers. The other bearings throughout the car, notably in the motor and the transmission units are annular balls.

The spring suspension is unique in that it employs the seldom-used, five-quarter elliptic both front and rear. A layout of this suspension is illustrated herewith. The engineers claim for this type of suspension all the advantages of the full elliptic for softness and of the cantilever in the absorption of road shocks.

A double set of expanding brakes is used on all Waverley cars, and in addition to this the driver has at her or his disposal a third, and very effective brake on the motor. The latter is a band contact type and the differential acts very effectively as an equalizer when this brake is used.

The replacement of the previous four-chair brougham, known as the 107 by the 109 model keeps the Waverley line of passenger cars at five bodies. These with their selling prices are as follows:

Model	Body	Price
109	Four-chair brougham	$3,150
104	Front drive, four passenger	2,900
105	Rear drive, four passenger	2,800
108	Limousine, five passenger, forward drive	3,500

The body work on the new model is the result of a special effort to put out the most luxurious possible town car at the price. The roof and panels are of aluminum. The length of the car over all is 149 inches, the extreme width 66 inches. Of the length 131 inches is taken up by the body. The wheelbase is 106 inches. All four seats are large enough to accommodate people of more than average stoutness. Two of the rear seats are 18.5 by 20 inches, the other rear seat is 23 by 20 and the driver's seat is 18 by 15.5. The road clearance is 10 inches and the step to the ground 14 inches.

The upholstering work is optional. It may be in any of the imported corded fabrics or of special limousine leather. The standard color is black with majestic blue panels, but the car will be painted to suit the demands of the individual. The tires are 34 by 4 inch front and 34 by 4.5 rear. They may be cushion or pneumatic at the same price.

New Velie Six, $1,595—Other Models

(*Continued from page* 591)

Propulsion in this new six is through the springs constituting what is commonly called the Hotchkiss drive. As assurance that the springs will not be overburdened the main leaf is made of alloy steel. The front springs are 40 inches long and the rear 52 both having leaves 2 1-4 inches wide. The wheelbase is 124 inches and the wheels fitted with 34 by 4 inch tires on Goodyear endless demountable rims for straight-side tires. The front wheel camber is 1 1-2 per cent.

The high spots have been reached in the matter of body style and equipment. The Biltwel body is the exemplification of the streamline idea. There is a graceful curve from cowl to a new-type of rounded radiator the sides are straight and the back, bell-shaped. The symmetry of the car has not been broken up by anything, for the designers have gone so far as to install a 20-gallon cylindrical gasoline tank in the rear. The top when folded back and covered gives a clean appearance for the top-cover also protects the bows. A feature of this body as well as the others of the line is that they are fitted with anti-squeak strips. Many owners who have had experience with new cars know that many cars will emit body squeaks for the first few months they are in service, but this inconvenience has been eliminated in the Velies by the use of strips at points where squeaks might occur.

No wires are attached to this body, hence it is an easy matter to remove the body without disturbing the wiring. This is due to the fact that a junction box to which all wires are attached, is employed.

Nothing seems to be lacking in the list of equipment. Besides the ordinary accessories, given, the new six is equipped with a Taylor Noil tire pump, a windshield with supports fastened to the body sills, auxiliary emergency battery for ignition, double headlights, gasoline gauge, inspection lamp, tire carrier, and electric horn with control button in the center of the steering wheel.

Two Bosch Magnetos—One Has New Distributer

(*Continued from page* 593)

serted in its place it automatically closes the circuit and throws the vibrating coil into operation. It must be understood, however, that the system is not intended to displace the separate battery system as a source of running current. It is merely for starting purposes and at all other times is not in use.

One of the chief uses for a system of this nature is for women drivers who through the failure of the starting system due to a nearly-discharged battery are compelled to fall back on the starting crank. In an incident of this kind the motor could readily be started with a turn of the crank provided at least 4 volts are available.

Cars not equipped with starting motors can also make use of the system to provide a means of easy starting without an entirely independent battery ignition. It is also possible to eliminate dash complications in the installation of the switch when there is no starting switch to make use of. A wiring diagram showing how this can be accomplished is given in Fig. 6. Only one wire running from the switch to the magneto is employed. When the switch is in the off position, this wire conducts the battery current from the vibrating coil to the magneto primary, thereby assisting the magneto at low or starting speeds. Fig. 3 shows the component parts of the system including the switch which can be built into the starting crank end of the motor.

Seven Passenger Pathfinder for $2,322

One more model has been added to the Pathfinder line. This is a seven-passenger car of distinctive design selling at $2,322. It is mounted on the standard Daniel Boone chassis, which was fully described in THE AUTOMOBILE, June 11. The extra tonneau seats on this car fold forward into the backs of the front seats.

Scenes Near Paris—From An Automobile

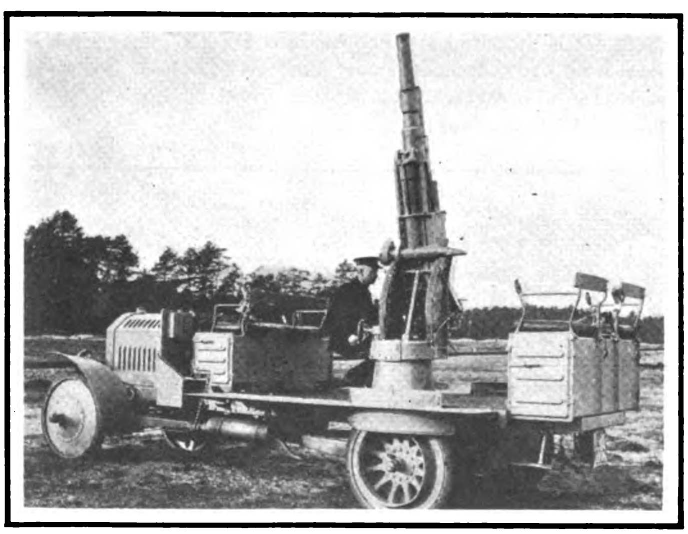
Roads from City Crowded With Refugees—Main Routes Barricaded—Buses for High-Speed Transport—Traveling Difficult

By W. F. Bradley

PARIS, Sept. 15—Playing at last out of Paris was a somewhat risky business, for nobody knew exactly at what moment the doors would be shut, holding those on the inside prisoners and making it difficult for those on the outside to get back again. Having placed an automobile just on the outside of the fortified wall, I was able to get away after the official shutting down of the city in preparation for a state of siege.

This was touring under full war conditions. Before I had been on the road 5 minutes a Maurice-Farman armored biplane was seen making its way over Paris.

That main road out of Paris was crowded with peasant refugees, obliged to leave their homes within the line of fire of the forts. In their lumbering wagons they carried everything they could possibly save: bedding, pieces of furniture, hens, ducks, rabbits, goats, birds. Such cattle as they possessed followed. Of automobiles there were none. Nearly everybody possessing a car had fled from Paris when the first alarm had been given that the city might be invested.



Special aeroplane gun mounted on a Mercedes truck

Ten miles out the scene changed. As everybody is aware, there is a belt of forts around Paris, each fort being connected up with its neighbor by suitable entrenchments. Naturally the forts themselves are invisible, but I was soon aware that I was in their neighborhood by a soldier appearing in the middle of the road and pointing a bayonet at my radiator. The road, which is dead straight at this point, was blocked by strong earthworks thrown up to a considerable height. There were two barriers, each one occupying half the road, but separated one from the other by about 8 or 9 yards. It is possible for vehicles to zigzag through, but no car could get through by surprise.

The main road being forbidden, a detour had to be made through country lanes. This brought me into sight of scientifically cut trenches in the beetroot fields. They were so disposed that one would never have suspected their presence even at a distance of a few yards. Half an hour on the lanes, and I was back again on the main road, still cut up by barricades. At frequent intervals a soldier stepped out, examined my papers, and ordered me on.

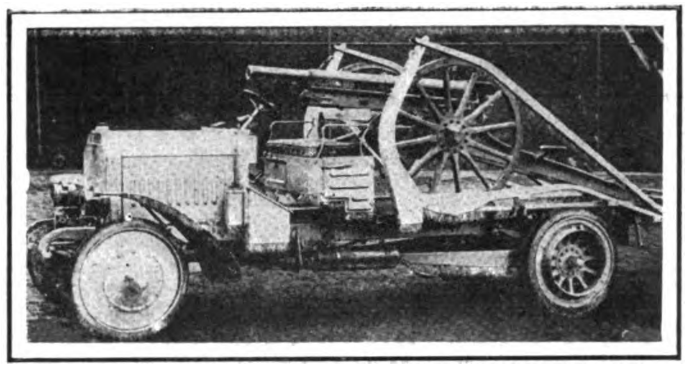
A couple of miles further on I had to draw in to one side to allow the passage of a convoy of Paris motorbuses transformed into meat wagons. They traveled in a procession of half a dozen each with the regularity of a train. All the bright paintwork had gone, the bodies were scratched and battered, but the mechanism had been kept in the best of condition. It is testified by all that these motorbuses are doing excellent work in keeping the troops supplied daily with fresh meat. They contribute considerably toward the rapid movements of troops necessary under modern war conditions.

A civilian traveling through a war ridden country cannot hope to maintain a high average. But even 15 miles an hour on a day's run is better than 5 or 6 miles on the few trains given up to non-combatants. A batallion of military cyclists had to be overtaken. It is a matter of time and patience, particularly when army trucks come along in the opposite direction from time to time, and it is necessary for the civilian to lose all the ground he has gained to give the army the right of way.

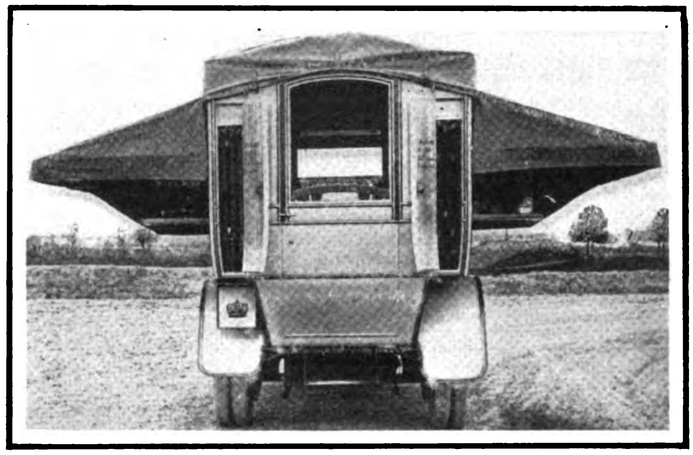
Late in the afternoon an important body of troops was met on their way to take up positions on the hills dominating the valley. It was necessary to get on the grassy bank and give them the whole of the road. For nearly an hour I had to stay there while cuirassiers, dragoons, artillery and stores passed along. The line of troops was broken from time to time by a convoy of automobiles.

The value of the French subsidy system was apparent in this service. All these vehicles had been requisitioned in the North of France, as was evident from the names of the owners on the bodies, and were put at the disposal of the troops who happened to be stationed in that neighborhood. They were all 2 1-2-ton Latil models, and although they came from different businesses the fact that they were of uniform power, speed, and capacity made it possible for them to give excellent united service.

It was necessary to cross the river Seine by ferry, at a point which shall also be nameless. To get to the river side required a considerable amount of patience and diplomacy. The civil guards on duty there would have much preferred a local pass to the one issued by the head authority in Paris. When they had been convinced against their will, I was taken over. At the same time a convoy of British motor lorries was crossing in batches of three and four. In conversation with the drivers it was learned that the army had got over its first difficulty by abandoning the vehicles which were not suitable for service in France. At the outset a number had been sent over without sufficient examination, and by reason of mechanical defects had become a drag on all the others. One division had abandoned fifty of these derelicts. Owing to the language difficulty and to the lack of knowledge of the country, the British vehicles had to be much more closely convoyed than the French. Each group had attached to it some type of car with an officer interpreter aboard. The French had no need of such service, and were only attended when operating in dangerous country.



Method of carrying artillery used by the German army



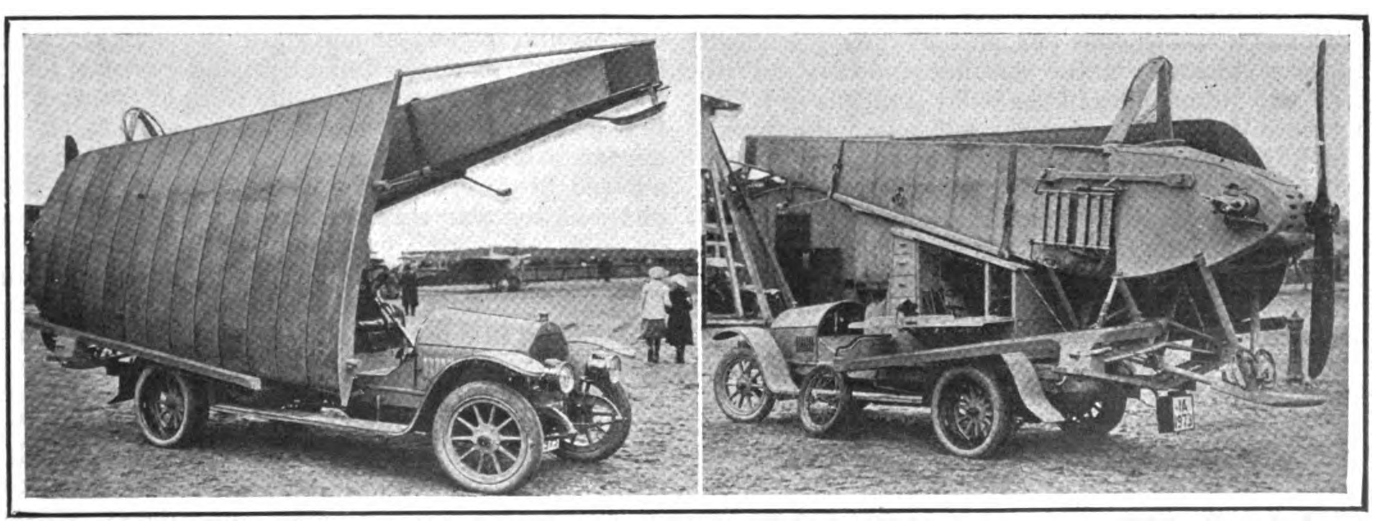
Special field kitchen employed by the Kaiser

Racing Drivers Have Important Rôles

PARIS, Sept. 1—Rene de Knyff, chairman of the Racing Board of the Automobile Club of France, who is of Belgian origin, has just been granted French citizenship and has been accepted as an automobile volunteer in the French army. De Knyff is driving a powerful Panhard-Knight and has with him as chauffeur M. Artauld who did some very fast work on a Panhard in the recent Boulogne meet. This car is working between Paris and the eastern frontier.

Arthur Duray, who is also of Belgian origin, has been accepted as a volunteer automobilist in the French army. Duray offered his services as soon as war broke out, but regulations obliged him to wait until the twentieth day. When he had donned the blue uniform and slung a revolver case over his shoulders he took the wheel of a Turcat Mery car and was sent the same day to the eastern frontier. Duray went with his usual boisterous joyfulness.

Practically all the men who took part in the recent Grand Prix at Lyons are now under military orders. The full Peugeot team is represented: Boillot and Rigal are driving cars; Goux is an artilleryman at Belfort. The Delage team has Duray and Guyot at the front, Bablot in the reserve, and Chief Engineer Michelat in charge of the headquarters staff automobile reserve. Champoiseau and Gabriel of the Schneider team are at the front. Tabuteau of the Alda Company is an aviator. Rene Thomas, the Indianapolis winner, was not eligible for military service and has been making every effort to be accepted as a volunteer. He has only just succeeded.



German monoplane mounted on a powerful Benz chassis. The wings are folded on one side and there is space for tools and repair parts

$20,000,000 from Gasoline

THE government purposes by its emergency war tax measure to raise $20,000,000 revenue in 12 months from its tax of 2 cents per gallon on gasoline, motor spirits, naphtha and every other motor fuel which can be used in hydro-carbon engines.

According to the present scheme of taxation, the gasoline motor industry is to pay approximately one-fifth of the entire emergency war tax, which it has been estimated will approximate $100,000,000 or not more than $120,000,000 per annum.

This is a tremendous burden that the government purposes placing on the gasoline industry. With 1,500,000 automobiles in use today it means in round numbers that each motor car will average approximately $15 or more. A large share of this burden will fall on commercial vehicles which are used in the regular avenues of industrial transportation.

The automobile industry has been one of the most progressive and revolutionizing industries of the current century, and it is rather unnatural to look for one of the vital industries of the country to pay so heavily for an emergency war tax. Every citizen expects that luxuries should be taxed, in fact, that they should pay the majority of the tax, but here we find a new industry being called upon to carry nearly one-fifth of the entire burden.

The present schedule of taxes as drafted by the Ways and Means Committee places a burden on one form of transportation but not on another. In a word, if the transportation of passengers and freight is to be taxed, then all means of such transportation should be taxed alike. If we tax gasoline we should tax coal, we should tax wood, we should tax electric current, we should tax natural gas, we should tax producer gas, we should tax all of the provender consumed by horses and other animals of transport; in fact, we should tax everything that serves as a fuel or force in transportation.

There is no reason why the gasoline motor vehicle should be selected as one particular form of transportation to pay a war revenue tax. The gasoline vehicle is as much a utility today as the steamboat crossing the ocean, as our limited trains, as our freight trains, as our trolley cars, as our horse trucks, as our horse cabs, in fact as any means of transportation. None of these can be looked upon as luxuries; they are necessities.

The present European war is proving that the motor vehicle is one of the great factors in it. This is the first great motor war. The motor vehicle is superceding the horse in practically every arm of the service except cavalry. Why then, in all fairness, should we tax the gasoline which these vehicles use, and not tax the gunpowder used in the ammunition in the war, not tax the food used by the men fighting on either side, not tax the Red Cross supplies which are playing their part in the war.

The present agitation for a tax of 2 cents per gallon on fuel is both unreasonable and unjust. The makers and users of gasoline motor vehicles stand prepared to carry their share of this war revenue tax, but they do not stand prepared to carry one-fifth of it and let other means of transportation not using gasoline as a fuel go free. This is a case which calls for plain justice. If the gasoline truck hauling gravel for the contractor must pay a tax of 2 cents per gallon on its fuel, then the trolley car on the city street should pay its ratio on electric current used; then the electric truck used in hauling freight must pay its share; then the passenger and freight elevator in the skyscraper must pay its share. The owner of the horse vehicle who drives down Fifth avenue to his office must pay his share. All must contribute if one contributes.

This is a movement in which manufacturers, dealers and owners should unite in using their influence, not in opposition to raising revenue for a war tax, but in objecting to one form of transportation being singled out to carry such a share of the burden while other forms of transportation are allowed to go scot free. They should oppose this phase of the war revenue tax on the ground of the injustice of levying on such a necessity in life as transportation. It enters into every phase of our existence. It plays its part in all of the food we eat. It is needed in our every movement in life excepting when we walk, in both business and in pleasure. Transportation is the life blood of the present age. It is the greatest movement of the centuries. We have no more right to tax it than to tax the telephone, the telegraph, the wireless, or the post office, or parcel post. All are alike. All are equal in the mission they have to perform.

Congress May Tax Gasoline 2 Cents

WASHINGTON, D. C., Sept. 21—*Special Telegram*—The war revenue tax bill introduced into the House today provides a tax of 2 cents per gallon to be assessed against the producer on gasoline, naphtha, and other products used for motor power. Should this tax be imposed it will mean that approximately one-fifth of the total war revenue tax will be raised from this 2 cents per gallon on different fuels for motor use.

If this provision is enacted into law, the method of collecting the tax will be in accordance with the rules and regulations formulated by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury. The bill is to become effective on the date of passage, but the stamp tax section will remain in operation only until December 31, 1915. The tax on gasoline evidently will remain in force indefinitely.

The war revenue tax bill will be taken up in the House of Representatives on Sept. 24 under a special rule to make it a privileged matter. An effort will be made to limit debate on the measure. According to information from the ways and means committee gasoline will be taxed 2 cents a gallon, but there is a probability that the Senate will throw this out of the bill and substitute some sort of a federal tax on motor cars not used in business.

The proposition to put a tax on gasoline is sure to arouse a storm of protest, and while the House may jam the proposition through, it is believed almost certain that the Senate will vote to eliminate the House provision. The matter will then go to conference and some highly interesting developments may be looked for.

The measure, as it will be presented to the House of Representatives, contains scores of items to be taxed, many of them taken bodily from the Spanish war tax of 1898, but a welcome relief to business men is the absence of a stamp tax on checks. The members of the Ways and Means Committee left out this troublesome item because it had been found by Treasury Department experts that the business of the country had increased to so great an extent that items other than checks could be taxed slightly and bring up the total of the bill's results to about $105,000,000 in a year.

Republican members of both the House and Senate have gone on record in opposition to any war tax measure. The Democrats hope to rush the bill through the House and the big fight against the bill will be in the Senate.

Just what sort of a tax the Senate will attempt to place on pleasure motor cars is unknown at this time. Members of the finance committee, which will handle the Senate bill, decline to give any information on the subject.

The emergency war tax bill was ordered reported to-day by the Ways and Means Committee and will be called up in the House Thursday. The Rules Committee will meet tomorrow to frame rules to rush the bill through the House committee. The Democrats added an amendment to the gasoline section, the words motor spirits being added so that the section will embrace all products used for motor power. The committee expects gasoline to produce $20,000,000.

Important Papers Scheduled for Truck Convention in Detroit

NEW YORK, Sept. 22—The first draft of the program for the Motor Truck Convention to be held in Detroit, Mich., October 7, 8, 9 and 10, shows that papers of particular interest will be handled by representatives of the different truck makers on all days of the convention. The Wednesday afternoon program is framed largely for truck manufacturers. On Thursday the papers scheduled are of special interest to both manufacturers and dealers. Friday is dealers' day and the subjects on the program for that day treat with practically all the difficult problems that the motor truck dealer is face to face with.

No other subject will attract greater attention than the tire question for motor trucks which is scheduled for Thursday, October 8. J. E. Hale, of the Goodyear Company, and S. V. Norton, of the Goodrich company, are listed to handle different aspects of the truck question.

Such important questions to motor car makers and dealers as traffic engineering, how to calculate costs, the trading evil, etc., are the subject of papers by well qualified truck manufacturers.

Up to this date the entire program is not complete, but the program as promised by the different representatives who have been asked to assist is as follows:

WEDNESDAY, October 7. Afternoon Session—2:30 to 5:30:—Time Payment Plans for Trucks, Walter B. Parker, Commerce Co., Detroit, Mich.; Territorial Lines for Dealers, T. R. Lippard, Stewart Motor Corp., Buffalo, N. Y.; Evils of Overloading and Overrating for Trucks and Permissible Body Rates, H. W. Alden, Timken-Detroit Axle Co., Detroit, Mich., and John Utz, Perfection Spring Co., Cleveland, Ohio.

THURSDAY, October 8. Morning Session—9:30 to 12:30:—Lists, Discount for Quantity Business, Discounts for Parts, etc., M. L. Pulcher, Federal Motor Car Company, Detroit; Traffic Engineering, R. W. Hutchinson, Sternberg Mfg. Co., Milwaukee, Wis., and E. L. Shoemaker, Denby Motor Truck Co., Detroit, Mich.; Export Selling Methods and Requirements for Motor Trucks, J. B. Crockett, New York City.

THURSDAY, October 8. Afternoon Session—Sales Assistance to Dealers, C. W. Moodie, Standard Motor Truck Co., Cleveland, O.; Standard Tire Sizes, J. E. Hale, Goodyear Tire & Rubber Company, Akron, O.; Cost and Evils of Overloading and Overspeeding in the Truck Tire Field, S. V. Norton, B. F. Goodrich Co., Cleveland, O.

FRIDAY, October 9. Dealers' Day—Manufacturers' Guarantee of Service to Owners, W. L. Day, General Motor Truck Co., Pontiac, Mich., will champion this from the makers' viewpoint, and J. H. Thompson, Thompson Auto Co., Detroit, Mich., from the dealers' viewpoint: Central Market Reports, H. M. Allison, Chicago Auto Traders Exch., Chicago, Ill.; The Trading Evil, W. K. Chilcott, General Motors Truck Co., Pontiac, Mich.; Demonstrations, necessity and Charges, J. A. Ayers, General Motors Truck Co., Detroit, Mich.; The Driver's Relation to Successful Motor Truck Operation, C. P. Cary, Federal Motor Truck Company, Detroit, Mich.; How to Calculate Costs, R. W. Hutchinson, Sternberg Mfg. Co., Milwaukee, Wis.

Olympia Show Abandoned

LONDON, ENGLAND, Sept. 21—*Special Cablegram*—Owing to the war, the annual Olympia show, scheduled for November, will not be held. The Institution of Automobile Engineers will carry on its regular program of sessions but all papers will as far as possible have relation to the position of the industry in regard to the war.

The sale of light cars for home use is practically dead. Export trade, however, in light cars is fairly brisk and it is only this trade that is keeping the factories building small cars, open.

Such firms as Rolls-Royce, Siddeley, Starr, Austin, and others making small cars are today turning their attention to the construction of commercial vehicles, and other firms building passenger cars are doing machine work for the makers of heavy commercial vehicles. A considerable proportion of all plants is employed exclusively for government contracts.

The commercial vehicle industry is booming. All types of commercial vehicles with a load capacity of under 3 tons are finding ready sales, these naturally going to business houses to substitute horse haulage.

All builders of commercial vehicles of 3-ton capacity and over, such as, Leyland, Thorneycroft, Dennis, Straker, Karrier, Page-Field, Maudslay, Wolseley, and Daimler, are busy in the construction of vehicles for the government. The supply does not meet the demand. These companies have generally turned their entire factories over to the commercial vehicle use, that is, where a fraction of the factory has been engaged in making passenger vehicles, this fraction is now manufacturing trucks.

Greece to Purchase 300 Trucks

NEW YORK CITY, Sept. 22—There is now before the War Department of the Greek Government a project to purchase between 300 and 400 motor trucks at a cost of $1,000,000 to $1,200,000. The Kissel Motor Car Co., Hartford, Wis., last week shipped 50 trucks to that country.

Cars Preempt Farm Machinery at Wisconsin State Fair

Many Cars Introduced in Mammoth Machinery Hall—A Special "Automobile Day" —Many Factory Men at the Exhibit

MILWAUKEE, WIS., Sept. 19.—The display of motor cars at the 1914 Wisconsin State Fair at Milwaukee from September 14 to 18, inclusive, was the most pretentious exposition of this kind that the State Board of Agriculture, managing the fair, has yet been able to muster. The mammoth concrete Machinery Hall was filled with car exhibits, which crowded out the usual farm gas engine and power machinery displays of former years and obliged these to go into tents adjoining. As a further recognition of the motor car, the board of agriculture set aside one full day as Automobile Day.

This was the first time that the fair board really went out to muster exhibits of cars and the result is so satisfactory that there is no doubt that with a little more work the board can present a motor show each September that will rival or excel the big Milwaukee show in the Auditorium every January. The display last week brought to Milwaukee nearly as many big factory men as the winter show and it cannot be questioned that the state fair show showed better pecuniary results than the winter show can ever hope to, by reason of the enormous number of prospective buyers, farmers and up-state city folk who visit the fair each year.

The fair show served to introduce to Milwaukee and Wisconsin people a large number of cars never seen before or never shown in public expositions prior to this time. This class included the Briscoe, Lewis VI, Haynes light six, the new R. C. H., the new Mitchell light four, the new Imperial light four, the Jeffery Chesterfield six, the new King, Oldsmobile, Moline-Knight, Paige, Chandler, Chevrolet, Reo, Stan-Ford, Cartercar, Regal, KisselKar, Oakland, Overland, Hupmobile, Moline-Knight, Paige, Chandler, Chevrolet, Reo, Stanley steamer, Buick, Case and Detroiter.

The truck division was a feature, and displays were offered by the Stegeman, Menominee, Crown, Jeffery, Reo, Kissel, Overland and Buick. The Jeffery Quad gave exhibitions of its marvelous powers and abilities in mud, sand, ruts and hills in a special plot of ground in the fair park.

Big Interest in Cars at Canada Exposition

TORONTO, ONT., Sept. 10—In spite of the strain imposed by the conflict in which the mother-country is engaged, Canada and Canadian financial conditions are well reflected in the Canadian National Exhibition held in this city.

When the Canadian National Exhibition opened, on August 31, 4 weeks after the declaration of war, Canadian trade anxiously watched with what enthusiasm the public would become interested. Results were most satisfactory. Under normal conditions, about 1,000,000 people visited the exhibition, coming from all parts of Canada. The first week, because of unpleasant weather, the attendance was not up to standard, but the second week motor cars, the barometers of public confidence, indicated by the amount of interest centered upon them that Canada was bearing up and that the automobile trade for the coming year would find it, as ever, an excellent market.

At the close of the exhibition, the exhibitors almost to a man declared themselves very well pleased with results and sales and expressed the belief that the outlook for a good year's business in the automobile trade could not be brighter under the circumstances.

Henderson Bros. Rejoin Cole Co.

INDIANAPOLIS, IND., Sept. 23—*Special Telegram*—C. P. Henderson and his brother, R. P. Henderson are again to be associated with J. J. Cole in the Cole Motor Car Co., this city. The Hendersons will be in charge of sales and advertising as in the past, taking up their new duties October 1. Homer McKee, former sales and advertising manager of the company, is entering the advertising business on his own account and will continue to handle the Cole account in connection with the Mahin Advertising Agency.

46 Cars to Be Shown at St. Louis Show

ST. LOUIS, MO., Sept. 20—At the eighth annual automobile show which will be held at Forest Park Highlands, October 5 to 10, under the auspices of the St. Louis Automobile Manufacturers and Dealers Assn., space has been drawn for the following 46 different makes of gasoline cars:

Oldsmobile, Metz, Empire, Jeffery, National, Lyons-Knight, Havers, Crescent, Studebaker, Paige-Detroit, Premier, Lozier, Mitchell, Hupmobile, Cole, Empire, King, Oakland, White, Jackson, Kissel Kar, Regal, Stevens-Duryea, Meteor, Buick, Pierce-Arrow, Packard, Ford, Dorris, Hudson, Reo, Chevrolet, Locomobile, Chandler, Overland, Marion, Peerless, Mercer, Franklin, Marmon, Winton, Chalmers, Saxon, Stearns-Knight, Auburn and Velie. There will also be shown the following electric vehicles: Waverly, Woods, Rauch & Lang, Baker and Detroit electric.

J. C. Weston Made Tire General Sales Manager

NEW YORK CITY, Sept. 22—Joseph C. Weston has been made general sales manager of the United States Tire Co., succeeding J. D. Anderson, who has resigned. Although the title is new to Weston, who long has been connected with the United States company, latterly as Central District Manager, his duties will not be strange to him, for during the past few months he has been acting general sales manager in the absence of Anderson in Europe. For the present, Anderson will remain in an advisory capacity.

Weston's prominence to the head of the sales organization is a logical one for he has a veteran's experience in the tire business, dating back to the old Morgan & Wright days. For years he was secretary of the Morgan & Wright Co.; when the United States Tire Co. was formed he was appointed Western district manager, his headquarters being in San Francisco. Later, he was appointed Central district manager, succeeding A. I. Philp.

Weston is exceedingly well-liked in the trade both for his universal good nature and ready smile and for his business acumen. There are few men in the tire business who are better known to the trade in general.

General Motors Sells More Cars; Margin of Profit Cut

NEW YORK CITY, Sept. 19—The annual report of the General Motors Co., for the year ended July 31, 1914, shows gross sales of $85,373,303, as compared with $85,603,920 for 1913. The 1914 sales represent the sale of 10 per cent. more cars at correspondingly lower prices. The net profits were $7,947,413, a decrease of $336,727 from last year's figures. The balance after the payment of the accrued interest on the 6 per cent. notes was $7,249,734, or a loss of $209,737, while the undivided profits, after the payment of the preferred dividend, were $6,201,055, a decrease of $209,882. This added to the previous profit and loss surplus made a total of $9,146,434, a gain of $1,472,902. There was charged off $2,457,007, leaving a final profit and loss surplus of $6,689,428, an increase of $3,744,048.

The total value of the real estate, plants and equipment appraised at $21,515,065.26 is entered for a net amount of $15,432,916.58 the difference or $6,082,148.68 being reserved for depreciation. For patents, agreements, etc., there is recorded $471,200; for miscellaneous investments, $352,734.50; the total current and working assets, $28,841,402.02. A total of $7,934,198.14 is marked as good will and is explained as being the excess of the appraised value over the book value of the capital stock of the subsidiary companies, less the reserve.

President Nash in his statement to the stockholders says:

"The net profits of $7,947,412 are, after deducting all expenses of General Motors Co., and also after deducting $944,099, a sum deemed sufficient to cover depreciation of buildings and equipment.

"In view of the considerable undivided surplus income for the year your directors have deemed it wise to write off $972,419 from the book value of patents, agreements, etc., and also to appropriate from surplus the sum of $1,483,208 as an additional reserve for depreciation of plants and equipment. The above amount written off from patents, agreements, etc., comprised the entire sum carried in that account by all subsidiary companies except the McLaughlin Motor Car Co., Ltd. General Motors Co.

owns slightly less than one-half the capital stock of that company, whose agreements, etc., $471,200, are being written off in annual instalments.

"The sole outstanding funded debt of the company July 31, 1914, consisted of $7,852,000 6 per cent. first lien notes, maturing Oct. 1, 1915, being unpaid balance of the original issue of $15,000,000 of these notes dated Oct. 1, 1910. In September, 1913, the company paid the balance of $1,000,000 due Oct. 1, 1913, on account of the sinking fund, and in the spring of 1914 paid in advance the full $2,000,000 sinking fund instalment due Oct. 1, 1914. This $3,000,000, together with interest thereon and a small additional payment from the proceeds of property sold, was applied by the trustee to the purchase of $3,083,000 notes, leaving outstanding $7,852,000.

"Aside from these notes, the only indebtedness of the company and its subsidiary companies on July 31, 1914, consisted of current accounts payable of $3,772,123, composed wholly of the normal obligations for merchandise, etc., and $1,000,247 liabilities accrued, but not due, for pay-rolls, taxes and interest on funded debt.

The income account compares as follows:

	1914	1913	1912
Net profit sub. cos.	†$7,947,413	$8,284,140	$4,838,449
Gen. Motor's share	7,819,968	8,184,053	4,746,757
Interest on notes	570,235	724,581	850,463
Surplus	7,249,734	7,459,471	3,896,293
Preferred dividend	1,048,679	1,048,034	1,040,211
Surplus	*6,201,055	6,410,937	2,856,088

*Equal to 37.57 per cent. on $16,501,783 common stock as compared with 38.90 per cent. on $16,476,783 previous year.

†After deducting manufacturing, selling and administration expenses and maintenance and depreciation.

The profit and loss account follows:

Profit and loss surplus July 31, 1913	$2,945,379
Surplus for 12 months to July 31, 1914	6,201,055
Total	9,146,434
Plants and equipment	1,483,208
Patents, agreements, etc	972,419
Sundry adjustments	1,380
Total deductions	$2,457,007
Profit and loss surplus July 31, 1914	6,689,428

The consolidated balance sheet of General Motors Co. and subsidiary companies directly connected with the manufacture of automobiles and parts, as of July 31, 1914, compares as follows:

Assets

July Exports Only $500,000 Less than Year Ago

Exports for 7 Months Also $500,000 Lower —Increase in Exports of Gasoline

WASHINGTON, D. C., Sept. 20—Automobile exports from this country for the 7 months ending July, 1914, have fallen off $500,000 compared with 1913, or from $17,760,733 to $16.818,422, about 3 per cent., though there has been a very slight increase in our export of commercial vehicles. For the respective months of July, 1913 and 1914, exports were $1,736,253 as against $1,249,819, a decrease of almost $500,000.

For the 7 months ending July, 1913 and 1914, gasoline exports, however, have increased 70 per cent., or about $5,000,000, the value going from $7,445,589 to $12,621,406.

Tires fell off from $379,273 in July, 1913, to $341,617 in 1914, the total 7 months showing a decrease of from $2,545,169 to $2,102,092.

Imports of motor cars also decreased in 1914. Comparative figures for the months of July show $81,678 for 1913, as against $26,168 for 1914. The total for the 7 months is $768,521, as against $178,631. Automobile parts imports, however, went from $151,856 to $602,829.

DETROIT, MICH., Sept. 21—The usual semi-annual dividend of 3 1-2 per cent. on its preferred stock has been declared by the General Motors Co. It will be paid November 1 to stock on record October 15. The company will mail checks.

Mayor Mitchel Vetoes Separator Repeal

NEW YORK CITY, Sept. 21—The ordinance requiring the use of separators in garages, to keep gasoline and oils from leaking into the sewers, is still in effect, the Mayor having recently vetoed the bill placed before him by the Board of Aldermen, which would have repealed this ordinance.

The only alternative for the garagemen and dealers, who are conducting the fight, is to take the matter again to the Board of Aldermen and ask that they pass a new bill over the veto of the Mayor. To do this a favoring vote of two-thirds is necessary.

Those fighting the bill claim that little or no gasoline leaks into the sewers, and what does is greatly diluted by water. That the explosions which occur are caused by illuminating gas leaks, and that furthermore, although the separators cost from $500 to $1,000 each, they are not efficient in overcoming the evil, if it does exist.

Mayor Mitchel, basing his ideas on the report of the fire department and contentions of the sewer employees, maintains that the ordinance must be carried out.

Detroit Police May Regulate Taxi Stands

DETROIT, MICH., Sept. 18—A new ordinance will be submitted to the city council next week, having already been adopted by the council committee on ordinances, and if finally passed will enable the police commissioner to decide where taxicab and automobile stands may and may not be located.

The commissioner thinks that property owners have no right to receive compensation from automobile or taxicab owners and it has been shown that many derive a large revenue therefrom. It is claimed that one downtown property owner has been receiving about $1,500 a year from the renting of space in front of his property in a leading thoroughfare.

Another ordinance will be submitted regulating the rates to be charged for motor cars rented by the hour. The maximum fare is to be $3.00 an hour for a five-passenger car and $4.00 per hour for car seating more people.

Standard Not Guilty of Monopoly

NEW YORK CITY, Sept. 21—The Standard Oil Co. has not violated the Seven Sisters act passed in the State of New Jersey while President Wilson was governor and tending to check monopoly. The Crew-Levick Co., Jersey City, an independent, charged that the Standard was charging a low rate where there was competition and a high rate where there was none. The court, in arriving at its decision, took into consideration the competition of the Gulf Refining Co., which has been engaged in a not entirely one-sided price war with the Standard company and has taken some of the latter's customers.

Lozier Co. Charged with Insolvency

DETROIT, MICH., Sept. 20—Lee E. Joslyn, referee in bankruptcy, was to-day appointed custodian of the property of the Lozier Motor Co. by U. S. District Court Judge Tuttle, pending the hearing to take place next Wednesday, when it will be decided if the company should be declared bankrupt or placed in the hands of a receiver.

An involuntary petition was filed by three parts makers. According to the Lozier company's attorney, the company does not admit itself insolvent. According to a statement of the company's standing in December, 1913, the total assets then amounted to $4,067,051 and the total liabilities to $1,572,667.

The capital stock of the company consists of $2,500,000 in common and $500,000 preferred 7 per cent.

Cotton Traded for Cars in Georgia

ATLANTA, GA., Sept. 18—Confident that business conditions in the country are improving steadily and that the future demand for cotton will be exceptionally heavy and that consequently there will be big sales, the Forsythe Motor Co., of this City, distributor of the Stearns-Knight cars, will accept cotton in payment for automobiles. The company has been running the following advertisement in a local paper:

Forsythe Motor Co., distributor of Stearns-Knight cars, will accept properly certified warehouse receipts for cotton, upon a basis of not less than 10 cents a pound, middling cotton, in settlement for automobiles.

This cotton will be held until February 1, 1915, and if at that time it can be sold for more than 10 cents a pound the original owner will receive the increase, less the cost for holding.

If the cotton does not sell for as much as 10 cents a pound we will bear the loss.

We offer the following cars for immediate delivery: Five-passenger National, seven-passenger Fiat limousine, five-passenger Stearns-Knight, four-passenger Stearns-Knight, Pope-Toledo raceabout, Babcock electric, seven-passenger Cole.

Nebraska Wheat, 142 Per Cent. of Average

OMAHA, NEB., Sept. 20—The United States National Bank of Omaha has just compiled its annual estimate of the size and value of the crops raised this year within the boundaries of Nebraska. These figures were taken in conjunction with the reports of the agricultural departments of the United States and Nebraska.

The figures show that the wheat crop that has already been housed is 142 per cent. of the five-year average and is 69,735,000 bushels. The advance in prices, due to the European war, gives an added value of $35,000,000 to the wheat alone.

The big corn crop, although only 82 per cent. of a five-year average, is still more than 150,000,000 bushels, and the war prices have advanced the value of this crop something like $30,000,000. Then the demand for oats, alfalfa, hay etc., for the horses of the armies of Europe has sent prices away up above normal and has added a number of millions of dollars to the Nebraska farmers' bank account.

Hudson's August Shipment 1,697 Cars

DETROIT, MICH., Sept. 21—During August, 1914, the Hudson Motor Car Co., has shipped 1,697 Hudson cars, or 897 more than during August, 1913. During the first two weeks of September of this year shipments totalled 1,250 cars or five times as many as during the corresponding period of 1913. Everything indicates a continued increased activity at the Hudson plant and by October 1, it is planned to have between 2,700 and 3,000 cars shipped.

CHICAGO, ILL., Sept. 21—J. F. Reddick, formerly a director of publicity with the Goodyear Tire & Rubber Co., Akron, O., has been appointed advertising manager of the Stromberg Motor Devices Co., of this city.

Marmon on High Goes 355 Miles in New England

BOSTON, MASS., Sept. 19—Frank E. Wing, New England, distributor of Marmon cars, made a new touring record in the demonstrator of the 1915 medium six this week. He drove

Market Reports for the Week

No important changes occurred in this week's market reports. Tin has a fluctuating week, its highest quotation being at $32.00 and its closing price at $31.65, at a gain of $0.40 per 100 pounds. Copper exports have been normal. Last week exports of coper from New York City and Baltimore aggregated 1,737 tons. Since the first of September total exports from Atlantic ports have amounted to 11,897 tons. Lead is quiet and barely steady. A reduction was announced in Kansas petroleum from $0.65 to $0.55 per barrel.

the car from Boston through to Bretton Woods, up over Tug-of-War hill in Crawford Notch, and then down to Boston again through the other route via Merrimac Valley, a distance of 355 miles, with the gear speed shift lever sealed in high gear. It was the first time any car has ever attempted the feat. The car carried four people, and was not prepared especially for the trip. The party left Boston at 5.20 a. m., Wednesday and reached Bretton Woods at 11 p. m., starting back at 12.30 reaching Boston at 7.15. With the time taken out for breakfast at Portsmouth, filling with gasoline at Rochester and Franklin and the time spent at Bretton Woods, the actual time was about 11 hours. Tug-of-War hill in Crawford Notch is the famous hill that broke the hopes of a lot of contestants, in the early Glidden tours, who had to be towed up.

On the Glidden tours the trips to Bretton Woods from Boston was divided into 4 days, 2 up and 2 down, with night stops at Portsmouth and Concord, half way cities, but Mr. Wing did it in a daylight to dusk trip, and had he wanted to speed could have made it in 10 hours. He averaged about 11 miles to the gallon of gasoline.

2-Cent Postal Rate Suggested for S. A.

WASHINGTON, D. C., Sept. 21—The Post Office Department is actively co-operating to stimulate trade between the United States and South and Central America. Postmaster-General Burleson has under consideration a plan making the 2-cent rate for letter postage effective throughout the Western Hemisphere. Today he issued an order directing the Third Assistant Postmaster-General to suggest immediately to the representatives of the Latin-American countries, with which the United States does not now transact money order business, the desirability of concluding conventions for that purpose. These countries are Argentina, Brazil, Columbia, Dutch Guiana, Paraguay and Venezuela, in South America and Guatemala, Nicaragua and Panama in Central America.

E. V. A. A. Completes Convention Program

NEW YORK CITY, Sept. 21—The program of the Fifth Annual Convention of the Electric Vehicle Assn. of America, which will be held on October 19, 20 and 21 at the Hotel Bellevue-Stratford, Philadelphia, Pa., is complete.

Some of the articles that will be read at the convention are as follows: October 19, afternoon, "Progress of the Electric Vehicle," by J. H. McGraw; "Electric Vehicles in Parcel Post Service," by W. P. Kennedy; in the evening, F. Nelson Carle will speak on "Special Applications of Electric Trucks; October 20, morning, "Electric Vehicle Performance," R. B. Grove; October 20, afternoon: "Electric Fire Apparatus," Chief G. S. Walker; October 21, morning: "The Design and Performance of Electric Vehicle Motors," H. S. Baldwin; and October 21, evening, "European Development of the Electric Vehicle Industry," P. D. Wagoner.

Regular Vacuum Oil Dividend

NEW YORK CITY, Sept. 22.—The Vacuum Oil Co. has declared the regular semi-annual dividend of 3 per cent., payable October 31, to stock of record October 15.

NEW YORK CITY, Sept. 19—The Willys-Overland Co. declared a regular quarterly dividend of 1 3-4 per cent. preferred, payable October 1, to stock of record of September 22.

HARTFORD, CONN., Sept. 20.—The Colonial Auto Co., Studebaker distributor, has adopted the 50-hour-free service plan. All purchasers of 1915 Studebakers will be given coupon books representing 50 hours of free service. The plan originated with Russell P. Taber, the Reo distributor.

Sphinx Small Car for $695

NEW YORK CITY, Sept. 22—The Sphinx Motor Car Co., York, Pa., has announced a five-passenger touring car selling for $695 with standard equipment, including an electric generator and starter, electric lights, windshield, and spare rim. Wire wheels will be put on for $25 extra.

This new car has a 112-inch wheelbase and a tread of 54 1-2 inches, with a four-cylinder monobloc motor, delivering 28 horsepower. This motor has enclosed valves, detachable head and a camshaft with integral cams. The bore is 3 3-8 inches and the stroke 5 inches. It is claimed that the car will give 25 miles to the gallon of gasoline, and for oil, 250 miles per quart.

Cantilever springs, both front and rear, are used. Thermo-syphon cooling, shaft drive and a streamline body are features.

Operations were started this week in the large three-story brick factory building, North Duke street and the Pennsylvania railroad, formerly occupied by the Hart-Kraft Motor Car Co.

A Child's Seat for Saxon's

DETROIT, MICH., Sept. 18—A novel seating arrangement has been provided by the Saxon Motor Co., which gives accommodation in the Saxon light car for a child in addition to two adult persons.

The child's seat is an additional equipment to the new cars and is placed near the dashboard and fronts the two adult seats. It is neat and compact and when not in use may be closed. It does not interfere with either of the other passengers. It is provided at a cost of $10.

Allen Co. Elects; To Build 2,000 Cars

FINDLAY, O., Sept. 19.—The Allen Motor Co., Fostoria, O., has had its annual election of officers, resulting as follows: President, E. W. Allen; vice-president, Gratton Baker; second vice-president, J. E. Wright; third vice-president, P. J. Cristy; treasurer and general manager, W. O. Allen; secretary, A. E. Wyant; general superintendent, L. A. Summers. The company's business the past year amounted to $800,000, and it will complete 2,000 cars this year.

Purchases Cotton for Automobile Dealers

TOLEDO, O., Sept. 21—John N. Willys, president of the Willys-Overland Co. has purchased a bale of cotton for each of the 400 Overland dealers in the South. Mr. Willys says that it is his intention to buy an additional bale of cotton for each Overland car purchased during the 2 months ending November 17.

BOSTON, MASS., Sept. 23—A meeting of stockholders of the Walpole Tire & Rubber Co. has been called for September 29, when it is understood directors will signify their intention of serving in that capacity if the company is reorganized and taken out of the hands of receivers.

New Pullman for $695

YORK, PA., Sept. 22—Announcement was made this week by the Pullman Motor Car Co. of a new model, to sell at $695. It is almost identical in design with the Light Six 6-48 with refinement details, only much smaller. The car has a four-cylinder engine capable of developing about 30 horsepower, one man top, cantilever springs, demountable rims, electric lights and electric starter. It is the plan to build the new model in a touring car and roadster. Deliveries of the new car will begin to be made in limited quantities about November 1.

NEW YORK CITY, Sept. 21—H. W. Hayden, general manager of the Pullman Motor Car Co., announces he has completed arrangements with the Drouet & Page Co., Inc., to represent the Pullman in the New York territory, including northern New Jersey, Greater New York, Westchester, Putnam and Orange counties.

1915 Paterson Complete, $1,485

FLINT, MICH., Sept. 14—The W. A. Paterson Co., announces that the price of its 1915 six-cylinder car is $1,485, completely equipped. The motor is a Northway cast in block with 3 1-2-inch bore, 5-inch stroke, having L-head valves. The carbureter is a Stromberg and the Delco starter, lighting system and magneto is used. The wheelbase is 124 inches and the wood wheels are fitted with 34 by 4-inch tires, both on the front and rear. The car will be equipped with left drive and center control. The axles are Weston-Mott, floating. The equipment will be standard and includes a motor driven air pump.

Since the announcement last week of the new four-cylinder Paterson the company has decided that it will build these cars with a floating rear axle instead of a semi-floating and that a Stromberg carbureter will be used.

Hearing Against Pope Co. Oct. 1

HARTFORD, CONN., Sept. 20.—Richard J. Goodman, a committee of the superior court, is to hear the claims presented against the Pope Manufacturing Co. and has made the following assignment of claims hearings: Thursday, October 1, Hancock Mfg. Co. and the Mogul Co.; Monday, October 5, Edwin J. Blake; Monday, October 12, the claims of Albert L. Pope; C. E. Walker and W. C. Walker.

Annual Outing of Big Village Boost Game—Five Motor Car Con

NEW YORK CITY, Sept. 19—Following the custom established several years ago, that portion of the New York City automobile trade which goes to make up the organization known as the Big Village Motor Boosters, held its annual outing at Fred. Wagner's Long Island farm at Smithtown today. Nearly 200 dealers and their guests assembled. They were conveyed to the picnic ground in 43 automobiles.

Automobile Events Prominent

The program for the day was a lengthy one and in contradistinction to other programs of a similar kind, contained a fair proportion of events which required the use of automobiles. Of the fifteen contests which were decided, five were for motor car drivers. These were as follows: Forward and reverse race in which the driver was required to drive forward about 50 feet, reverse and drive backwards to the finish line; speed guessing contest, in which the speedometer was covered and the driver was required to cover a specified distance in a secret time; gymkhana race in which the driver drove to station 1, removed his coat and lighted a cigar, drove to station 2 and uncorked and drank a bottle of liquid refreshment, drove to station 3 and signed his name, put his coat on and buttoned it and drove to station 4, the finish; potato race in which a companion to the driver dropped six potatoes into as many baskets, the one having the greatest number of potatoes in the basket and completing the race in the shortest time to win; slow speed on high gear race.

N. Y. Dealers Win Baseball Game

Between these various automobile contests there were 10 athletic events and a baseball game between a team of New York dealers and a team of Brooklyn dealers. The New York men won, the final score being 10 to 1. Following the athletic program, a clam-bake brought the day to a close.

The summary:

Wheelbarrow race: First heat won by C. Smith and G. Sullivan; second heat, E. G. Baker and Isacson; third heat, S. Marks and Arthur Haines; fourth heat, D. Beecroft and N. Lazarnick. Final won by S. Marks and Arthur Haines.

Fat man's race, 50 yards—Won by M. A. Noonan; second, F. G. Hill; third, J. Kirk. Time 5 sec.

Three-legged race—First heat won by E. D. Studebaker and J. S. Bestar; second heat, J. Brietenbach and G. Arbogast; third heat, M. W. Colwell and E. H. Burgin. Final, J. Brietenbach and G. Arbogast; second, E. D. Studebaker and J. S. Bestar.

Fifty-yard dash—Won by E. D. Studebaker; second, G. Arbogast. Time, 5 1-5 sec.

Sack race, 50 yards—Won by Gene Sullivan; second, G. Arbogast. Time 12 2-5 sec.

Automobile Sports Hotly Contested

Forward and reverse automobile race—Won by A. Hartog (Packard) 15 2-5; second, H. B. Mall (National), 16 2-5; third, Geo. B. McCutcheon (National coupé), 17 sec.; fourth, J. Brietenbach (Chandler), 17 4-5; fifth, M. E. Le Bon (Jeffery) 20 1-5.

Secret time contest—Won by H. B. Mall (National), time, 22 sec.; second, A. Hartog, (Packard), time 21 4-5 sec.; third, R. H. Johnston (White), time, 23 3-4 sec. Secret time, 22 sec.

Gymkhana race—Won by Fred. Miller (Packard), time, 1:26 4-5; second, tie, W. C. Poertner (National), and H. B. Mall (National), time, 1:24 4-5; third, D. Beecroft, (White), time, 1:45 3-5.

Shoe race—Won by E. C. Blake; second, D. Beecroft.

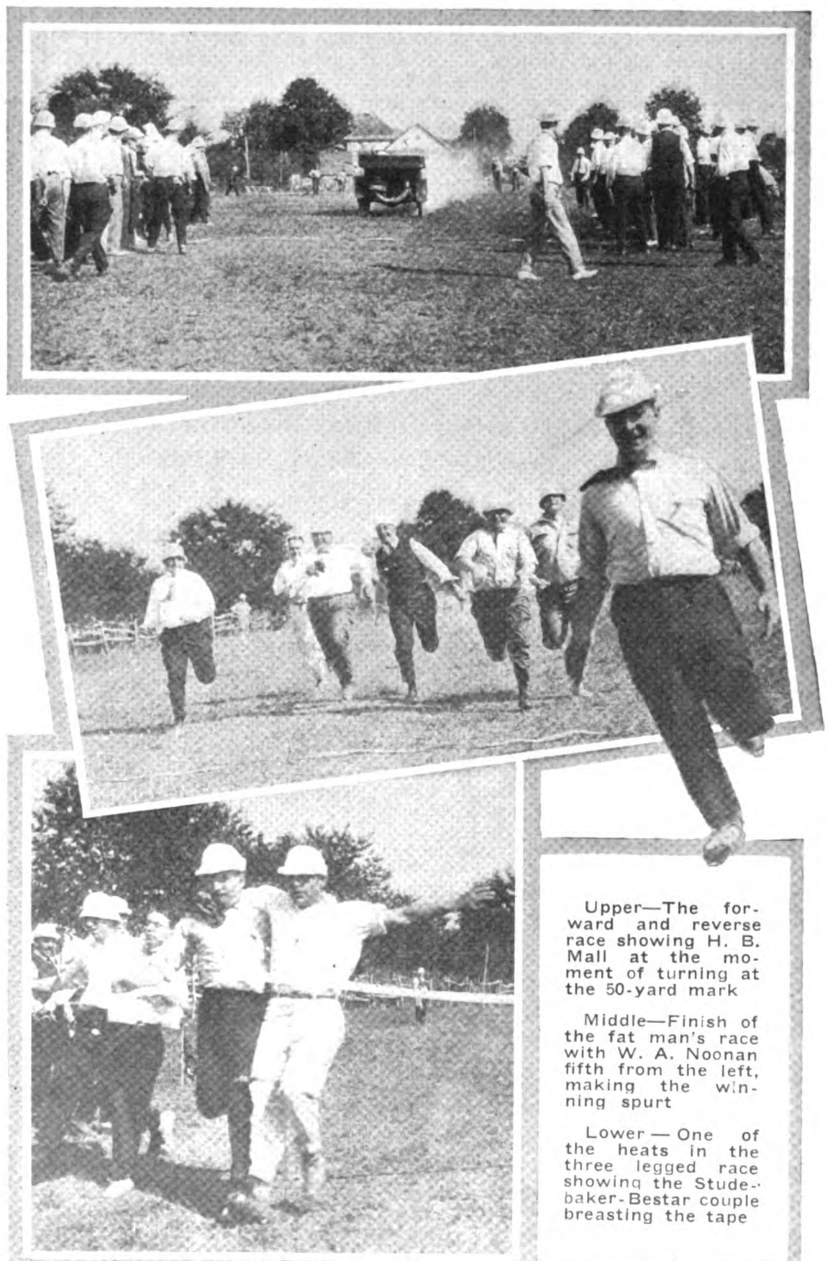
Slow speed on high gear—Won by Chas. A. Hopfensack (Chandler), 23 2-5 sec.; second, E. C. Blake (Packard), 20 3-5 sec.; third, R. H. Johnston (White), 20 1-5.

Geo. Robertson Cup—Won by W. Parkinson.

Poertner Wins Potato Race

Potato race—Won by W. C. Poertner, driving a Jeffery and with Roebensteik as bomb thrower, won, his time being 14 4-5 seconds, with 5 potatoes in the baskets.

Throughout the whole of the program good fellowship prevailed. The staging of the Booster's outing was placed in the hands of a number of committees, who gave freely of their time that the event might be a success. The commissary department was under the direction of H. A. Bonnell.



Upper—The forward and reverse race showing H. B. Mall at the moment of turning at the 50-yard mark

Middle—Finish of the fat man's race with W. A. Noonan fifth from the left, making the winning spurt

Lower — One of the heats in the three legged race showing the Studebaker-Bestar couple breasting the tape

Burman and Oldfield Smash Mile Track Records

ST. LOUIS, MO., Sept. 20—Barney Oldfield, driving a Fiat Cyclone on the Maxwellton mile track in this city, today broke two existing records when he covered the mile in 44 seconds flat, and drove 5 miles in 3:40 2-5. The previous existing mile record of 46:40 was made by Oldfield in a Christie at Bakersfield, Cal., August 27 last year.

The previous 5-mile record was held by Louis Disbrow in a Simplex and was 4:06:58, made at Cleveland, September 14, 1912.

Oldfield's new records were made today at the postponed Labor Day meet of the St. Louis Automobile Racing Assn., which has promoted several track meets during the season. The Maxwellton track can scarcely be considered a conventional 1-mile dirt track in that it is more nearly circular than the ordinary track. Its curves have a radius of 675 feet, whereas the ordinary radius of the mile track is 400 feet. The curves are banked to 8 1-2 degrees. Timing was done by the Stewart Indianapolis timer, which was leased for the occasion. It will remain for the Contest Board at the American Automobile Assn. whether Oldfield's two records will be allowed, but it would seem that there should not be any reason why they should not. The meet was under the direction of W. P. N. Stevens, Contest Board representative from Kansas City, Mo., who is entirely familiar with track contests.

SPRINGFIELD, ILL., Sept. 19—Burman made mile dirt-track records today at the Illinois State Fair, when he traveled 20 miles in 17:10 3-5 and 25 miles in 21:17 3-5. These records for a circular track were formerly held by Louis Disbrow, who made 20 miles in 17:57 at San José, Cal., and by Barnes, who did 25 miles in 22:07 at Portland, Ore.

$7,000 Prizes at Oklahoma Fair Races

OKLAHOMA CITY, OKLA., Sept. 19—With $7,000 in prize money, Oklahoma City offers a program of dirt track automobile racing at the state fair beginning Sept. 19 and ending Oct. 3, with Louis Disbrow, Heine Ulbricht, Fred Horey, Johnny Raimey, Joe Cleary, former Texas Ranger, "Mad Lou" Heineman and Eddie Hearne scheduled to start.

Elkhart Parades at Lincoln Highway Dedication

INDIANAPOLIS, IND., Sept. 21—A section of the Lincoln Highway, which has just been improved, was formally dedicated at Elkhart last Wednesday. This is five-eighths of a mile long and is the first section in Indiana to be completed. As a part of the program, there was a parade of 286 motor cars over the pavement.

Studebaker's Sales Triple in 2 Weeks of September

DETROIT, MICH., Sept. 21—As an evidence of national prosperity the Studebaker Corp., has made public the record of the actual sales made by its 13 branches in the country during the first 2 weeks of this month. The result shows sales aggregating $1,118,447 as against a total of $373,411 for the corresponding 2 weeks in 1913. There is thus a gain this year of $745,066, and the total increase of business is 300 per cent.

The sales made by each branch during the first 2 weeks of September this year and last year were as follows:

Branch	1914	1913
Chicago, Ill.	$ 278,433	$ 73,570
Minneapolis, Minn	148,464	55,825
Kansas City, Mo.	139,386	26,554
Philadelphia, Pa.	76,761	12,735
Omaha, Neb.	69,306	14,463
Boston, Mass.	67,553	25,685
Dallas, Texas	56,901	16,269
Atlanta, Ga.	51,168	11,882
St. Louis, Mo.	50,505	46,073
New York, N. Y.	46,018	25,344
San Francisco, Cal	45,571	30,776
Portland, Ore.	45,071	13,354
Detroit, Mich.	43,340	20,381
Total	$1,118,447	$373,411

While these figures show the results of only one manufacturer, they give a fair idea of the business conditions in certain parts of the country. Thus it will be seen at once that it seems that in the Western States the demand for motor cars is much heavier than in the East.

One Six—National Offering for 1915

(*Continued from page* 596)

travel has necessitated lengthening the shaft .25 inch.

On the stock cars the wheels are wood although wire-wheel equipment will be fitted at an additional cost of $125. The tires are 36 by 4.5. The drive is taken through the main leaf of the rear spring and is heavily constructed for that purpose. Easy riding is insured by a comparatively large number of thin leaves. There are eight leaves in the cantilever. The springs are linked at the forward end and swivelled at the center; that is, the fixed point of the spring is at its center and the play is given at the extremities. The tensile strength of the steel used is 120,000 pounds to the square inch. The spring measures 53 inches over all.

VOL. XXXI NEW YORK—THURSDAY, OCTOBER 1, 1914—CHICAGO No. 14

The AUTOMOBILE

Tax Gasoline—Tax Coal, Oats

Gasoline Tax To Yield $12,000,000 Annually—Horse Tax Would Yield $365,000,000

If One Fuel Is Taxed All Should Be

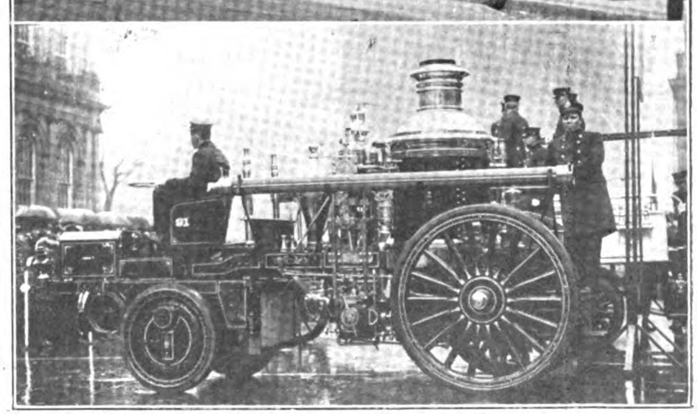
By J. Edward Schipper

Horse carriage not taxed; taxicab may pay

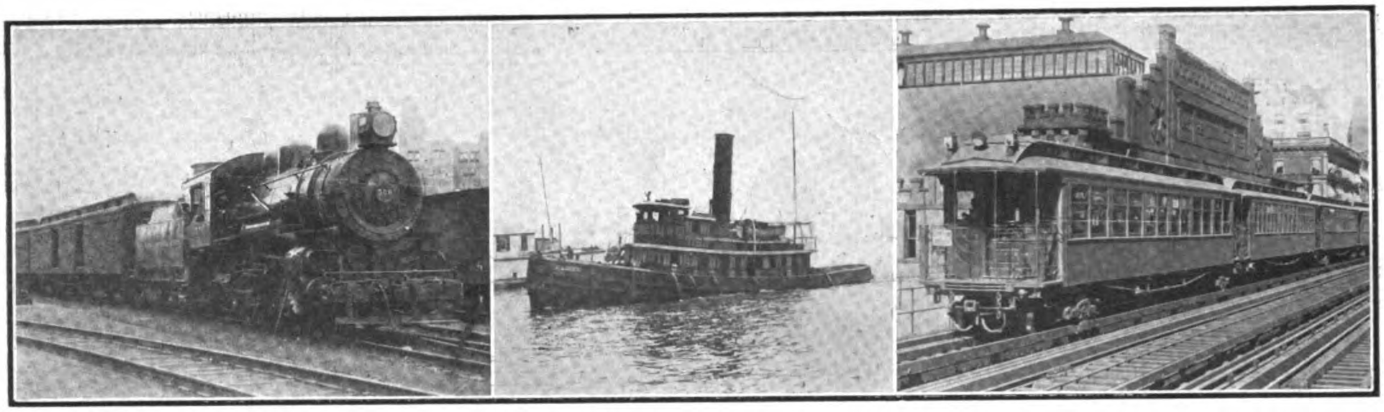
OUR Government wants to raise $12,000,000 through a tax of 2 cents per gallon on gasoline. If the food for horses were taxed on the same proportion it would amount to $1,000,000 per day or $365,000,000 per year.

Statistical reports from the Department of Agriculture give the ratio of horses to peopie in the United States as .21 to 1. There are now more than 90,000,000 people in this country and hence more than 18,000,000 horses. Regarding food as the fuel of the horse, each animal uses 65 cents worth a day, or approximately the equivalent in money value of 4 gallons of gasoline. At this rate if an equal tax were made each horse would be taxed 8 cents a day and the yield to the Government would be more than $1,000,000 per day, or $365,000,000 per year.

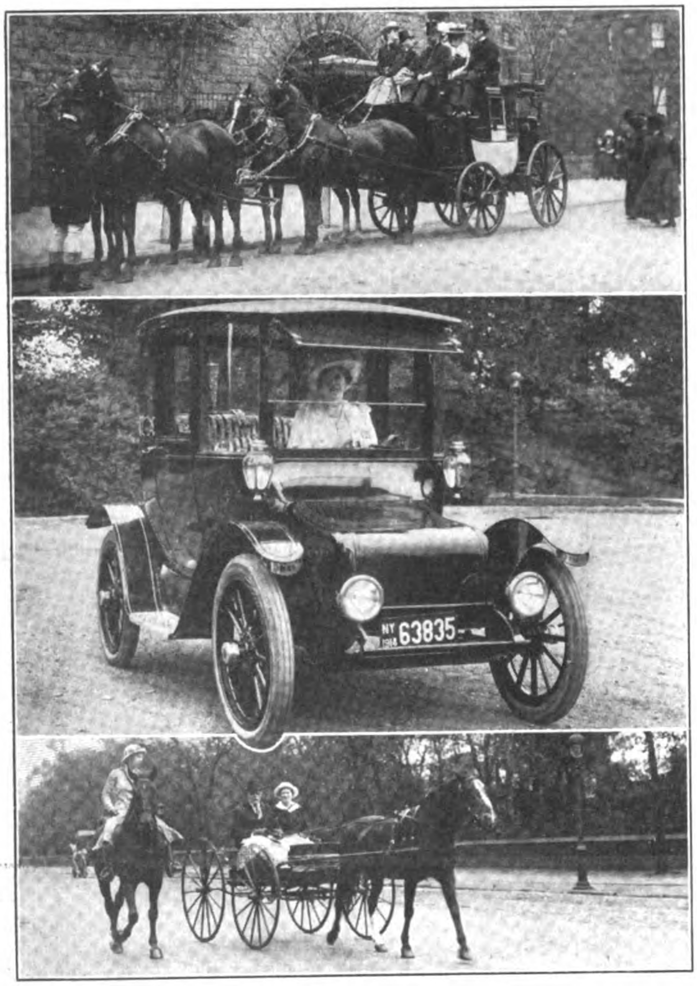
Because the automobile is economical and does not use the same amount of food or fuel as the horse a tax rate is put upon it that would be out of all proportion to that which would be applied to horses even were they taxed. The Government would not expect a yield of $1,000,000 a day or $365,000,000 a year from horses. But if an automobile used the same amount of fuel as a horse, that is the rate at which the proposed tax would work out. Regarded in this light it is nothing more than a tax on economy.



While the horse fire engine is slower, it is not taxed; the motor fire apparatus might pay a duty



Three classes of vehicles that would not suffer under the proposed legislation, locomotive, towing vessel and elevated train



Luxurious methods of travel that would pass untaxed

The proposed tax on gasoline will double the cost of motoring so far as taxation is concerned. To explain: In the State of New York a man owning a 30-horsepower touring car pays an annual registration fee of $10. If he travels 7,500 miles and averages 15 miles to the gallon he will use 500 gallons of gasoline. At the proposed tax of 2 cents per gallon he will have handed the Government another ten dollar bill at the end of the touring season. His annual fees for the privilege of using his car are doubled, are $20 instead of $10.

The operator of a 3-ton truck who drives 10,000 miles in a year, will use approximately 2,000 gallons of gasoline. At 2 cents per gallon the tax will be $40 a year in addition to his $5 registration fee.

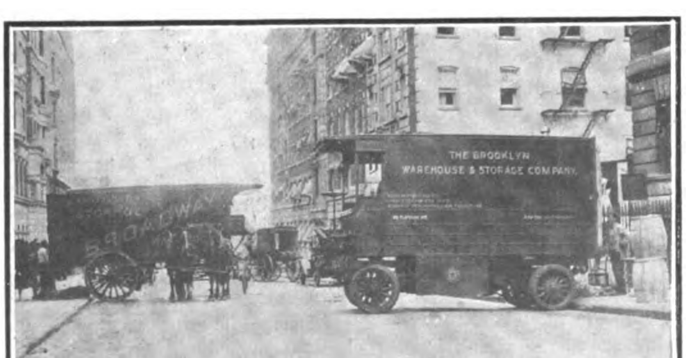
There are 1,500,000 motor vehicles now in use in the United States. The average vehicle travels 4,000 miles in a season. To be conservative it will travel 10 miles per gallon. In other words, it will use 400 gallons in a season, paying a tax according to the proposed rate of $8 per year.

NOT LESS THAN $12,000,000 WILL FIND ITS WAY FROM THE POCKET OF THE MOTOR-USING PUBLIC INTO THE HANDS OF THE STATE IN A SINGLE YEAR.

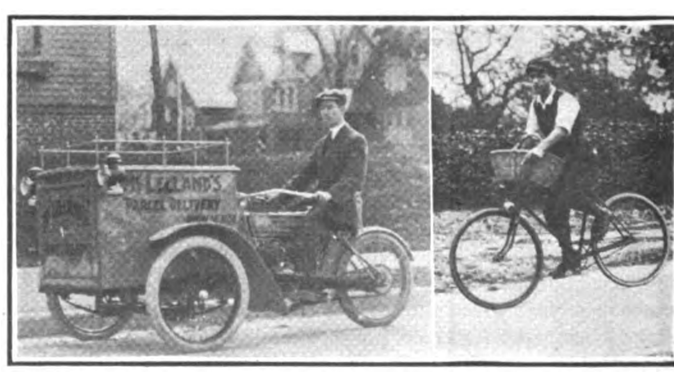
The American citizen is patriotic and is willing to stand behind the Government and meet the demands of taxation, when that taxation is just, without a murmur. The $12,000,000 which is drawn from the automobile user during the year would doubtless be paid without protest were it not for the seeming unfairness of a tax which recognizes one class and ignores another. The citizen who owns a fleet of motor-moving vans has to compete with another who owns a fleet of horse-drawn vehicles. The Government proposes to tax the progressive man who has displaced his horses by the more modern method and not to tax the one who employs the less efficient vehicle.

It should not be the purpose of those in authority to place a tax upon the factors of efficiency in any man's business.

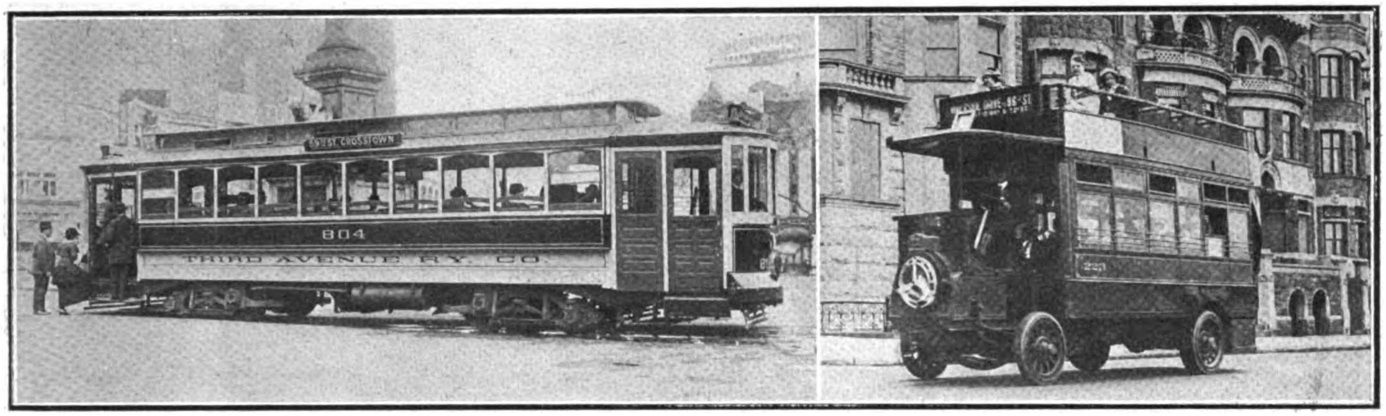
A lady stepping from her luxurious residence into her waiting electric is carried to the door of her jeweler, purchases a pair of ornamental and expensive earrrings and returns to



The gasoline van taxed, the electric untaxed



Delivery by motor vehicle would be taxed; by bicycle, not



The trolley does not pay a tax on its fuel, while the motor bus would if the new law went into effect

her home after a trip in which there has been no industrial good gained for the community, insofar as the method of propulsion of her vehicle is concerned. That is, had she taken a passenger bus the same effect would have been accomplished. Her trip has been an untaxed luxury. On the other hand a family moving its household effects from the city to the farm and employihg the gasoline truck has according to the reasoning to be inferred from the proposed tax committed an act which should net an income to the Government. One type of vehicle is taxed, the other is not.

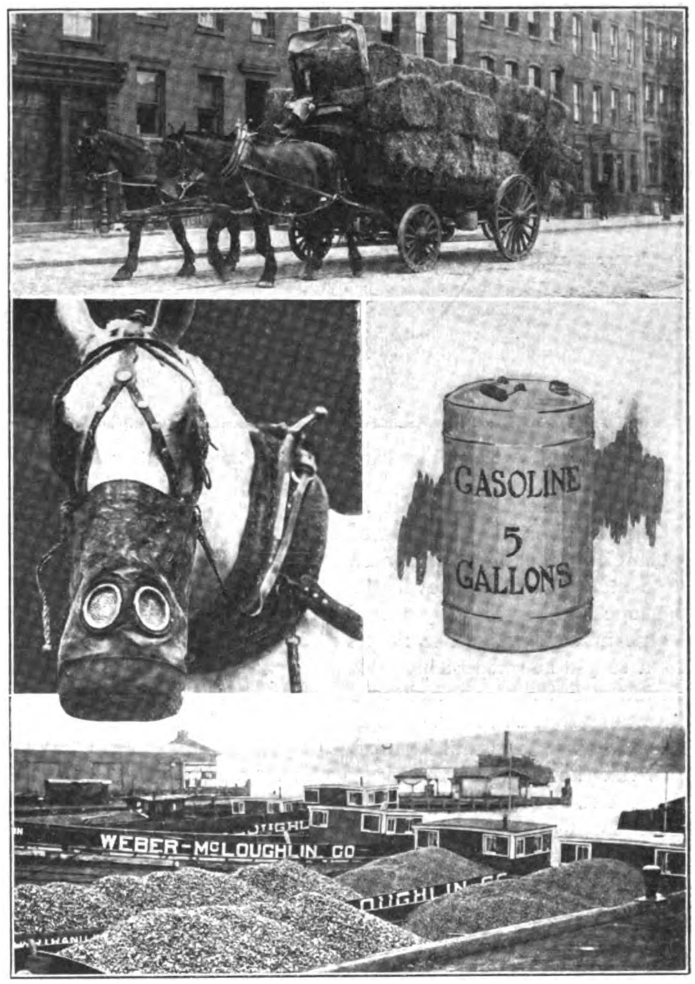
If the grocer delivers our groceries by gasoline truck he is taxed. If he employs a bicycle, an electric, or sends a boy on foot, he is not.

This analogy can be carried beyond the motor car industry. The fisherman, on the banks oi Newfoundland earning at great risk to himself and with small returns for his efforts an income from the sea, makes use of the motor dory. He uses gasoline for fuel and therefore should be taxed according to those who propose the suggested legislation. On the other hand the millionaire, who cruises about the sea in his palatial steam-yacht not seeking the treasurer of the ocean for profit or as a means of eking out his existence, is not taxed.

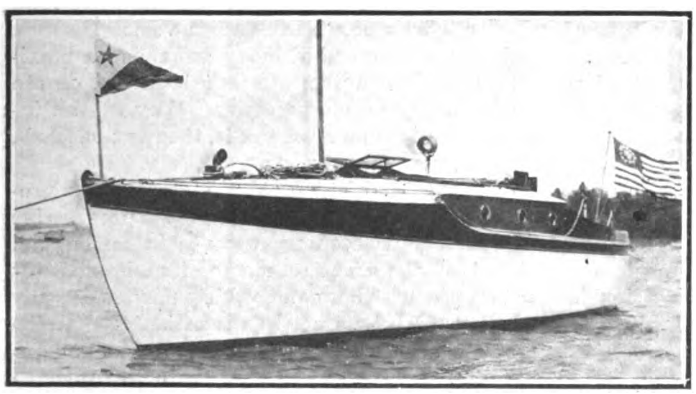
Tax One, Tax All

IF WE TAX GASOLINE, TAX COAL, WOOD, COKE, CRUDE OIL OR PRODUCER GAS.

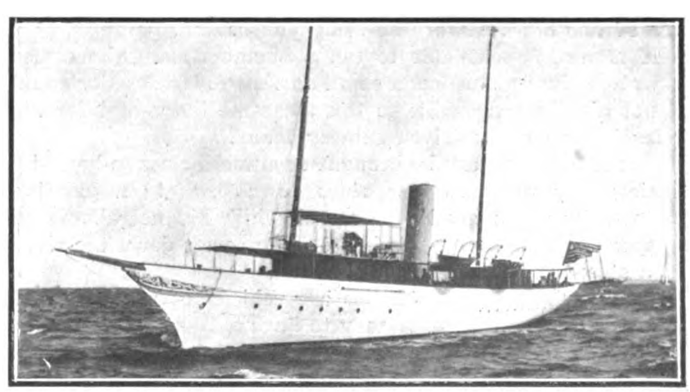
There can be no explanation why these fuels are not taxed, unless it is they are not used to propel automobiles. When the automobile originated it was the sport of the wealthy. The idea was engendered in the minds of those who witnessed the industry in its early stages that the owner of a motor car was of necessity a person of wealth. That idea is the seed which has created the growth of the idea which has now borne fruit in the proposal of a tax on the prime necessity of the automobile user. The horse is to the horse-drawn vehicle what the motor is to the motor-driven vehicle. Potentially, both are engines. Both need fuel. What the gasoline is to the motor, oats and hay are to the horse. Yet our government



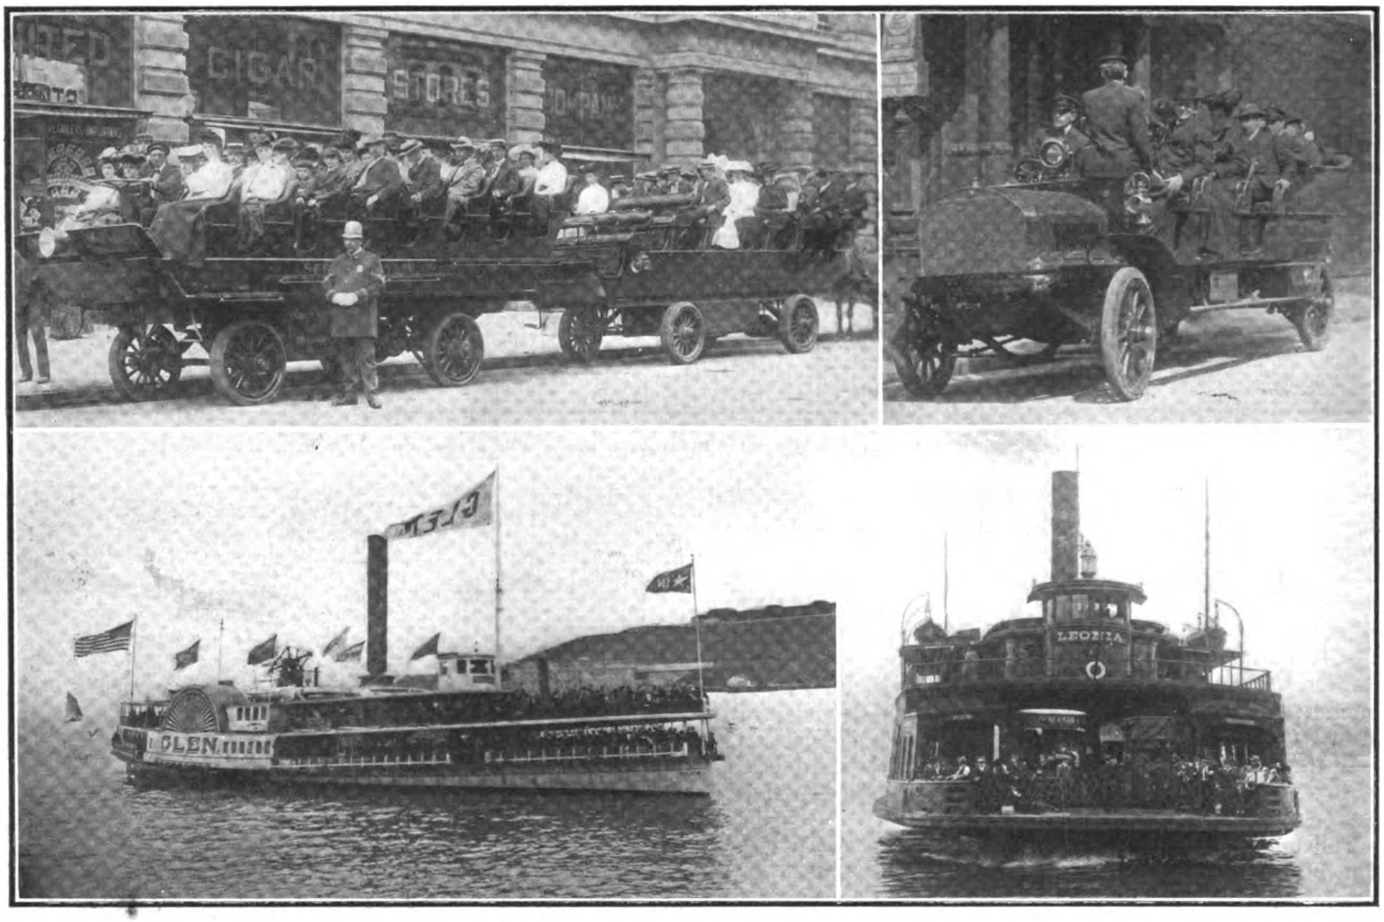
Hay, oats and coal are fuels that would not have to pay. A 5-gallon can of gasoline would net the government 10 cents



Gasoline launch would pay a duty of 2 cents per gallon



Steam yachts use coal and would not be taxed



Electric sight-seeing buses would not be taxed while gasoline ones would. Excursion boats and ferryboats would be on the free list

would tax the gasoline but not the oats, hay or other fuels.

There can be no intention of an attempt to drive the transportation plan of industry back to the wasteful quadruped. The motor car has proved its service to the governments of Europe and our country does not fail to recognize its immense value in times of peace as well as war. Gasoline has risen at a single bound to a position as a war-time necessity equal in importance to railroads and horses. Yet it is the only war necessity that is taxed. The question can be justifiedly asked, if we can tax one munition of war why not tax others? Why not tax the food for the mules when we are taxing the food for the motors? Both do the same work.

If the Government desires to raise $12,000,000 per year on fuels and then spread this tax over all the industrial fuels that are used, it would be found that the motorist would bear but a small percentage of the total. In our large cities, where millions are carried daily from their homes to their daily tasks, electricity plays the most important part in the transportation total. If it seems fair to tax the moving of household goods when they are moved by gasoline, would it not be also fair to tax the same people when they are making use of another fuel for the same purpose?

If it seems reasonable to tax a business man who comes downtown in a motor bus a small amount for each ride, would it not also be reasonable to tax the same individual for his rides in an electric-driven subway train?

The comparison can be brought even more close to home by asking why the man who rides down town in a gasoline motor-driven bus should be taxed while his neighbor who happens to take an electric bus or who comes down the river in a steam yacht, is not.

The 1,500,000 motor vehicles are vehicles of necessity and not luxuries. If it is necessary to have a 20-hour train from Chicago to New York, if it is necessary to have express trains on our subways, if it is necessary to have express service on our elevated railroads; then, it is equally necessary to have our gasoline cars which will carry the business man from his suburban home to his office with the greatest comfort and the least expenditure of time.

The business man considers it an economic investment to travel with the comforts of the limited train and save 4 or 5 hours besides. It is an equally economic investment for the business man to use his motor vehicle every day.

If it is necessary to have our fast freights to carry merchandise it is equally necessary to have our motor trucks that can deliver similar merchandise from the hub of our metropolis to the fringe of suburbs within a zone of 50 or 75 miles.

IN THESE FIELDS THE GASOLINE TRUCK IS AS GREAT A NECESSITY AS THE FREIGHT LOCOMOTIVE.

Why tax gasoline and not coal, why tax a motor vehicle and not a railroad train?

We insist on the fastest train for mail service. Our trans-Atlantic steamers are paid to make high speeds while serving the Post Office. Between offices in our great cities motor trucks are allowed to travel with special traffic privileges to make the best possible time in carrying on the vast mail business of industry. Why do we tax such a vehicle?

The intensified business method of today demands the maximum of out-door life. The automobile has been one of the greatest factors in supplying his necessity. Why tax an instrument of health? But, if we must tax it, then tax baseball, horse racing, golf, boating, tennis, etc.

It is a tax on the essence of progress. It is a tax on progressiveness because it is used only by the most progressive in business. It is a tax on economy because in commercial lines economy has been the great reason for its adoption. It is a double taxation because the motor vehicle now has to pay a state tax and very often it is a triple taxation in that the state collects money, sometimes the city and now the government would also take its turn in gathering an added revenue from this necessity.

Europe Orders 1,000 More Trucks

Both Belligerents and Non-Combatant Nations Send Emissaries To Buy American Commercial Vehicles—Quick Delivery Wanted—Order of 1,000 Trucks 2 Weeks Ago Officially Confirmed

NEW YORK CITY, Sept. 30—That European countries are deeply concerned in purchasing motor trucks from America has been again demonstrated this week, when an emissary of a European country arrived in America with direct orders from his government to purchase 1,000 motor trucks for the earliest possible delivery. These are to be 2-, 3- and 5-ton types. This fact coupled with similar requirements announced 2 weeks ago of European countries needing 1,000 trucks gives direct evidence of the stimulating influences on American truck business of the present war. In addition to these two large requirements, there have been many smaller shipments within the last month aggregating 200 trucks, so that the grand total of American trucks needed today by European countries, several of which are not belligerents, is 2,200.

Demand Is for 2, 3 and 5 Ton Trucks

SOUTH BETHLEHEM, PA., Sept. 30—The fact that European countries had their emissaries in America to purchase 1,000 motor trucks, which was published in THE AUTOMOBILE 2 weeks ago, has now been officially confirmed by the Bethlehem Iron & Steel Co., South Bethlehem, Pa., which has become the purchasing department of these foreign governments not only for the motor trucks, trailers and wagons, but also for such army supplies as horseshoes, army blankets, horse blankets, medical supplies, etc.

Buyers Are Increasingly Active

These emissaries of foreign governments, after making their headquarters in New York, invaded South Bethlehem, where the normal purchasing department of the steel company was set aside, and the entire executive department, including the board of directors, became a purchasing department of the whole for these various products.

As stated 2 weeks ago, the demand is practically for 2-, 3- and 5-tontrucks, many with trailer arrangements. The most popular military truck ranges from 2- to 3.5-ton capacity, as this is closely allied with the subsidized European truck.

Quick delivery is wanted on the majority of the merchandise ordered, due to the coming winter and the general military operations in Europe. It is now known that 150 motor trucks have been shipped from ports on the North American Continent during the past 10 days, and buyers from other foreign governments have arrived within the past week.

C. of C. Protests 2-Cent Gasoline Tax

NEW YORK CITY, Sept. 30—The National Automobile Chamber of Commerce has sent out letters of protest to members of the United States Senate against the tax of 2 cents a gallon on gasoline, naphtha and other similar products obtained from crude, partially refined, or residuum oils and suitable for motor power, as provided in the war revenue bill that was passed in the House of Representatives.

The National Automobile Chamber of Commerce points out that this is an excessive tax of 15 to 20 per cent. on a necessity and not a luxury; that the great majority of automobiles today are bought and used by farmers and others of moderate means, and that the tax will fall upon the consumer and not the producer of gasoline.

T. R. Lippard, president of the Stewart Motor Corp., Buffalo, N. Y., states, "We are strongly opposed to the gasoline tax because it puts the burden on such a small percentage of the people. The taxation should be borne by the majority instead of the few. Less than 2 per cent. of the people own automobiles and they are big users of gasoline automobiles. They are at present heavily taxed by the states or their own municipalities."

James L. Geddes, president of the Kelly Springfield Motor Truck Co., Springfield, O., states, "I believe the proposed tax on gasoline unwarranted as gasoline cannot possibly be considered a luxury. It is just as much a necessity as coal or any other fuel."

Car Owners Protest Proposed Taxation

WASHINGTON, D. C., Sept. 30—*Special Telegram*—The Senate finance committee is holding daily sessions on the war emergency tax bill and Chairman Simmons hopes to report the bill to the Senate before the week end.

Now that the committee is talking of substituting for the gasoline tax a tax on automobiles, to be measured by horsepower, owners of motor cars are beginning to be heard from. Senators and House members are receiving letters warning them that the automobile is no longer a luxury, but a necessity.

Members are being reminded in these protests that to tax automobiles would mean taxing trucks and vehicles used by merchants and business houses, and that this would be a tax on business in another guise.

A hot blast on the automobile tax came today from a Western preacher, Rev. V. M. Elston, Griswold, Ia. He denounced the proposed tax on gasoline and also the proposed automobile tax. He said gasoline was used by farmers and others for power purposes and its use was by no means confined to automobiles. As for the automobile tax, he informed Senator Kenyon that automobiles had become a necessity, whereas a lot of benighted folk seemed to be laboring under the idea it was still a luxury.

New Peerless Four for $2,000—Six $2,250

CLEVELAND, O., Sept. 29—Announcement has just been made by the Peerless Motor Car Co., of a lighter line of four- and six-cylinder cars which will supplement the large 48-horsepower sixes the company has been building for several years. The new four and six are styled "all purpose cars" as they are intended to perform equally well in touring work as for city driving. The four is offered at $2,000 and the six at $2,250.

The Peerless company places special emphasis upon the fact that these new cars are of European design, having small bore, high speed engines, that of the four being 3 3-4 by 5 and of the six 3 1-2 by 5. The wheelbases are 113 and 121 inches, respectively.

The bodies are streamline and very handsome. The front seats are of the individual type, making it possible to pass between them to the rear compartment.

Spiral bevel gears are used in the rear axles of these Peerless models as well as in the larger cars of the line. Some of the other features are left drive and center control, gearset of three-speed type in unit with motor. Gray & Davis cranking and lighting in connection with a 60-ampere-hour storage battery, multiple-disk clutch, vacuum gasoline feed from rear tank and the regular form of Peerless platform rear springing.

The equipment includes one man top, rain vision windshield, demountable rims with one extra, Stewart speedometer, tire pump, electric horn, and tools.

Complete description of these new Peerless models will appear in an early issue.

Packard Shipments Increase 75 Per Cent.

NEW YORK CITY, Sept. 30—The Packard Motor Car Co., Detroit, Mich., has increased its shipments for the last 2 months 75 per cent. over the corresponding time last year.

Comparing the Six With the Eight

Six Is Simpler and Lighter—Two Carbureters Almost a Necessity on Eight—Little Difference in Running Between the Six and Eight

By S. I. Fekete
Hudson Motor Car Co.

DETROIT MICH.—Editor THE AUTOMOBILE:—The recent advent of the eight-cylinder motor in America strongly recalls the situation of a few years ago when the six-cylinder motor was at a similar stage of its development. Should two more cylinders added to a six produce as great an improvement as did the addition of two to the four-cylinder motor a few years ago, then there would be grounds for believing that American manufacturers would be called upon in the future to meet a popular demand for an eight-cylinder motor.

The ascendency of the six-cylinder motor over the four was not established until after several years of educational work to familiarize the buying public with such features as, the effect of overlapping power strokes, smoothness, silence, flexibility and perfect balance.

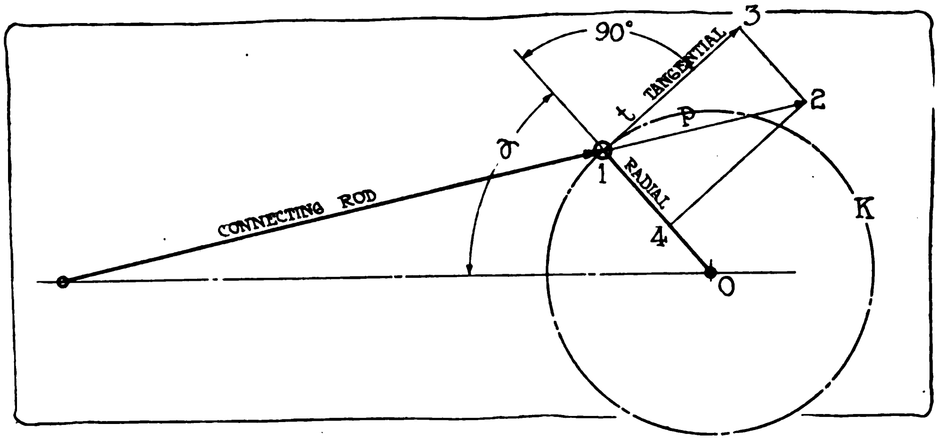


Fig. 1—To determine the magnitude of the tangential force when the crankpin is at any given angle from the center line of the cylinder. Line 1-3 is the tangential component and 1-4 the radial. It is first necessary to understand this tangential portion of the resultant force before considering what is to follow

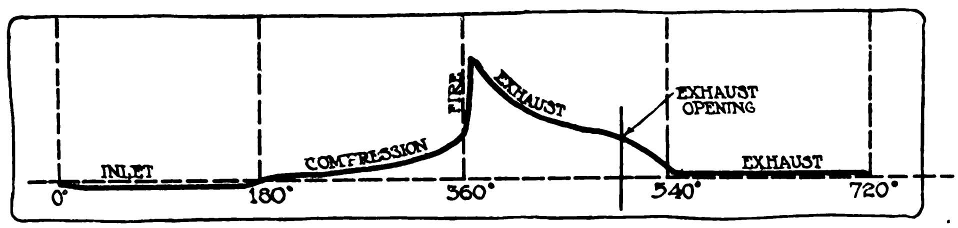

Fig. 2—The working forces acting in one cylinder for a complete cycle plotted on the 720 degrees of a cycle as a base and considering the pressures as ordinates. The pressure thus plotted may be taken from an indicator diagram. The first quarter, or 180 degrees, of the cycle is negative work on account of suction

Perfect Balance in Six

THE PUBLIC HAS THUS COME TO KNOW THAT NOT ONLY ARE THE VIBRATIONS DUE TO EXPLOSION PRESSURE, AND ACTION OF RECIPROCATING PARTS EQUALLY WELL BALANCED IN THE FOUR AND SIX, BUT ALSO THAT THE OCTAVE OR SYNCHRONIC VIBRATIONS OF THE FOUR ARE PERFECTLY BALANCED IN THE SIX.

The assimilation of these engineering principles would not have been alone sufficient to give the six its present dominance were it not for the fact that the six has in actual use adequately fulfilled claims which theory advanced in its favor.

The pioneer designers of six-cylinder motors based their designs upon extensive theoretical research in which they investigated by graphical means the advantages to be obtained by various cylinder numbers, groupings and firing orders.

The six-cylinder motors accomplished all that their engineers anticipated and eventually received the almost unanimous endorsement of that most skeptical and discriminating of critics—the buying public.

ANY MULTIPLE-CYLINDER MOTOR WHETHER OF TWO, FOUR, SIX OR EIGHT CYLINDERS IS THEREFORE NOT AN INVENTION BUT A DEVELOPMENT BASED UPON COMPARISON OF THE RELATIVE ADVANTAGES OF GROUPINGS OF CYLINDERS TO REMEDY CERTAIN DEFECTS, AND TO GAIN CERTAIN APPRECIABLE ADVANTAGES OVER A MOTOR OF FEWER CYLINDERS.

Six vs. Eight

So far as the overlapping power stroke in six-cylinder and eight-cylinder motors is concerned, it is true that the six does not get its second cylinder into action until later than the eight, but this in reality is fortunate because the second cylinder of the six comes into action at a point where the negative forces are at a maximum, whereas in the eight-cylinder motor the overlap comes in a place where the negative forces are at a minimum. This fact will be proven later in this article by means of diagrams.

Different from Aviation

The imitative tendency of human nature might lead the buying public to the conclusion that because multi-cylinder motors have been used to a large extent in aerial navigation they are equally desirable for automobile use. This impression is somewhat fallacious because the requirements of terrestrial and aerial transportation are essentially different. In aerial work gasoline economy is unessential and the important factors are safety and high power ranging from 80 to 200 horsepower. To both these factors the multi-cylinder motor is best adapted; to high power because by dividing a large piston displacement among several cylinders lower bearing pressure and stresses are obtained; to safety because with a motor of ten or twelve cylinders the misfiring of three or four cylinders does not imperil the iife of the aviator, while with a motor of four cylinders his only safety would lie in his ability to plane back to earth.

In the case of an automobile motor these two requirements are entirely absent, so that imitation of aerial methods provides hardly sufficient reasons for adoption.

The De Dion eight-cylinder motor is much heavier per unit of piston displacement than a six. When multiplicity of parts, intricate connecting-rod and magneto construction and complications in the lubricating and carbureter systems are considered, it would appear that manufacturing costs would be higher.

In this connection it is almost a necessity to use two carbureters to obtain efficient carburetion because of the fact that the manifolding and firing order is such that it is practically impossible to utilize the momentum of inflowing gas column on account of the action of the next cylinder which begins to take in gas when the preceding cylinder has reached only half of its travel.

Fours Are Out of Balance

In the case of a four-cylinder motor the octave vibration is synchronous and is therefore absolutely out of balance.

The six is perfectly balanced as regards octave vibrations.

The octave vibrations of the eight V-type are nearly in perfect balance and are in perfect balance in the eight all-in-line.

By octave vibration is meant vibration due to the non-infinite length of connecting-rod. That is to say when the piston is at half of its travel the connecting-rod is not yet quite 90 degrees on the crank circle from the vertical.

The present state of the art permits making six crankshafts in all respects the equal of eight throw cranks as regards vibration and deflection.

Reason for Diagrams

The surest way of finding out what results that a certain cylinder grouping will give is by a combined graphical representation of the functions of the cylinders not only as individuals, but also when acting simultaneously. The illustrations in this article are used for this purpose.

IF THE DIAGRAMS THUS PRODUCED SHOW HARMONY AND BALANCE BETWEEN POSITIVE AND NEGATIVE WORK, ONE CAN DERIVE FROM THEM INFORMATION WHICH WILL GUIDE IN DESIGNING A MOTOR TO GIVE DESIRED RESULTS.

The Vibration Pole

Inasmuch as the amount of vibration is the essential factor in comparing motor types, let us proceed to study this side of the subject.

If a well-balanced motor is running smoothly and we disconnect a spark plug it immediately becomes apparent from the sound that something is irregular.

To graphically duplicate the above conditions we may plot two tangential diagrams, the first representing all cylinders firing and the second representing one cylinder not. The first will represent the normal function of the motor and the second the impaired function. That is, the first diagram will consist of a series of undulations repeated at regular intervals while the second diagram will have similar undulations but at regular intervals one will be lacking and impair the harmony of the diagram.

The tangential diagram might therefore in popular parlance be termed the criterion of the motor, and from it we may derive conclusions as to the running qualities of the motor.

The obviously smoother running qualities of a six over a single-cylinder motor are accurately reflected in the tangential torque diagrams of the two, the curve variations in the six being small as compared to those of the single-cylinder because of the more uniform torque of the six.

Best Motor Defined

A motor which runs with the least injurious action of reciprocating parts and with the most uniform power acting constantly on the crankshaft is the best and smoothest running. A horizontal line is the graphical representation of such an ideal condition and it is approached only by certain types of electric motors. Such a line indicates no fluctuation.

The most complete information for exhaustive study of motor performance is offered by its tangential torque diagram and it clearly represents the working functions of the motor, both of reciprocating and rotating parts, including such items as:

Pressure variation during working stroke due to increase of gas volume.

a.—Acceleration of piston.

b.—Influence of acceleration and deceleration on the inlet, compression, working and exhaust strokes.

c.—Back pressure during exhaust stroke.

d.—Negative pressure in the inlet manifold.

e.—Character of pressures changes between crankpin and connecting-rod.

Not only are the above functions shown for each cylinder, but their simultaneous action in all the cylinders is revealed by this tangential torque diagram. *Therefore, if we have two motors of the same bore, stroke, compression, reciprocating and rotating part weights, the tangential diagram affords a fair and impartial means of comparing their performance.*

Need of Flywheel

Only motors, whose torque throughout each revolution is uniform, are capable of rotating with uniform angular velocity. Inasmuch as no existing gas motors possess constant magnitude of torque it is necessary to add a flywheel to approximate anywhere near uniform

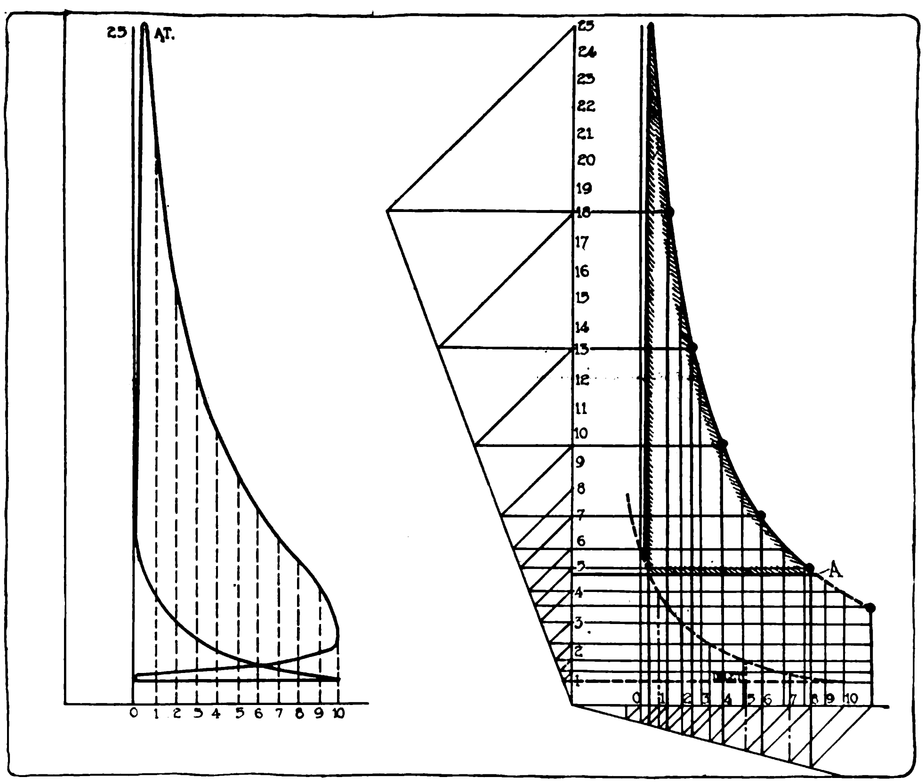

Fig. 3—Left—To take account of the pressure acting in a cylinder an indicator card is used. This shows positive and negative work, the only positive work being that done by the expansion of the gases after ignition. For later plotting purposes the base line has been divided into ten parts

Fig 4—Right—A theoretical work diagram for a single cycle. For purposes of comparing the negative work of different cylinder systems, the ignition pressure is considered to be 25 atmospheres. This merely serves to magnify the negative work and cannot be done except on a comparative basis. The only abnormal feature of the diagram is the exhaust line A; which is straight and at a height of 5 atmospheres. This corresponds to 75 pounds

Fig. 5—Left—Diagram of the inertia forces which act to oppose the motion of the masses; namely, piston, piston pin and upper end of connecting rod. These forces are neutral at middle of stroke and reach their maximum at top or bottom of the stroke. The diagram is plotted on one stroke as a base line

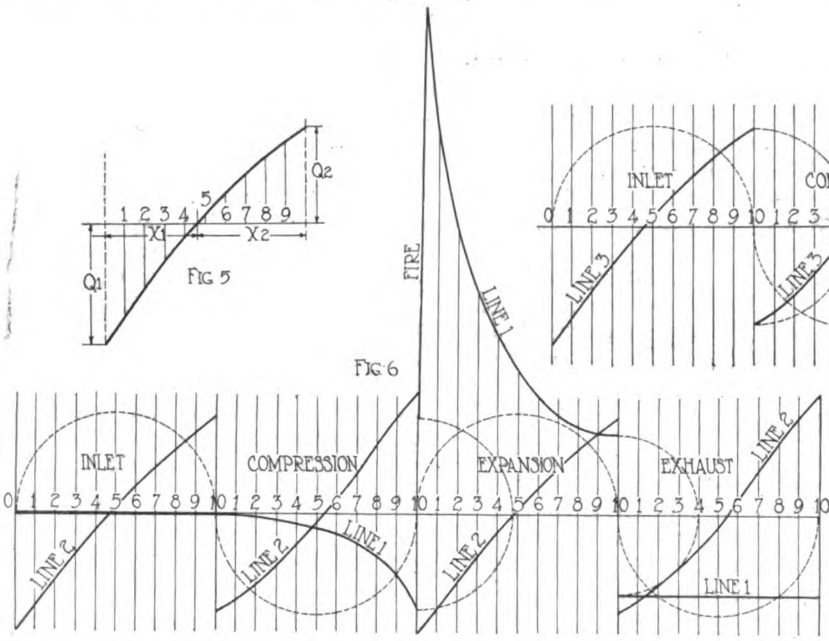

Fig. 6—Combining the inertia force of one cycle with the working forces acting due to the four steps of suction compression expansion and exhaust in a cycle. Line 1 shows the working pressure of Fig. 2 plotted to the same scale as the inertia forces, line 2, which are shown separately in Fig. 5

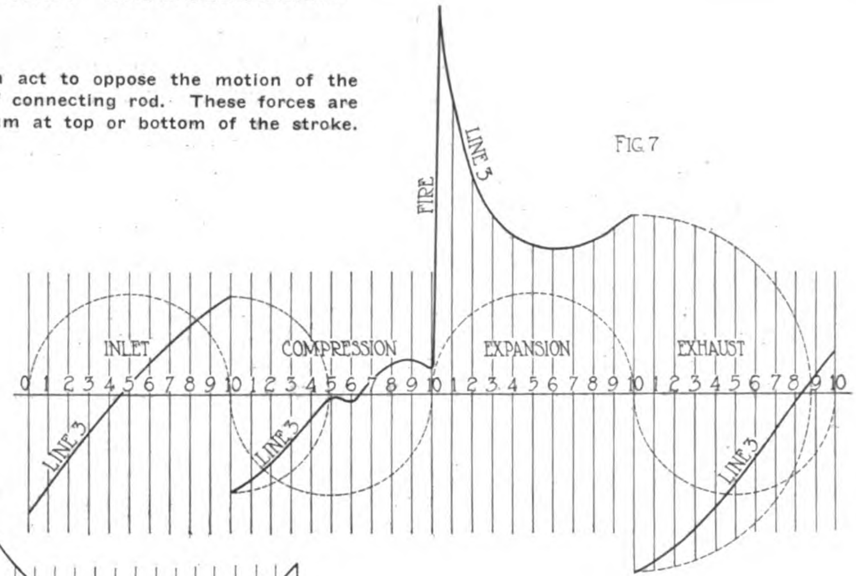

Fig. 7—Right—The algebraic sum of the ordinates of curves 1 and 2 shown in Fig. 6 combined at each vertical line and curve drawn through the resulting points. This curve is line 3 and shows actual pressure on piston, taking into account inertia forces as well as working forces. Positive pressure above and negative below zero line

angular velocity, and while in a multiple-cylinder motor it is impossible to detect with the eye any variation in the angular velocity, this nevertheless exists.

As an illustration of this variation, let us consider the example of a large single-cylinder stationary gas engine, the speed of which is regulated by a hit-and-miss governor. The explosions being considerable distance apart, it is possible from the general sound to detect that the motor speeds up just after an ignition and slows down before the next.

The purpose of the flywheel then is to distribute over the rest of a cycle the energy imparted to it at the time of the explosion stroke and inasmuch as the diameter and weight of any flywheel are necessarily constant, the only possible way in which it can accumulate energy is by increasing its speed. Conversely then any substraction of energy from the flywheel can only be accomplished at the expense of a decrease in speed.

CONSEQUENTLY, WHILE THERE IS NO READY MEANS OF DETECTING IT, A VARIATION IN ANGULAR VELOCITY OF THE FLYWHEEL EXISTS AND THIS IRREGULARITY OF MOTION IS TRANSMITTED TO THE RECIPROCATING PARTS AND CYLINDERS WHOSE REACTIONS TO THESE INTERMITTENT MOTIONS IS ONE CAUSE OF VIBRATION.

Use of Tangential Diagram

A tangential torque diagram, therefore, affords a very logical and clear means of comparing power overlap, and frequency and amplitude of torque changes. It has been used as a means of determining torque variations and for thereby computing flywheel weight to overcome as far as possible these variations. It may be used equally as well to compare torque variations of six and eight-cylinder motors.

Determination of tangential pressures, Fig. 1. The angle which the crankpin makes with the centerline of cylinder when at a given point on its path.

Line 1-3 is the magnitude of tangent force.

This magnitude is, therefore, on the same scale as that chosen to represent the pressure along the connecting-rod.

The working diagram of one cylinder could be represented in a continuous diagram such as Fig. 2.

The magnitude of pressure in the cylinder can be taken from an indicator diagram. Before this diagram can be made to correctly represent all the features we desire we must divide the work represented upon it into two classes, positive and negative.

The positive work is that produced by explosion pressure on the piston.

The negative work is that consumed in the motor itself. The only positive work is the expansion work.

To take account of these two quantities we proceed as follows:

First—Divide the indicator diagram by ten or more equally spaced vertical lines representing crank angles, Fig. 3.

Second—Plot the continuous diagram from an indicator diagram, Fig. 2.

Inertia Forces

Third—Draw a continuous diagram representing the pressure on crankshaft caused by the moving masses such as piston, piston pin and upper end of connecting rod, Fig. 5.

Fourth—Superimpose the continuous indicator diagram, Fig. 2, and the diagram, Fig. 5, representing pressures caused by moving masses, lines 1 and 2, Fig. 6.

Fifth—Take the algebraic sum of the ordinates of these two curves at each vertical line and a curve drawn through these points will give a combined continuous diagram representing actual pressures on piston, positive pressures being plotted above the zero line and negative below, line 3, Fig. 7.

If we now take the pressures represented by the above ordinates at each interval throughout the entire cycle we may, by the method shown in Fig. 1, determine the magnitude of their components acting tangent to the crankpin circle. The magnitude of these tangential increments, represented by t, may be plotted on our previous system of ordinates and the curve drawn through will then give a graphical representation of the tangential forces acting on one crankthrow for the complete cycle, Fig. 8.

For a multiple-cylinder motor the individual curves of tangential forces may be plotted one upon another in the sequence in which the cylinders fire, and arranged their proper angular distance apart on the developed crank circle. The resultant curve for the given number of cylinders may be plotted by taking the algebraic sum of the ordinates at each interval and passing a curve through them. Fig. 10 is the resultant curve of a four, Fig. 11 of a six and Fig. 13 of an eight so obtained.

This line will correctly represent the fluctuations of power in the given system of cylinders and by correctly interpreting it we shall be able to understand the functional ability of that system.

In order to compare the negative work of the different cylinder systems, Fig. 4 represents a theoretical diagram for a single cycle, the curves being constructed on the theory that they are adiabatic in character. Imagine the ignition pressure to be 25 atmospheres and the compression 5 atmospheres. The only abnormal feature of the diagram is the exhaust line which is straight and at the height of 5 atmospheres. In other words, it is assumed that the piston pushes the gases out against this back pressure. This is, of course, not actually the case, but the artifice was adopted solely for the purpose of exaggerating the negative work. This negative work is a large factor in determining the minimum tangent pressure, and as this minimum point is the one which is essential in comparing four, six or eight, it is desirable to accentuate that point as strongly as possible.

In parallel with this exaggerated diagram a correct diagram has been shown in which it will be seen that the minimum tangential pressure point is somewhat obscured, Fig. 9.

Figure 16 is a chart representing the conditions under which the six-cylinder diagram was constructed, and shows what is taking place in each cylinder at any time.

When the four versus six-cylinder controversy was at its height, illustrations similar to those shown in Figs. 16 and 17 were frequently employed to show the value of overlapping power strokes and we shall in the near future probably see similar pictures representing overlap of eight cylinder power strokes. While in the case of the six-cylinder motor these charts were approximately correct they would, in the case of the eight-cylinder V or all-in-line type motor, have a somewhat fictitious appearance. Such a chart for the latter motor would certainly show a beautiful overlap of power, but the fallacy of this is that in such a chart the negative work has been entirely neglected.

Interpretation of Diagrams

Returning to Figs. 11 and 12, both diagrams show equally enlarged negative

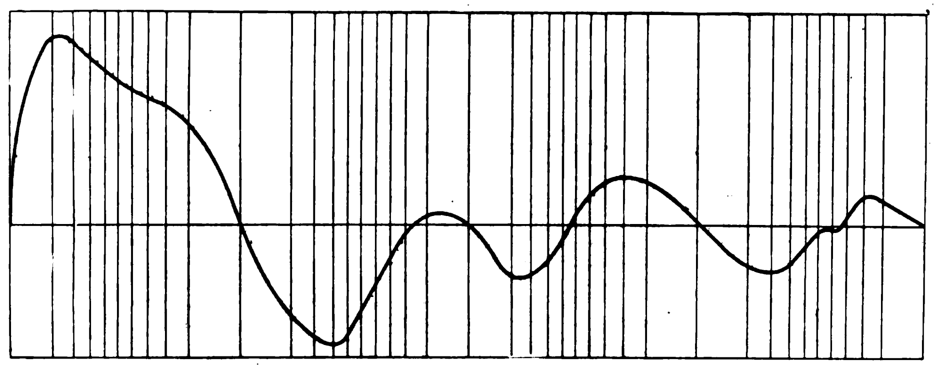

Fig. 8—Taking pressures at each of the ordinates in Fig. 7, at each interval of the cycle and determining the tangential components as in Fig. 1, the magnitude of these is here plotted on the same scale of ordinates to give the curve shown. It is a graphic representation of the tangential forces acting on one crank for a complete cycle. Those above base are positive forces, and below, negative.

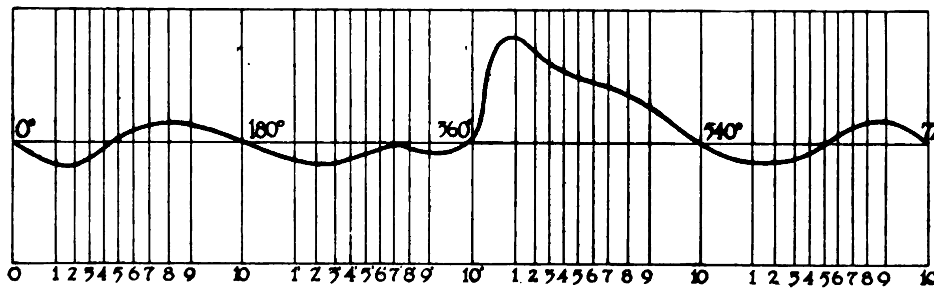

Fig. 9—This diagram has been secured in exactly the same way as Fig. 8, only the negative pressures are correctly drawn. This diagram is shown in order to make clear why the negative pressures are exaggerated. Since the negative work is a larger factor in determining the minimum tangential pressure and as this is essential to a compression of fours, sixes or eights, it must be better accentuated than a normal diagram will do it.

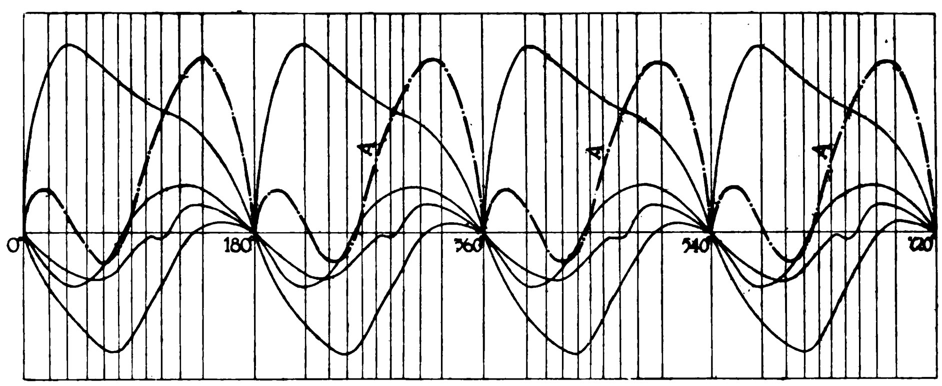

Fig. 10—This curve is the curve resulting from superimposing the tangential diagrams of four cylinders on the one cycle base line. That is, four curves similar to Fig 8, exaggerated negative pressures, are placed on the 720 degrees in order as they act in the cylinders, and then the ordinates added algebraically to get the resultant curve A, broken line, which is the combined tangential diagram for four cylinders

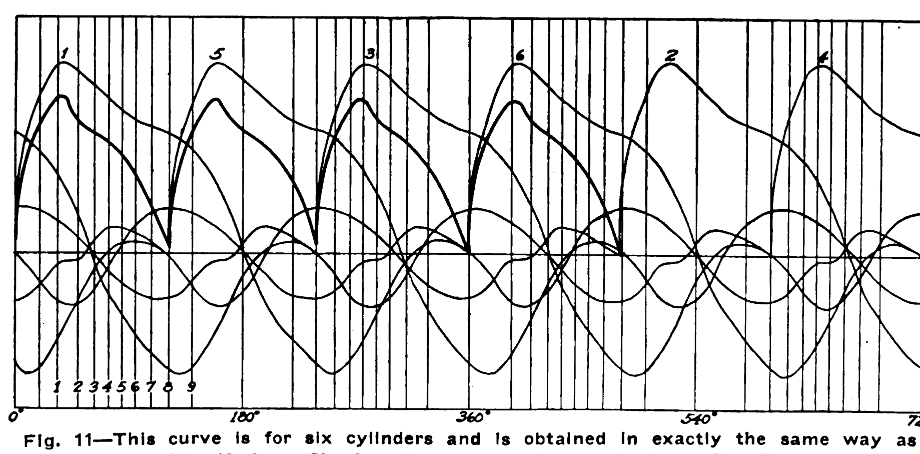

Fig. 11—This curve is for six cylinders and is obtained in exactly the same way as Fig. 10, from Fig. 8. The resultant line is the heavy line B

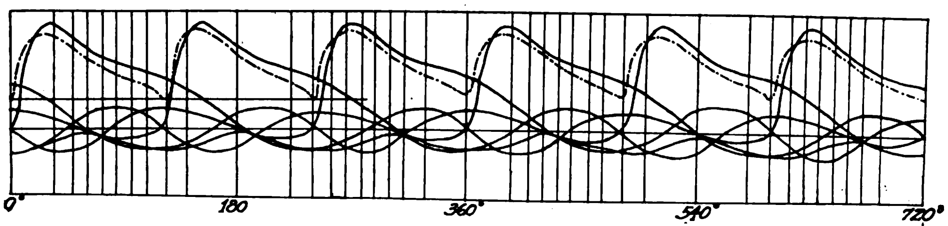

Fig. 12—The resultant of negative forces is shown in its relation to the resultant impulse curve of power forces (dotted). Although the six does not get its second cylinder into action until later than the eight, the second impulse begins when most needed, i.e., when negative forces are maximum. That is at point A, the second cylinder gets into action when the greatest negative force is acting at point B. The resultant of negative forces is obtained by adding algebraically all the negative ordinates of Fig. 12

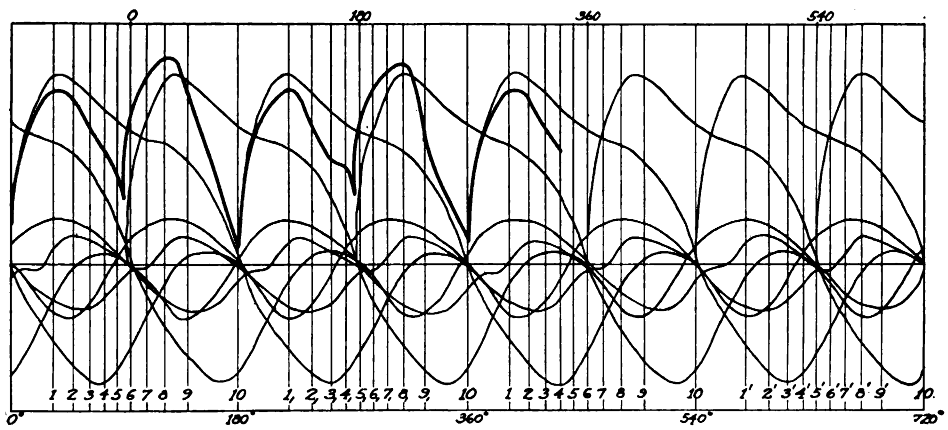

Fig. 13—This figure shows the resultant tangential diagram for eight cylinders combined in the same way as Figs. 10 and 12 from Fig. 8. The resultant line C, only a part of which is completed, shows the pressures acting at any part of the cycle as a result of the influence of 8 cylinders, considering inertia forces and working as well. We have already seen how this is done. The negative pressures are exaggerated as already explained

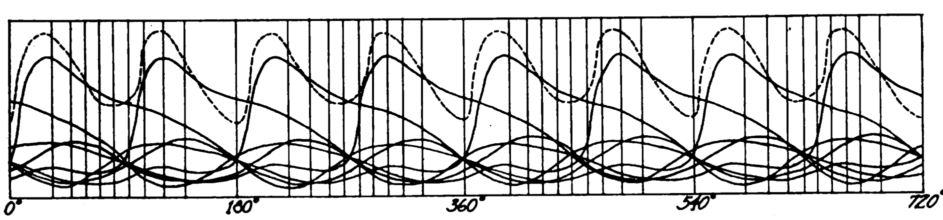

Fig. 14—A similar comparison as Fig. 13, only with an eight-cylinder motor. The overlap A comes where the negative forces are at a minimum B, or when least advantageous. The resultant of negative forces is obtained by adding all the negative ordinates of Fig. 14

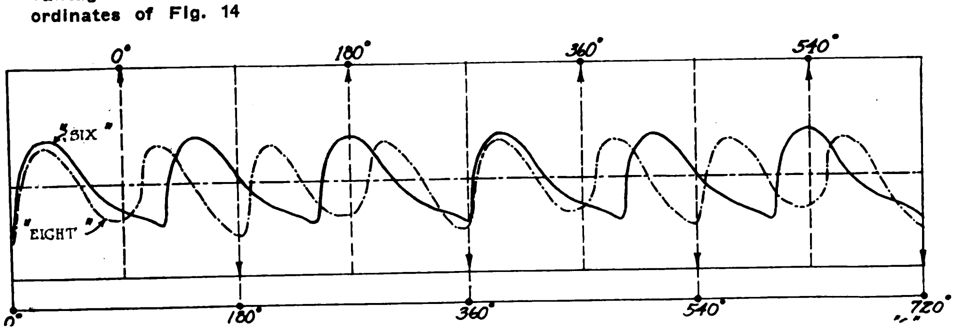

Fig. 15—A chart of superimposed power output curves of six and eight obtained as Figs. 10, 12 and 14 were obtained. Curve M is an eight, while curve N is for a six of equal displacement, power and stroke. It therefore has a larger base. The periodicity of the eight is shorter, but the amplitude is about the same. In one revolution the six has three waves and the eight four. This gives 1-3 more impulse, but not a third more torque. That is, the total of positive work of the two is the same. It is often claimed that the torque of an eight of the same power is 1-3 greater than of a six. This may be best seen by integrating and comparing the useful work inside both curves

forces, both motors have same bore and stroke; the eight has two more cylinders and consequently gives a proportionate increase in power. Upon examination we find the points of minimum torque to be approximately the same with both six and eight, which fact is due to the action of the negative forces. That is, the minimum torque ordinates of both curves are about the same.

As regards overlap of power strokes, the six does not get its second cylinder into action until later than the eight, but this actually proves to be fortunate because it comes into action at a point where the negative forces are at a maximum. This will be seen in Fig. 13 where the resultant negative force is shown below the zero line.

In the eight the *overlap comes in a place where the negative forces are at a minimum.* Fig. 14 shows this in a similar way to Fig. 12.

As was previously mentioned, exaggerated diagrams were made for the purpose of showing that the minimum torque of an eight-cylinder motor having same bore and stroke as a six with two extra cylinders acting is no higher than the minimum torque of the six with two less cylinders.

On an Equal Power Basis

The highest peak of the eight-cylinder tangent curve is higher than that of the six because of the two additional cylinders. Although, Figs. 11 and 13 represent motors of same bore and stroke, to be absolutely fair let us in Fig. 15 represent a six and an eight V or all-in-line type of the same stroke and piston displacement, the six consequently having a larger bore.

In Fig. 15, which is a summary of previous curves, we find that the power output of both six and eight-cylinder (either V or all-in-line) motors should be the same because if they are of same displacement the integral of both curves should be the same. The periodicity of the curve is shorter on the eight than on the six, but the amplitude is about the same. In one revolution the six has three waves, while the eight has four, which is one-third more impulse, but by no means a third more torque. That is, the sum total of positive work of the two motors in the same revolution is practically the same, instead of being the often-claimed 33 1-3 per cent. greater amount in the eight. This may be seen by integrating and comparing the useful work shown by both curves. Whether this could be considered an advantage or not is open to question. If there is any advantage, it is apparently small, and not near as much as the advantage gained by going from four to six, for the four has an absolutely dead period.

From what is revealed by the foregoing curves it is questionable if the advantage gained is sufficient to justify the eight-cylinder construction.

Various types of curves have been developed for eight-cylinder motors, some nearly straight lines, while at the same time similar curves for the six showed comparatively wavy lines.

It would appear that such curves have been slightly conventionalized or else the negative forces have been somewhat neglected. Had they been taken into con-

Yellow Rays Are Non-Glaring

Yellow Headlight Rays Do Not Affect Eye—Objects More Easily Seen In Colored Light

By J. W. Esterline

INDIANAPOLIS, IND., Editor THE AUTOMOBILE:—The danger of operating an automobile at night on city streets or country roads with brilliant, dazzling, blinding headlights is proven by the many accidents recorded monthly, caused by the driver running off the road while blinded with the headlights of an approaching car. Because of this situation the present controversy on non-dazzling headlights must be considered from the standpoint of the country as well as the city; and further, it must be considered from the standpoint of safety to the motoring public, as well as to other classes of traffic.

It is equally dangerous to motorists and the public to drive on city streets or country roads at night without headlights. The almost world-wide agitation against dazzling headlights is indicative of an interest in and the demand for a type of headlight which will meet the requirements of night driving on city streets or country roads.

The requirements of a headlight which will satisfactorily meet all these conditions are varied and difficult to embody in a single piece of simple apparatus. The manufacturer is called upon to produce a lamp which the driver riding behind can clearly see the street or road ahead and which persons approaching or crossing the path of the car can see at a good distance.

Some cities have passed ordinances prohibiting the use of headlights, and while this doubtless reduces the discomforting blinding, it seriously increases other dangers. There can be no objection to plenty of light if that light is not blinding, and it is positively safer to pedestrians and drivers to use the headlights, if the light they give is such as to cause no discomfort or danger.

Headlights a Necessity

The rays of a headlight are a silent warning to persons walking, and to drivers of horse-drawn or motor vehicles, of the approach of a car from behind. The light from a car approaching an intersection of streets obviates many collisions, and the sweeping of the rays of a car making a turn is a most effective signal of the driver's intentions. In the darker streets of cities, it is positively dangerous to require motor cars to operate without headlights.

A brilliant headlight sufficiently dimmed to be non-blinding, gives no driving light. Since it can be instantly controlled by the driver, the presence of a police officer is almost necessary to insure its use. Because it does not give a good light to drive by, the driver does not dim his lights except when compelled to. When they are dimmed to the point where they are not blinding, the light is so faint that it is useless as a warning signal.

While it is possible for the authorities to control the situation somewhat in the larger cities, the only satisfactory solution which will give adequate protection in the country, is the use of a headlight which will give a sufficient driving light and at the same time be non-blinding.

It will be interesting to note the reasons why we can see better in a yellow light, and why the blue and violet rays set up an almost immediate irritation.

When we look at the human eye, Fig. 1, we see through

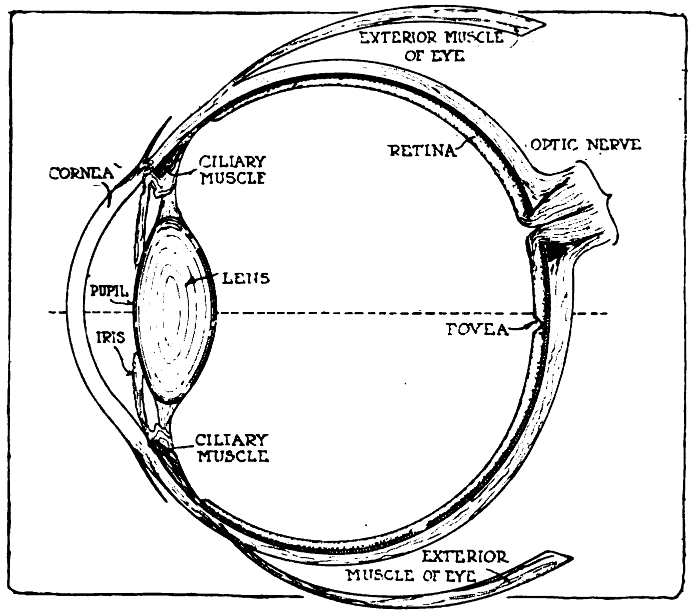

Fig. 1—Construction of the human eye. The pupil is shown at the left and the retina at the right

the clear, transparent cornea a circular colored portion, the iris. In the center of the iris is an opening, the pupil. This opening has the property of enlarging itself or contracting, according to the amount of light striking the eye. Thus, when we pass from a dark room into a brilliantly lighted room, the pupil almost instantly contracts.

It is significant that the contraction in passing from darkness into bright light is accomplished almost instantly, whereas the enlargement in passing from bright light into darkness is accomplished comparatively slowly. This strongly indicates that the function of the pupil is protective rather than regulative, which accounts for the fact that when we look into the front of a brilliant headlight for an instant we are unable to see anything else in our path.

It should be noted, also, that the range within which the pupil can enlarge itself or contract, is much narrower than the range of light intensities to which the eye is normally exposed. In other words, the protection offered by the pupil is only partial, and is not sufficient to entirely protect the eye from the bright conditions of illumination to which it is often exposed.

The Eye Construction

Close behind the pupil in the human eye, Fig. 1, lies the crystalline lens, whose function is of course similar to that of a lens in a camera. There is, however, this important difference in operation. The clearness of the image formed by the lens of a camera is maintained, whether the object is far or near, by changing the distance between the lens and the ground glass, or sensitized plate. Obviously in the human eye such changes cannot be made. The clear focus of near or distant objects is therefore accomplished by changes in the curvature of the crystalline lens. Around the outside of the lens runs a ligament, and this ligament is attached to the ciliary muscle. By contraction or relaxation of the ciliary muscle a greater or lesser curvature of the lens is accomplished.

The crystalline lens is non-achromatic. In other words, it does not bring the red rays, the yellow rays and the blue and violet rays simultaneously to a focus at the same point. Light not brought to a focus at the right point produces a blurred image, as we know from the observation of the ground glass plate of a camera when the lens is moved out of adjustment.

Yellow Ray Gives Vision

In ordinary white light, the yellow rays are brought to a focus on the retina; the blue and violet rays, in front of the retina, and the red rays, just behind it. The distinct element of ordinary vision is, therefore, given by the yellow rays, the blue and violet rays serving only to blur the sharp outlines of the visualized object. This blurring is not always detected by close observation, but it is sufficient to require a sufficiently increased intensity of illumination on the visualized object in order that the exact outline and finer details of the object may be seen distinctly. It is clear, therefore, that the yellow is the useful part of white light and that the violet and blue can be dispensed with without altering our ability to see distinctly and with an attending degree of comfort to the eyes.

Let us suppose that we are viewing an object which is illuminated entirely by a greenish-yellow light. Let us further suppose that the intensity of illumination is just sufficient to disclose some certain detail of the object. If, now, the object be illuminated by the same intensity of white light, instead of the greenish yellow light, the fine detail previously observed can no longer be seen. A higher intensity is required to disclose this detail.

Detail in Vision and Color

Expressed in scientific terms, we can say that visual acuity, or the ability to distinguish fine detail, is in a considerable degree dependent upon the color value of the light by which the object is illuminated.

It has already been pointed out that the crystalline lens is non-achromatic. When, therefore, light having rays of all colors, as in the case of white light, is reflected from the object to the eye, the blue and violet rays are brought to a focus in front of the retina, and the red rays directed toward an imaginary focus behind the retina. The red, blue and violet rays serve, therefore, to blur the otherwise sharp image formed by the yellow rays on the retina.

Now, when the object is illuminated by monochromatic light, that is, by a light of a single color, the rays are brought to a sharp focus on the retina, and there is no blurring effect. In other words, the non-achromatic lens can adapt itself to any color of light, but in the presence of light of all colors, combined in approximately the proportion of white light, it adapts itself to the yellow rays.

Research has conclusively established that monochromatic light enables detail to be distinctly seen at a lower intensity of illumination than when the object is viewed by white light.

It has also been established that different colors of monochromatic light vary in their power to disclose detail.

Yellowish-Green Light for Detail

The power of disclosing maximum detail with minimum illumination seems to be possessed by a yellowish-green color.

From the above it will be clear that we can see more distinctly with the same light, or equally distinctly with less

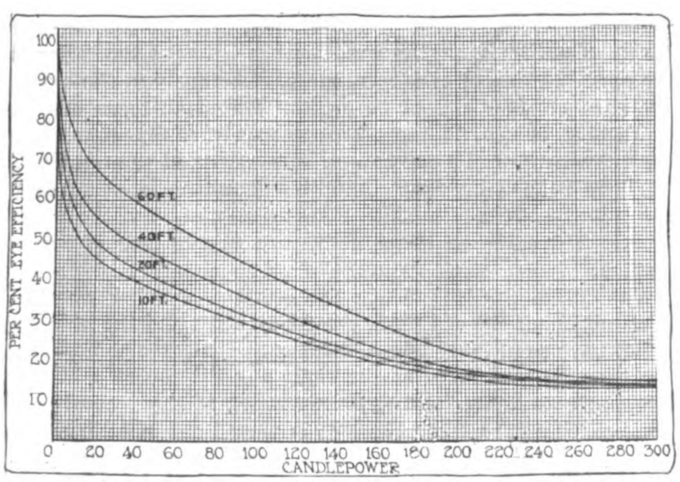

Fig. 2—Curves showing the relation between the efficiency of the eye and the candle power of the light at various distances from 10 to 60 feet

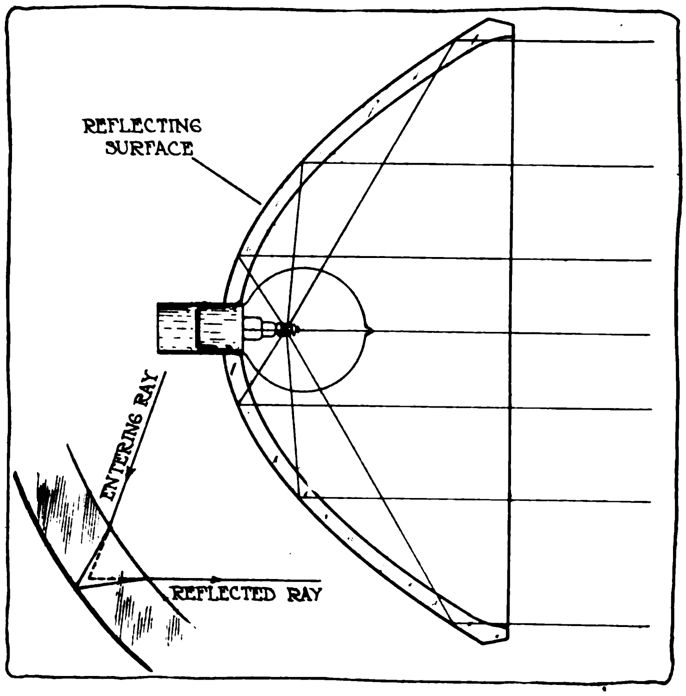

Fig. 3—Diagram showing the rays of light reflected from an ordinary headlight. In the left corner is shown the path of the ray through the glass. The dotted lines show the apparent path of the ray due to the difference in index of refraction between the air and the glass

illumination, if that light be of a greenish-yellow color.

The influence of colors of light has been studied by a number of able investigators, among whom Laporte, Broca, Dow, Bell, Ashe and Luckiesh have done especially notable work.

Cuts Eye Efficiency

In considering the question of headlights for night driving, it must be borne in mind that the human eye when constantly subjected to an intense white light reflected from the road quickly loses its efficiency. In other words, the brilliancy of the light itself reflected back into the eye of the driver, soon lowers the efficiency of the eye to a point where the ability to see is less than it would be if the light were less brilliant.

The lowering of the eye efficiency depends upon the total amount of light which enters the eye, and upon the angle with the line of vision at which each integral portion of light enters the eye.

Eye Efficiency and Brilliancy

The curves in Figure 2 show the relation between the efficiency of the human eye and the intensity of light entering the eye at 0 degree angle with the line of vision. Curves are given for the source of light at different distances from the eye. It will be observed that a very small intensity of light entering the eye along the line of vision materially cuts down the efficiency of the eye. When the intensity of the beam reaches 300 candlepower the efficiency has been tremendously reduced. These curves show clearly why when a beam of several thousand candlepower shines directly into the eye, it is impossible for the driver of a motor car to see anything in his path, since an increase of from 20 to 300 candlepower in the beam of light entering the eye lowers the efficiency from 70 to 12 per cent.

The curves also show that the efficiency of the eye is very little affected by the distance of the light source or light reflecting object from the eye.

Steinmetz on Optics

Dr. C. B. Steinmetz, eminent engineer and physicist, in "Radiation, Light and Illumination," has the following to say concerning blinding, irritating light:

"The light which enters the eye is converted into heat, and

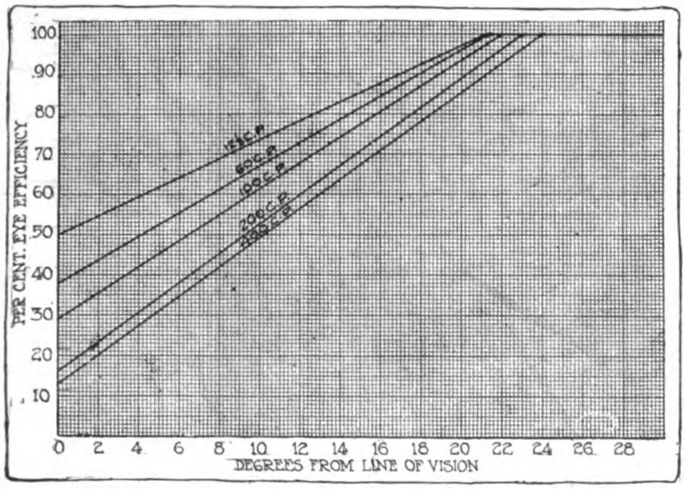

Fig. 4—Curve showing the relation between the efficiency of the eye and the angle at which the light strikes it

if its power is considerable, it may be harmful or even destructive, causing inflammation or burns. This harmful effect of excessive radiation is not incident to any particular frequency, but inherent in radiation as a form of energy. It is, therefore, greatest for the same physiological effect, that is, the same amount of visibility, for those frequencies of light which have the lowest visibility or highest power equivalent, that is, for the red and the violet, and least for the green and yellow, which for the same amount of visibility represent least power. Hence, green and yellowish-green lights are the most harmless, the least irritating to the eye, as they represent the least power.

"The human organism has by evolution, by natural selection, developed a protective mechanism against the entrance of radiation of excessive power into the eye; at high intensity of illumination the pupil of the eye contracts and thus reduces the amount of light admitted, and a sudden exposure to excessive radiation causes the eyelids to close. This protective mechanism is automatic; it is, however, responsive to long waves of radiation, to the red and yellow light, but not to the short waves of green, blue and violet light. The reason for this is apparently that all sources of excessive radiation which are found in nature, the sun and the fire, are rich in red and yellow rays, but frequently poor in rays of short wave length."

Government for Yellow Light

The United States Bureau of Standards in Bulletin No. 28 recommends a yellow light as causing the least fatigue, as follows:

"A light yellow screen is very effective in eliminating a purple haze in viewing distant objects and thus heightening contrast in an otherwise 'flat' field. The extreme contrast produced by the direct reflection of sunlight on water cannot be avoided (being nearly non-selective), but the maximum intensity may be reduced at the sacrifice of the low lights, or the glare may be 'softened' with a yellow or orange screen which eliminates the more fatiguing blue and violet."

The Master Mechanics Association of the steam railroads of the United States, conducted a series of tests for 9 months on different types of lamps for railway use. From the report of this committee, we quote one paragraph which is of particular interest, coming as it does from the committee appointed to report on this subject, as it bears out what has already been said about the ability to see in different kinds of light:

"The headlights listed above were first tested to ascertain the distance at which dummies could be seen with the dummies standing abreast between rails. Three dummies were used—one dressed in dark blue overalls and jumper, known as the 'dark dummy'; one dressed in blue and white striped overalls and jumper, known as the 'medium dummy,' and one dressed in white overalls and jumper, known as the 'light dummy.'

"The ability to see dummies with lamps of moderate intensities is fairly well established by the visibility curves, and that there is no apparent difference in the ability to see the dummies with a given intensity of light, whether the source is oil, acetylene or incandescent lamps.

"It will be noted, however, that with arc lamp No. 19, with 60,000 apparent beam candle power, the dark object could be seen only 557 feet. Calculating from the visibility curve of the dark dummy for oil, acetylene and incandescent lamps, the dark dummy would be seen at the same distance with an apparent beam candle power of only about 14,000. This effect can be attributed only to the predominance of short violet waves in the arc rays to which the eye does not readily respond."

Cutting Out the Glare

In the "Golden Glow" headlights, non-blinding is secured by altering the *quality* of the light given by the incandescent lamp, and by this means the glaring effects are greatly reduced without appreciably altering the illuminating qualities.

In this type of lamp, a golden green parabolic glass reflector is used, the color being obtained by a special mixture in the manufacture of the glass.

Green, Orange and Yellow Needed

It is also equally well established that the colors of light of ordinary vision are the green, orange and yellow. For these reasons it is possible to remove the violet and blue rays from a beam of light, rendering it much softer and less irritating, without seriously affecting its illuminating qualities.

In the manufacture of the Golden Glow reflector, the ingredients used in making the glass are such as to give it a golden green color. The lamp bulb being in front of the reflector, and the silver reflecting surface on the back of it, it is necessary for the light in passing from the bulb to the reflecting surface to go through the glass, and on leaving the reflecting surface, it passes through the glass a second time. Fig. 3.

The colored glass subtracts from the beam of light given by the bulb all of the rays above the green, *i. e.*, the violet and the blue, and passes those of all colors below it, so that while the light given by the filament of the lamp itself is a brilliant white, the beam of light from the headlight is a golden yellow with a slight tinge of green.

We have already stated that the lowering of eye efficiency depends upon the angle at which the light enters the eye. Figure 4 shows the relation between the efficiency of the eye and the angle with the line of vision of the beam of light causing the depression. These data are of the highest value since they show that the lowering of the efficiency of the eye ceases when the angle between the beam entering the eye and the line of vision is 24 degrees or more.

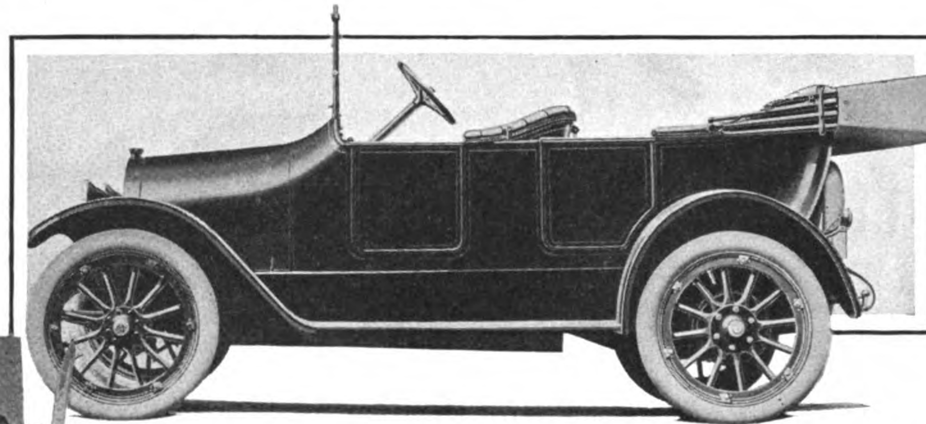
This means that on the assumption that the lamps on a motor car are on a level with the eye and that the rays leaving the lamp are parallel, all objectionable blinding would be overcome by tilting the lamps so that the beam leaves the lamp at an angle of 24 degrees below the horizontal.

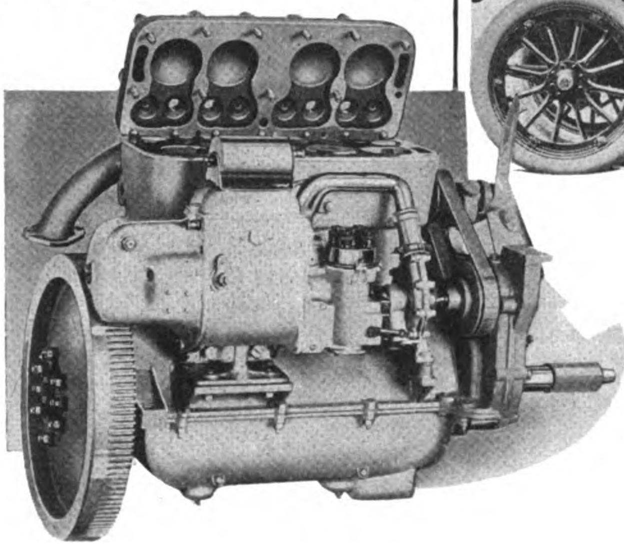
It is a fact that the eyes of persons approaching are usually somewhat above the plane of the lamps so that in most cases a tilting of the lamps by an amount equalling 15 degrees is sufficient.

Numerous tests made by this company indicate that by using a greenish yellow light, which is the light in which the eye works most efficiently, and by slightly tilting the lamps, a satisfactory roadway illumination is obtained which is not objectionable to other kinds of traffic, and which adds materially to the safety of all forms of traffic.—J. W. ESTERLINE, President the Esterline Co.

One Cartercar Model for 1915

Friction Drive Continued —Price Unchanged— New Chassis Continuation of This Year's Smaller Model—





Above—Cartercar five-passenger touring car selling for $1,250. Left—Motor with detachable cylinder head and combined starting and lighting system mounted on the right side and at the rear of the pump

A POLICY of concentration has been adopted by the Cartercar Co., Pontiac, Mich., for the coming season which has resulted in the decision to market but one model of chassis to be known as model 9. This year was given over to the manufacture of two chassis, models 5 and 7, the former higher in price and larger than the latter.

The new model 9 is practically a continuation of this lighter model 7, though it has undergone some refinement both mechanically as well as in outward appearance.

Friction drive remains practically unchanged, it having proven satisfactory in the hands of Cartercar users in practically its present form for many years.

Price Not Changed

There has been no change in price, the new model 9 selling for $1,250 with full equipment just as did its predecessor, model 7. Only two bodies are supplied, a roadster and a touring type. These are up to date, and in changing to the streamline form the Cartercar Co gets into line with present-day demands of the buying public. Body fashion dictates a sloping hood, cowl rounding gracefully to it, round-top radiator, smooth-sided body, domed fenders with protecting edges fastened with concealed rivets, the elimination of side lights, etc. And in every one of these respects, the Pontiac concern has met these dmands in thoroughly commendable manner.

One change in the general body construction is the addition of a door to the right or drive side. This year there is no entrance here, and in order to accommodate this, the throw of the speed lever and emergency brake lever has been brought a little forward.

Lower Gear Ratio

The gear ratio in the rear axle has been lowered from 3.45 to 1 to 4 to 1. This makes the work of the motor somewhat easier and really gives the car more pulling power.

Tires have been increased from 32 by 3 1-2 to 33 by 4 inches. In addition, the rears are now non-skid, as against plain treads heretofore.

So as not to make any difference in the reduction ratio between motor and wheels, the copper tranmission disk has been decreased in diameter 1 inch which makes up for the increasing of the tire diameter by 1 inch.

Although the motor is practically the same in design as in 1914, being 3 1-2 by 5 inches, and having its cylinders cast in a block of L-head form with detachable head, it is really more powerful due to a slight increase of valve size and other slight changes. The valves now are 1 13-16 inches in diameter in the clear as compared with 1 11-16 inches formerly.

Wires in Flexible Conduits

Another noteworthy refinement is the placing of all wires within flexible conduits to protect them against any of the hundred and one conditions which would result in short circuits, broken circuits and the like. Aside from the efficiency of this type of wiring it makes a much cleaner and neater job.

The Cartercar motor is of conventional form with valves all on the left along with the intake and exhaust manifolds, the latter running back to the exhaust pipe above the intake which is of the two-branched type. The power plant rests upon two frame cross members which are arched downward. It is really three-point suspended from these cross pieces, there being two points of attachment to the rear member by means of integral projections from the upper half of the horizontally split crankcase, while the front of the engine rests upon the forward member at one point only.

The motor develops about 30 horsepower at 1,700 revolutions per minute and its cylinder dimensions give it a piston displacement of 192.5 cubic inches.

Detachable Cylinder Heads Used

The detachable head construction is noteworthy in that it allows for the complete exposure of all of the pistons and cylinders together with valve pockets and valves by the removal of the steel holding bolts. Between cylinder block and head there is interposed a copper gasket.

The working parts are standard in every respect, and are machined to close limits as well as being accurately balanced against vibration which is the enemy of quietness and smooth running. There are three main bearings for the crankshaft and three for the camshaft, both of which are drop forgings of high-carbon steel. The cast iron pistons carry three rings each. Valves are of the standard form seating at 45 degrees, and operating through the intermediary of adjustable tappets working against the cams. The camshaft and generator and pump shaft are operated by helical timing gears completely housed at the front. There are two valve covers inclosing the valve mechanisms, and in these covers there are vents which communicate through the tappets with the crankcase and thus serve as breathers.

The motor dimensions are:

Pistons, length, 4½ inches.
Connecting-rod length, 10⅝ inches.
Piston pin bearing, ⅞ by 1⅞ inch.
Connecting-rod lower bearing, 1⅝ by 2¼ inches.
Front crankshaft bearing, 1⅝ by 3 7/32 inches.
Center crankshaft bearing, 1⅞ by 2⅜ inches.
Rear crankshaft bearing, 1 15/16 by 3 7/16 inches.
Front camshaft bearing, 1⅛ by 2 inches.
Center camshaft bearing, 2⅛ by 1 inch.
Rear camshaft bearing, 1 by 1¾ inches.
Flywheel diameter, 14 inches.

The cooling system is of the positive circulation type in which a centrifugal pump driven by the same shaft as the generator and on the right side of the engine, is employed. A large tubular radiator and three-blade, belt-driven fan do their part in the cooling.

The splash system of lubrication finds efficient application and uses individual troughs under each cylinder into which the rod ends dip. A plunger pump, operated from the camshaft, supplies these troughs from the oil base and keeps them at a constant level.

Three-Function Delco Used

The electrical part of the Cartercar is cared for by the standard form of combination Delco unit which incorporates the three functions of cranking, lighting and ignition. The ignition distributer is an integral part of the unit and the ignition current is supplied by the generator in conjunction with the storage battery. The cranking is done by the meshing of the gears with teeth in the rim of the flywheel when the pedal is pressed. This operation also transforms the unit into a motor, sends current from the storage battery and as soon as the pedal is released, the motor-generator returns to its normal condition as a generator.

Friction System Unchanged

The Cartercar drive system is of very simple form as shown in the chassis illustrations. Due to the fact that it is of friction type, a clutch, which is essential to every ordinary type of car, is dispensed with as is also the gearset with its usual three speeds forward and reverse.

From the flywheel, which is not inclosed, there is a short shaft extending back to the copper-alloy transmission disk which has a diameter of 19 1-4 inches in the new car. Due to the positive connection between this disk and the flywheel, the disk rotates at the same speed as the crankshaft and is in the same plane as the flywheel.

Back of this disk and mounted at right angles to it is the fiber-faced friction wheel, 21 1-4 inches in diameter. This wheel is mounted on a cross shaft on which it slides, the shaft having a bearing on either frame side member. At the right side the shaft carries a sprocket over which a silent chain runs and conveys the power back to the rear axle.

Thus when friction disk and wheel are in contact, friction causes them to roll together and connection is then made between motor and rear wheels through the intermediary of the differential gears in the rear axle.

The construction of the drive mechanism is very substantial and efficient from a power transmission point of view. The disk shaft and housing for the driving release spring are carried on a couple of frame cross pieces, and the shaft ahead of them is provided with two universal joints. The driving chain running from wheel shaft to axle is fully inclosed by a housing which is horizontally split into two halves and which bolt to the differential housing through flanges.

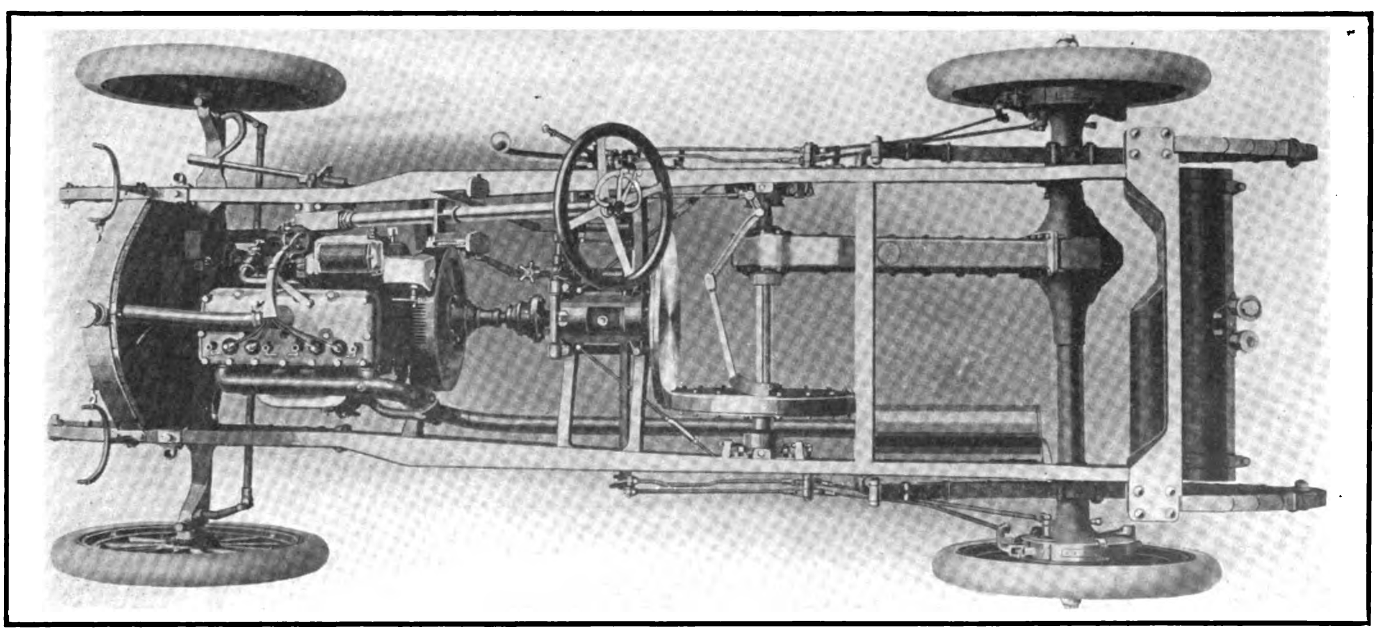
The rear axle is of the three-quarter floating type with bevel gear differential within the ring sprocket over which the chain runs. Single bearings are placed under the rear hubs, and Hyatt bearings are used for the differential.

The wheelbase of the model 9 Cartercar is the same as model 7, measuring 106 inches. The tread is 56 inches with an option of 60 inches for Southern roads.

Steering and control are on the right as heretofore, the gear being of the worm-and-nut type, operating from a 17-inch wheel carrying spark and throttle levers and horn button.

In connection with the new bodies, a convenient arrangement of the various instruments on the instrument board is made. These are all grouped within easy reach of the driver, and night driving is made convenient by the dash lamp which illuminates them.

The equipment includes a rain vision ventilating windshield, top with quick-acting curtains, demountable rims with one extra, electric horn, speedometer, gasoline air gauge, license tag holders, full set of tools and jack.



Plan view of chassis showing the location of the motor, and the details of the friction transmission and enclosed silent chain drive

Many Car Makers Strain Tires By Overloading Them

The Automobile Engineers' Forum

Car Maker Dictates Sizes—Oversize Popular Equipment—Absorb Shocks Better

BATAVIA, N. Y.—Editor THE AUTOMOBILE—We do not feel that the criticism that tires perish through cutting and not through wearing away of the tread is well founded as an argument in favor of not using oversized tires, for the reason that in the first place an oversized tire is less liable to suffer from injury by cuts or stone bruises which fracture the fabric, than the tire equipment which at the present time most car manufacturers elect arbitrarily to use on their product.

Car Maker Dictates Sizes

This latter point is the main reason why oversized tires are needed at all. The manufacturer of cars seems to occupy the enviable position of being able to dictate to most tire manufacturers what sized tire equipment they are to figure on, if they want his business, and the tire manufacturer for one reason or another generally figures the way the car manufacturer insists he shall, and this in spite of the fact that the tire manufacturer publishes a schedule showing the load capacities of these tire sizes.

Oversized tires would not be necessary at all if, in the first place, car manufacturers used sizes on their original production which carried this production, and if tire manufacturers either did, or were in the position to, compel the car manufacturer to equip with tires adequate to the weight strains.

It is just as logical for a car manufacturer or a consumer to say that there is no economy in an oversized tire as to claim that a 20-horsepower engine in a car weighing 4,500 pounds is adequate by comparison with a 40 or 50-horsepower motor for the same car. The 20-horsepower motor would probably move the car, but it would be seriously strained in doing it, just as an undersized tire is strained in carrying the same car.

The car manufacturer for the past year or two has shown an inclination to recognize the need of oversized tire equipment, and has bettered the condition which led some years ago to the production of oversized tires.

Oversize Soon to Be Regular Equipment

The car buyer is pretty well educated these days when it comes to knowing what size tires a car of given weights should be equipped with. The car buyer generally gets what he insists upon getting, even if he has to pay extra for it. What he pays extra for this year is generally next year's regular equipment, and the time is not far distant, apparently, when all manufacturers by reason of greater knowledge of the needs of the case, coupled with the element of competition, will practically eliminate the need of a tire which today is called an oversized tire, and what now is known as "oversize" will in all probability be regular.—W. P. BERRIEN, sales manager, Batavia Rubber Co.

Recent Racing Experience Favors Use of Oversize Tires

RUTHERFORD, N. J.—Editor THE AUTOMOBILE—We have found the oversize tires to give better service and considerable more mileage, easier riding than the smaller tires. Our tests have been made on various cars, and we can refer you to one case on a Chalmers coupé on which the double oversize was used with proper change of rims. Besides easier riding this set of tires stayed on the car over 15 months, giving something from 7,000 to 8,000 miles on the rear. We can also cite an instance where last year at Indianapolis the Mercedes driven by Ralph Mulford used oversize tires in the rear. The result is a published fact that the tires went through the 500 miles without any tires changed.

Previously the racing cars used about a 4-inch cross section and 4½-inch in the rear. The size tires used this year were anywhere from ½ to 1 inch larger in cross section. We cite a particular case with the foreign cars in which they used a 35 by 6-inch tire while last year they used 35 by 4½. Smaller tires make ruts in the road and are more liable to cuts than the larger casings. The larger cases have more tread than the smaller ones, and have greater carrying capacity and air space. More tires are damaged on the curves than on the straight away. The tires have a rolling effect on curves and if the cross sections are not large enough they will suffer severe cuts and blow out. The general public is beginning to realize that oversize tires are better and more economical.—BRAENDER RUBBER & TIRE CO.

Oversize Tires Have More Cushion and Absorb Shocks Easily

AKRON, O., Editor THE AUTOMOBILE:—We note that there has been some criticism on the oversize tire on the grounds that the average tire perishes from cutting and not from wearing away on the tread. This would seem to be an argument in favor of the oversize tire which has more cushion and naturally absorbs shocks and bruises to better advantage.

The manufacturers of a car necessarily adopt some standard equipment which their engineers and the tire people consider adequate to carry the weight and give satisfaction generally.

Conditions Determine Requirements

Take, for example, twenty cars that are shipped to many different sections of the country. Probably the tires on seventeen of these cars stand up and make a good showing, but the tires on three of the cars give trouble continually. It simply means that the different conditions under which these three cars are used make it necessary to use larger tires in order to secure the expected service.

The oversize tire was primarily designed and intended for these exceptions, but it is becoming a practice among experienced car owners to use the oversize tires generally and in many instances to specify them as original equipment for their new cars.

Firestone oversize tires have an extra thickness of fabric and rubber, consequently the added strength and larger air cushion of approximately 30 to 40 per cent. insure distinct advantages. The resiliency of the larger tire adds to comfort, reduces vibration to the mechanism of the car and the traction slippage on the rear wheels is less.

There is not enough difference in the extra weight of oversize tires to cause any difficulty with power, differential or rear axle. These are important things to consider, particularly with a small car.

Added strength, resiliency and mileage without expense or inconvenience of changing wheel equipment are features which mean more certainty and pleasure to motoring.—L. GREENWALD, Manager Service Department, Firestone Tire and Rubber Co.

Does Not Favor Oversize Tires—No Complaints

MILLTOWN, N. J.—Editor THE AUTOMOBILE:—In regard to oversize tires, we think it advisable to use tires made especially to fit the rims on which they are to be used.

While we are not in favor of oversize tires, we might add that we have heard no complaints from those who use them.—MICHELIN TIRE CO.

Compares 6 vs. 12-Volt Controversy to 110 vs. 220-Volt

CLEVELAND, O.—Editor THE AUTOMOBILE:—In regard to the respective merits of the six volts vs. 12 volts wire system, we are unable to express any opinion as to which is the better. From a battery maker's standpoint it makes no difference which system is used.

We think you can compare this to the illuminating system. We doubt if there is any advantage—of one over the other between the 110-volt and 220-volt. In illuminating systems there might be a slight advantage in favor of the 220-volt system due to the fact that the loss due to wiring would be less on account of the higher voltage. There is no doubt but what it would be a good thing if every one would adopt one standard, but, as outlined above, we can see no advantage of one system over the other, when everything is considered.—T. A. WILLARD, Willard Storage Battery Co.

Replies to Readers—Gives Formula for $250 Automobile

DETROIT, MICH.—Editor THE AUTOMOBILE:—I notice in your issue of September 10 an article asking for information on my Automo Pill. This request is misleading and very inconsistent. However, the articles have accomplished their purpose in one instance at least.

Reviewing the subject in every detail and refraining from sarcasm, which seems to be the basis of Mr. Britt's query, I will say I have never mentioned or prescribed the pill remedy, and were it not for the fact that Mr. Britt is all wrong, I would not be able to give any information, as he seems to answer every query he asked to suit himself.

Mr. Britt asks do I want everything standardized and continues by asking if I realize that it spells stagnation, but in another way. Why not tell us the other way. I do want everything standard that I can have standardized. To explain more fully and prove why, I will give an example of what standardization means. Supposing that all other concerns start making Ford cars identical with the present Ford in every respect. The first thing noticeable would be a reduction in price, next an increase in demand, due to reduced cost; next a refinement in detail; next better and more complete equipment and shortly we would have our ultimate two-hundred-and-fifty-dollar car fully equipped and instead of the present demand of 500,000 cars per year, we would be obliged to furnish 5,000,000. Does this look like stagnation? We will then be able to stop into any first class hardware store and buy a part just as easy as we now buy a bolt and nut for a carriage or wheelbarrow.

In query 2, Mr. Britt asks, "Is it fair to say that the U. S. Government is throwing away money when testing fuel," and answers his query by telling us that alcohol is too high in price for a long time to come. It is very evident that Mr. Britt is not aware that the Wood Waste Distillery Co. of Wheeling, W. Va., is today making a small machine that will produce 5 gallons of alcohol from one bushel of corn, which with corn at 60 cents per bushel, the average price, figures 12 cents per gallon. Does this not prove conclusively that alcohol is not too expensive; on the contrary, alcohol is cheaper and far superior to gasoline in every way, providing it is used in a properly designed engine.

Regarding the self-starting, the elimination of gears, clutches, etc. If Mr. Britt will look in the official gazette, Jan. 28, 1902, Patent No. 692,218, he will find a description of an engine that will fulfill all the above requirements, that weighs 110 pounds, develops on brake 15.7 horsepower at 2,000 revolutions per minute and is not of the Knight type either, this being impossible, as the Knight type of motors is four-cycle. Mr. Britt continues, "Strange to say, all things are best under but one condition and to produce a motor that will be equally economical under all conditions will be a feat worthy of my best efforts." How simple. All we have to do is run our present motor at a constant speed at which it operates most economically, to obtain the very result Mr. Britt so much desired.

Again, he says, "I am surprised to hear that, when I thought it was well understood, that of all the gear systems, the internal gear was the least efficient." It is a serious thing to think sometimes. In order that Mr. Britt will know I herewith give the comparative efficiency of the different gears:

Spur gears, 95 to 98.1. Efficiency tests made by Westinghouse Mfg. Co., *American Machinist*, May 5, 1910. Internal gears, 94.7 to 97.9. Foot Brothers Wks., Chicago, Ill. Bevel gears, 71 to 84, Brown & Sharp Mfg. Co. Spiral 20 to 85, depending on angle of tooth, Brown & Sharp Mfg. Co. Worm and worm wheel, 45 to 90, depending on angle and lead.

Considering that an internal gear has 25 per cent. more bearing surface on teeth than spur gears, it is very evident that the internal is for the horsepower transmitted the most efficient of all, rather than the least.

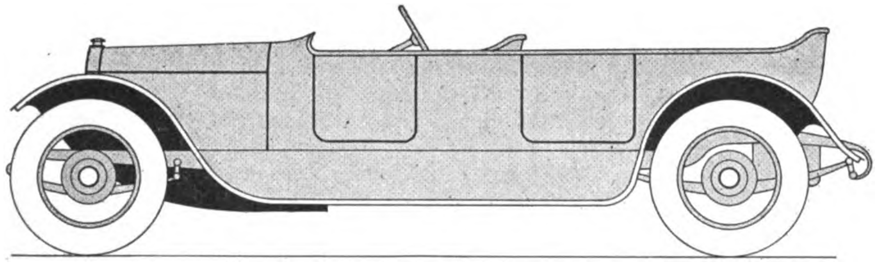
Mr. Britt then gives us the information that there is no difficulty in driving each wheel separately, but goes on to tell us we must have excessively heavy motors to do so; we must have, mind you, and here the Ingersoll Rand Co. and the Chicago Pneumatic Tool Co. are making air motors, developing 10 horsepower and weighing less than 50 pounds.

I presume I am still tantalizing Mr. Britt when I tell him that we have in use several thousand engines, of the Diesel, Secor and Hornby type, that do not use a carbureter at all.

In conclusion I will ask Mr. Britt to read a very interesting letter article on page 486 of the September 10 issue on the Two Stroke Cycle Ideal, which may help him digest this pill idea.—WILLIS A. SWAN.

A $1,000,000 Speedway for Minneapolis

MINNEAPOLIS, MINN., Sept. 26—Incorporation papers were filed last week in South Dakota for the Twin City Motor Speedway Assn., $1,000,000, of which Francis H. Wheeler, of Indianapolis, is president, and the company plans to have the first races on the new speedway near the famous Hamline dirt track July 4. Dr. C. E. Dutton, representative of the contest board of the A. A. A., is secretary of the company and is expected to manage the races. W. D. MacLeith, of St. Paul, is the architect. Meanwhile the Minnesota Motor Speedway Co., in which H. C. Moore, of Chicago, is interested, is selling stock with headquarters at the Hotel Dyckman.



The Rostrum

Wants to Eliminate Spark-Lever Misuse

EDITOR THE AUTOMOBILE:—There are so many drivers who use, or misuse, the spark lever that I believe a contrivance of the following description would eliminate the general practice of drivers of putting the spark lever three-quarters around on the quadrant, and leaving it there through all conditions of driving. Sit beside an operator and see how he handles the spark lever.

I believe that the spark should be advanced in direct proportion to the engine speed after a predetermined minimum retard and maximum advance. By this I mean a position where the spark should occur in the stroke of the piston when the engine is idle and also when delivering its maximum output.

Attached to a shaft on the engine, crankshaft, pumpshaft, etc., a solid or flexible shafting transmits the revolutions to a dial on the dash. This dial graduates from 0 to 20; 0 represents the engine idle or ready for cranking, spark fully retarded, and 20 the engine running at maximum speed, spark fully advanced.

The mechanism on the dash works exactly like a speedometer only instead of graduating the face in "Miles," graduate it in any desired number of parts. The combined number of parts equals the throw of the finger or minimum and maximum revolutions per minute.

The spark lever is now fully retarded and the spark set to occur in the stroke of the piston just as prearranged, and to also fire the charge, when the spark lever is fully advanced, at just that point in the stroke where we predetermined it was best practice when the engine is delivering its greatest horsepower.

Quadrant in Twenty Parts

The spark lever quadrant is divided into twenty or the same number of parts as the dial on the dash. It is not necessary to use guess work where the spark should be set, nor wait for a knock and then hurriedly retard the spark which is nine out of ten times retarded too far. Simply glance at the dial and set the spark lever opposite the number on the quadrant which the finger on the dial indicates.

I realize the automatic spark advance is ideal, but my contrivance costs a great deal less and still has the advantage of leaving the spark manipulation under the complete control of the operator. With the automatic spark there is a chance of the governor going out of commission, with good chances for a broken arm. At the least, faulty ignition would result.

You may answer me by saying that most of the later cars have self-starters. I acknowledge that, but there are very few cars that go an entire season without having to resort to the cranking handle snugly resting in some obscure corner of the tool box or under the seat.

Elmhurst, L. I. GEORGE W. GAY.

Deprecates Driving on Left

Editor THE AUTOMOBILE:—I inclose clipping from a recent issue of the Hartford Courant—read it—noting the portions underlined:

"George M. Landers, democratic candidate for lieutenant governor, had a run in late this afternoon with Fred N. Tilton, proprietor of the Atlantic Screw Works in Hartford—not politically, but automobilwise. Neither was hurt, although the circumstances were such that they considered *their escape from serious injury miraculous.*

"The traffic on the river road was unusually heavy and Mr. Landers's car was making slow progress. At the crest of a hill near the home of Cornelius B. Noyes in what is known as the Walkley Hill District, he hugged the side of the road to avoid a collision with a Ford car which was coming in the opposite direction and which Mr. Landers and Mr. Tilton aver, was taking up too much of the road. *Mr. Tilton, who had been traveling in back of the Ford car, was annoyed by the "road hogging" tendencies of the driver of the Ford car,* and turned his car to the left, as is the custom on the road in passing other cars. In doing this, however, he found himself confronted by Mr. Landers's machine. He tried to steer clear of the car and avoid going down a deep ditch, but was unsuccessful in getting by and struck the runabout so that the wheels of both machines were locked. The force of the impact was sufficient to put both cars out of commission, but not to throw them off into the ditch."

It interests you and everyone else connected with THE AUTOMOBILE. It is a sorry emphasis on the fact that many drivers of left-hand-drive cars do and will persist in driving to the left of the center of the highway.

In commenting on this fault I have exhausted all the choice brands of profanity I learned as a kid in the high school. I saw those two cars and believe me—talk about the Cathedral at Rheims—say—they were a sad sight, and it is a wonder no one was killed.

For the benefit of some of the good fellows who are driving the left wing of the Ford and allies, I wish you and others would nail to the mast of each editorial column the slogan—"Keep to the Right!" You'll agree with me it would go a long way to insure safety first.

Middletown, Conn. CHARLES H. COLES.

Use of Two Casings Unsuccessful

Editor THE AUTOMOBILE:—I notice in your issue of September 10, Mr. W. B. Duling's letter asking for others' experiences in using casings over other casings and wish to state that the writer has tried to get service out of old casings which were rim-cut and tread in good shape by putting same over another casing of which the tread was not so good, but have never been able to get casing to stay on for more than 5 or 6 miles, and would say that it is too much of a job to put casing on and inflate the other one every 5 miles.

If any of your readers have found a satisfactory way to keep outside casing intact, would appreciate hearing how it is done.

Gadsden, Alabama. L. C. KYLE.

Troubled With Slipping Clutch

Editor THE AUTOMOBILE:—I have a 1911 ——— model 30 roadster. It has a multiple-disc clutch which never fails to slip or let go entirely on a hard pull or any other pull after it gets warmed up. The oil splashes through from transmission to some extent, which has been taken into account in experimenting. No kind of oil, thick or thin, much or little, does any good. The only success comes from using heavy oil which makes it drag badly when cold and then slip when warm. The heavy oil seems to help hold the plates until warm, contrary to most disc clutches. All adjustments are all right and a stronger spring did not help. As you probably know, this clutch has given trouble on all cars of this model. The factory advised new discs, which helped for about a week, proving it is the slightly rough surfaces that tend to make the plates hold and roughening the plates is the temporary remedy practiced where these cars are in use. The discs in this clutch are about ten in number, 3-16 or 1-4 inch thick and about 6 inches in diameter. The front bearing depends on oil, splashed by the clutch for its lubrication, although a grease cup could be easily fitted.

There is no clutch brake. Will you kindly give me your opinion on the following:

—1—Will it help this clutch to double the number of plates, using thinner ones, of course?

2—Should alternate steel and bronze be used?

3—Could all steel be used?

4—Can you suggest any other probable remedy whatever?

Olympia, Washington. IVAN L. CREED.

—Your clutch trouble is probably due mainly to worn out disks, although there may be other difficulties also. One or more new disks should be added to compensate for the wear.

It is also of great importance to use a proper lubricant. A heavy oil is not desirable, but you should use a mixture of kerosene and a light lubricating oil. One-third kerosene and the rest lubricating oil is recommended.

1—We would not advise you to use double the number of plates but to just add one plate. The clutch does not need surface, but the slipping is due to the fact that on account of wear in the plates not enough pressure can be produced by the spring. This can be overcome in the manner suggested, namely, by putting in another disk.

2—Alternate steel and bronze disks might give better wearing qualities, but as already stated there is no necessity in putting in more than one new disk.

3—This is answered in two.

4—This is answered in the first paragraph.

Explanation of Cone Clutch Operation

Editor THE AUTOMOBILE:—Will you please explain the working of the cone clutch? Illustrate it if possible.

Canton, Ohio. R. EDWARDS.

—1—A typical cone-clutch construction is shown in Fig. 1. One member of the clutch is the flywheel itself and the other is the clutch spider which in this case consists of a sheet steel stamping faced with leather. The spider is made to rotate with the flywheel by forcing it against it by means of the coil spring shown.

Should Use 1-Inch Carbureter

Editor THE AUTOMOBILE:—1—What size carbureter should a person have for a 3 1-2 by 4-inch four-cylinder engine? I am using a model L 1-inch Schebler and I have tried every way to adjust it so that the cylinders will all hit on load, but as soon as I pull the throttle open it begins to miss. I have had new rings in, the valves ground and have had the best here to try and adjust it, but cannot get it any better. I even sent it back to the factory and had all new parts put in thinking that they might have done something to it in the garage they ought not to have done, but still it is no better.

Portsmouth, O. J. HOWARD SUTTON.

—1—A 1-inch carbureter is correct for your motor. Possibly the mixture should be heated or there is a leak in the intake manifold. Also inspect the ignition system carefully. See that the spark plugs are cleaned, in good condition and the gaps 1-32 of an inch. All insulation should be good, all connections tight, and no short circuits. The breaker points should be in proper adjustments and all brushes should make good contact and contacting surfaces should be clean. It is possible that there is a short circuit or a loose contact in the switch.

Points in Overhauling a Car

Editor THE AUTOMOBILE:—Will you please tell me what to do to overhaul my car? I have a general idea as to how the work should be done, but I want to make sure that I do not miss anything and would also like advice on any work that I may not be thoroughly familiar with.

Mt. Vernon, N. Y. H. W. F.

—A book could be written on this subject, but we will try to cover the main points briefly.

There are three considerations of prime importance in overhauling a car; thorough cleaning, adjustment of parts for wear and replacement of parts which cannot be adjusted.

Flush Cooling System

Under the first heading comes the flushing of the cooling system to remove any grit or dirt that has collected. At the same time, it should be noted whether there are any loose pieces that might obstruct the passageways. Grease and dirt in the cooling system may be removed by using a solution of washing soda in hot water. Stir in as much washing soda as will dissolve. It is not advisable however, to allow this solution to come into contact for any length of time with the aluminum parts. Spark plugs should be carefully cleaned, the carbon removed from the cylinders and the motor should be flushed with kerosene to remove any gummed oil.

Clutch Cleaned

The clutch facing should be cleaned with kerosene and if it is of leather, it should be soaked in neats-foot oil to soften it.

The gearset should be thoroughly cleaned. This is especially desirable because during the operation of the car a certain amount of grit collects from the lubricant. The same advice applies to rear axle and wheel bearings.

The various wearing parts should be adjusted or replaced depending upon how badly they are worn and whether any adjustment is necessary. The amount of wear that is allowable depends somewhat on the parts. If it is enough to be noticeable when shaken by hand, they should be adjusted or replaced. For instance if there are shims between the caps and the connecting-rod ends, one or more of these should be removed as required,—or if not, a slight amount of material should be removed.

Care must be taken, however, not to draw these caps up too tight. This advice applies to all other plain bearings. Where

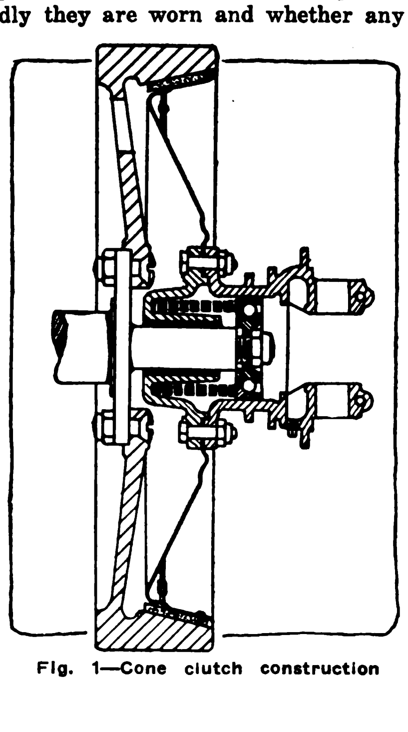


Fig. 1—Cone clutch construction

a bearing is badly worn, sometimes this adjustment will not be sufficient and the bearing will require rescraping. This, however, should be done by a man who has had experience.

Some types of ball and roller bearings are adjustable, while others are not. Cup and cone ball bearings can be adjusted and also conical roller bearings. Care must be taken, however, in adjusting these bearings not to draw them too tight. They should be just tight enough so that there is no play but not so they will bind.

The adjustment of the steering gear depends largely upon the type used as in other adjustments, it should only be made tight enough to remove the play. The brakes should be drawn up as tightly as possible and yet not enough so that they will dry.

The valves should be ground to remove the pits, and after this is done the push rods adjusted until there is about 1-100-inch clearance between every valve stem and push rod.

Valve Caps Are Stuck

Editor THE AUTOMOBILE:—I have an E. M. F. 30, 1912 model, and started to overhaul the motor, but found the caps over the valves were put in with white lead on the threads, which is so hardened that it is impossible for me to remove them. Can you suggest some method for removing these without breaking them?

Akron, Ohio. LOUIS GIEBEMATH.

—This is an unusual difficulty. Soften the white lead, if possible with kerosene, or oil, and if this will not loosen them up, force will have to be exerted. You should be able to start them with a cold chisel and a hammer.

Information on 1910 Cadillac

Editor THE AUTOMOBILE:—1—Kindly inform me how to determine when the front wheels are out of alignment? Also what can I do to straighten them up?

2—If the axle knuckle is bent, should it be heated? Should it be allowed to cool naturally, or must it be tempered in water? And how long?

3—What causes my car to jerk or miss? When starting it runs all right on first and second speeds, but so soon as I go into third or high gear it starts to run in a jerky manner. If I go back into second speed and push on the accelerator a little to give the engine more speed, for about half a square, and then go into third or high speed it will run all right.

My car is a 1910 Cadillac, in good condition. The spark plugs are clean and spaced correctly. The magneto was cleaned and adjusted and timed by a Cadillac man. This instrument is a Splitdorf low tension. Would this trouble come from the magneto and coil or carbureter? I have a new model K. Schebler carbureter, put on about six months ago. I have tried both rich and lean mixtures, but with the same result. This trouble has not been evident during the past week. Do you think it was the mixture, magneto or coil?

4—At this time of year should the air on the main intake pipe be heated by hot air pipes taken from around the exhaust pipe, or should the hot air pipe be disconnected? The auxiliary air is not heated.

Philadelphia, Pa. JOHN P. TULL.

—1—The alignment of the front wheels can easily be determined by measurement. With the wheels pointing approximately straight, measure the distance between the two wheels, at the front and rear. They should be ¼-inch nearer at the front, but not any more. The adjustment is made by shortening or lengthening the tie rod.

2—It is best to replace the axle knuckle if it is bent.

3—It seems most probable that the motor is missing or at least does not run smoothly at low speeds.

Adjust the spark gaps on the plugs to 1/32 inch, tighten all wiring connections, and look for short circuits caused by poorly insulated or bare wires.

See that the brushes on the magneto are in good condition and adjust the breaker points, if they need it. There may be a temporary short circuit in the switch at times.

Adjust the carbureter carefully. The air valve is for high speed and the needle valve for low.

Test the compression. It may be that the valves need grinding, or there is a leakage past the pistons or the valve stem guides.

4—It is better to heat the air all the year round.

White Steamer Boiler Clogged

Editor THE AUTOMOBILE:—I have a 1908 White Steamer, model K, and as you know the sides of the hood over the motor are ventilated. Here is where I made my mistake. I closed these openings to improve the appearance of the machine. On August 19, I made a trip to Palmyra, N. J., from Camden. After I had run two thirds of the distance, my engine overheated and stopped. I then opened these ventilators on side of hood, left it stand about 10 minutes and started off again, pumping oil to cylinders continually for about a mile. The result being, my boiler stopped, clogged, I think, from an excessive amount of oil. Can you tell me what will clean the boiler or remove the obstacle? The steam supply shut off instantly. I have used washing soda and lye. I can get a small quantity of water in the boiler by means of a hand pump.

Camden, N. J. ROBERT W. MAY.

—To overcome this difficulty, it is necessary to heat the part which has been stopped up and turn through it alternating sand and compressed air blasts. You had best go to the nearest White service station to have this done.—ED.

Valve Timing of Hotchkiss Motors

Editor THE AUTOMOBILE:—1—Kindly let me know the correct valve timing for Hotchkiss cars of the following types: 1905, motor type J; 1907, motor type T; 1914, motor type A D 6.

2—Where can I obtain a crankcase bottom for a 1915 type J, Hotchkiss motor, other than from Paris?

Roxbury, Mass. SAMUEL S. MARKOW.

—1—The actual time of the opening and closing of the valves of these models is unobtainable but if you desire to set the valves correctly, this may be done by bringing the piston, on one cylinder, 1-16 inch beyond top dead center. Then set the intake camshaft so that the intake valve in this cylinder is just ready to open. This applies to the J and A D 6 models, which have L-head motors. The T has a T-head motor and while the instructions given apply to the intake camshaft the exhaust camshaft remains to be set. This shaft may be timed without moving the pistons. Set the shaft so that the exhaust valve on this cylinder is at the point of closing.

2—It is impossible to obtain a crankcase for this model at the present time. We would advise you to have your present crankcase welded. If you have the facilities for doing this, proceed as follows:

The metal can be welded either with or without a flux, but it is preferable to do the work without one for the reason that the flux hardens the metal. The reason for using the flux is that it makes the solder more fluid and therefore it is a little easier to do the work, but when all the conditions are right and with a certain amount of experience the operation can be performed almost as readily without its use and with the result that a much stronger joint is formed between the edges of the members.

Before welding, the metal should be scraped and cleaned and if the stock is more than .25 inch thick, it is advisable to chamfer the edges. Pieces that are of such shape as to undergo strains when heated at the fracture should be heated all over by placing in a charcoal fire, using natural draft. The temperature should be between 300 and 400 degrees below the melting point. This can be determined in two ways. The heat should be sufficient to melt the solder stick or cause a drop of water to sputter on its surface.

When this is done remove the piece from the fire and cover it with asbestos sheets leaving an opening where the weld is to be made.

The oxygen acetylene flame should be reduced or softened by using an excess of acetylene to a degree that will be indicated by the extension of the acetylene cone to 1 to 1.5 inches beyond the white cone. This excess of acetylene does not injure the aluminum but merely lowers the flame temperature to the most desirable point. Sufficient pressure should be used on the torch to force the melted solder well through the fracture so that a ridge of solder will be formed on the other side.

An iron rod hooked at the lower end should be used to puddle the solder into the crack and this rod should be wiped frequently so that it will not become coated. After the joint is made the piece should be turned over and the ridge of metal on the other side should be smoothed off by means of the torch and puddle iron.

The secret of a successful weld lies in making thorough preparations and in doing the actual welding with almost feverish haste. The solder should be applied as soon as the piece is removed from the fire and if the application of molten metal to the crack is not continuous until the work is completed the joint will crack on cooling.

After the weld is made it should be covered completely to protect it against drafts and allowed to cool slowly.

Magneto Timing Advanced for Racing Cars

Editor THE AUTOMOBILE:—1—Is a magneto timed the same for racing as for touring?

2—How large a gap should the breaker points have and what determines the size of gap?

Sterling City, Calif. ELMER MARIAN.

—1—The setting of the magneto is generally advanced on racing cars, the amount depending somewhat on the speed of the motor and design of the magneto. It is quite usual to set the magneto so that the breaker points separate when the piston is 1-2 inch below top dead center.

2—The size of the spark gap depends somewhat on the magneto, the adjustment for different instruments varying between 1-64 and 1-32 inch. If the parts are adjusted so that the gap is too large the motor will not operate at slow speeds or at least will miss, while if the gap is too small missing will occur at high speed.

In the former case the breaker points either are set so that they do not touch at all or so that poor contact is made. This condition also occurs when the points become badly worn and jagged and this is the reason that when the magneto has been used for some time the motor will miss at slow speeds and it becomes necessary to smooth off the points and readjust them. This trouble is aggravated because the voltage generated by the magneto is at its lowest and for this reason the motor will run better on the battery, providing a dual system is used.

At high speed there are two factors to consider. If the gap is too small there is danger of the current arcing; that is, when the points separate a spark is produced. When this occurs the motor misses.

This is due to the fact that the voltage is greatest at high speeds and therefore while the arcing occurs under these conditions the points are not close enough together so that it will occur at slow speeds. It will not occur at slow speeds because the voltage is less.

Too large a gap may cause missing, for the reason that the inertia of the breaker arm is so great that the spring cannot bring the points together and close the circuit before the next break begins to occur. Furthermore, with the points far apart the hammering action is more pronounced and the points flatten out.

Companies That Manufacture Automobile Heaters

Editor THE AUTOMOBILE:—Do you think it is possible for automobile manufacturers to run a pipe line from the exhaust to small flat heaters on the floor to warm the cars in the winter? We appreciate the removing of the exhaust away from the floor for summer driving but it seems that heaters could be arranged at not a very great additional expense for the winter.

2—Do you think that the detachable top, such as the Kisselkar has, will gain favor?

Detroit, Mich. A SUBSCRIBER.

—1—It is not only possible to heat an automobile in the way you suggest but there are many devices on the market for this purpose. Among these may be mentioned the Four-In-One heater manufactured by the Auto Heater Co., of America, 1148 Bedford avenue, Brooklyn, N. Y.; The Garrison combined Heater & Muffler manufactured by the Garrison Gasoline Engine Specialties Co., 251 East Richmond street, Philadelphia, Pa.; The Radio Auto Heater made by the Milwaukee Auto Specialty Co., 715 Chestnut street, Milwaukee, Wis.

Hot water heaters that obtain their heat from the exhaust are made by the Peerless Radiator Co., Gibbs, Idaho and the Robinson Auto Heater Co., Milwaukee, Wis.

Foot warmers that employ a special fuel in the form of briquette are manufactured by the American Electric Co., State and 64th streets, Chicago, Ill., and by Lehman Brothers, 10 Bond street, New York City.

2—It is very difficult to give an answer to this question, because there are so many considerations affecting this.

Picric Acid Increases Power

Editor THE AUTOMOBILE:—As I remember, the racing cars, or even owners desirous of getting more mileage and power, use a certain amount of kerosene with picric or citric acid. Am a little hazy on this subject and will you please advise me what per cent. is used or whether the ingredients are as per the above. Or what is used for this purpose?

New York City. EVERETT WARD.

—Using picric or citric acid or ether in motor fuel gives a much snappier explosion and therefore more power. The proportion is about 1 pint of any of these to 5 gallons of gasoline. It is necessary, however, to keep the spark down. Racing drivers do not adulterate their gas this way as it is against the rules of the A. A. A.

Questions on Buick Model 21

Editor THE AUTOMOBILE:—1—Will you please explain how to adjust the bevel pinion and large bevel driving gear on the Buick model 21? W. R. C.

New York City.

—1—The beveled gear on this model is adjusted as follows: First remove the small plate on the axle housing back of the pinion. This gives access to a nut which may be turned to the right or left as desired. Tightening this nut will force the bevel closer to the crown gear and thus compensate for the wear.

The Engineering Digest

System for Choosing Gear Speeds and Securing Easy and Natural Shifts Under All Conditions

STRONGLY FAVORING HOGBACK POWER CURVES

ENGINEER F. ACHILLES, of Mannheim, Germany, advances the following new viewpoints with regard to the simplest method for determining suitable proportions among the different gear speeds of a motor vehicle:

Usually the idea of horsepower as a unit dominates when the work of an internal-combustion motor is under consideration, but for the present purpose something is gained by analyzing the work output of the motor more closely and mentally dissolving the horsepower unit into its constituent elements, force and velocity. Fig. 1 serves to keep before the mind the great difference which exists between the so-called theoretical power curve, which is a straight line based on an assumed proportionality of power and number of crankshaft revolutions per minute, and the curve showing the power which can be actually delivered; also the difference between the theoretical curve representing either force or torque as being independent of motor speed and therefore as a straight horizontal line and, on the other hand, the actual torque curve, which drops considerably toward the high-speed limit of any given motor.

From the torque available at the crankshaft it is easy to determine the curve representing the forward pull at the rim of the driving wheels for any one of the gear speeds, with a given diameter of driving wheels as well as a given direct transmission ratio determined by the bevel gear proportions. This is done in Fig. 2 for three assumed total gear reductions, and the drawing serves to fix in the mind those actual relations between the motor power curve and the different curves representing the pull at the wheelrims, which are of importance for the choice of the intermediate gear proportions.

It is first noticed that the maximum wheelrim pull occurs at a certain motor speed and drops off more or less rapidly with either increasing or decreasing number of revolutions.

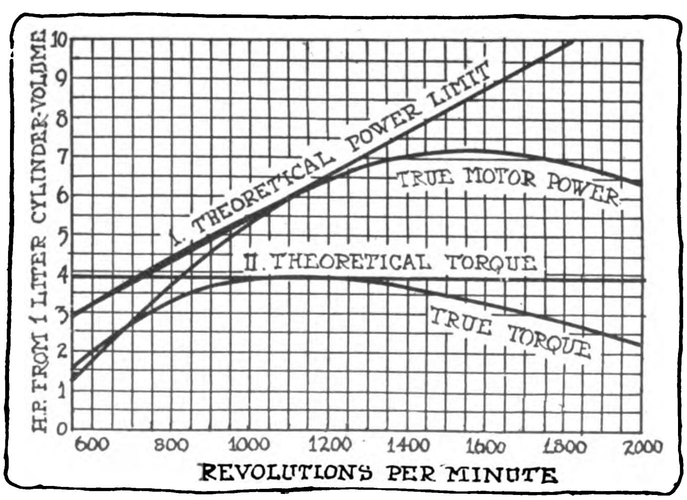

Fig. 1—The first elements determining driving comfort

Turning to the motor power curve, it is seen that it rises when the speed giving the highest wheel pull is exceeded and then again declines, first to the same level as at the speed giving maximum wheel pull and still more at further increase of speed. The efficient range of the motor is therefore naturally limited to the zone between the speed giving maximum wheel pull and the higher speed giving the same power but a considerably smaller pull. The two verticals in Fig. 2 indicate the limits of this zone. The meaning of these relations is clearly that at the low-speed limit of the efficient range strong traction power is available at low vehicle speed, while at the other limit only a smaller traction resistance can be overcome at the higher vehicle speed. In the operation of a motor vehicle it follows that the vehicle runs fast, when the traction resistance is small, on any given

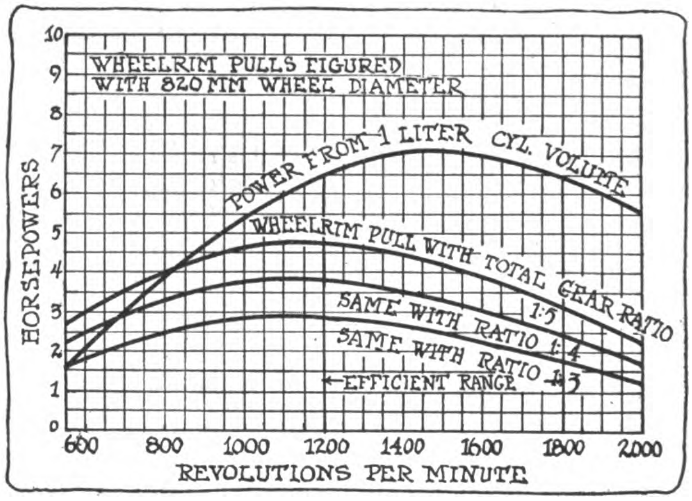

Fig. 2—Type of power and torque curve relations making for continuity of vehicle speed

gear, and the motor speed high, and that, if the resistance increases, both motor and vehicle slow down until finally the required wheelrim pull equals the maximum pull for the gear that is in mesh. Then it becomes desirable to shift to the next gear under such conditions that the reduced pull at the upper efficiency limit of the new gear suffices for overcoming the existing resistances by means of the higher motor speed coupled with the greater gear reduction. If it is now demanded that the available pull at the high limit of the new gear shall correspond with that obtained at the low limit of the previous higher gear—and this is the condition for smooth continuity in the driving conditions—then the proportion of the two gears must be chosen equal to the proportion between the wheelrim pulls at the two limits of the efficient range.

As, on the other hand, the traction resistance depends upon the vehicle speed, the demand should be made that no change in vehicle speed shall occur by reason of the shifting of the gears, in order that no sudden change in the required wheelrim pull may result. From this follows the second condition for a correct choice of the gear proportions; namely, that the total transmission ratios on the different gears also must be in the same mutual proportions as the motor speed figures at the two limits of the efficient range.

Altogether it is thus to be observed:

The proportion between two successive gear speeds must be chosen so as to be exactly the same as that between the available wheelrim pulls at those limits for effective operation of the motor the numbers of revolutions for which stand inversely in the same proportion as the wheelrim pulls.

This can be expressed more easily in the formula:

$$\frac{U_1}{U_2} = \frac{Z_2}{Z_1} = \frac{n_1}{n_2}$$

in which U signifies the total transmission ratio, Z the wheelrim pull and n the number of revolutions.

If the gear speeds are chosen so as to stand in these mutual relations, the motor must always work efficiently, and uniform transitions, accommodating themselves to the force and vehicle speed of the previous gear, will be obtained. And wherever in practice the gear proportions have not been chosen on this plan, the motor will automatically tend to adjust itself to the same manner of operating, unless a throttling of its power is the result, with the accompanying less profitable utilization of its possibilities.

When the two limits of the efficient range have been determined in accordance with this plan, and one turns

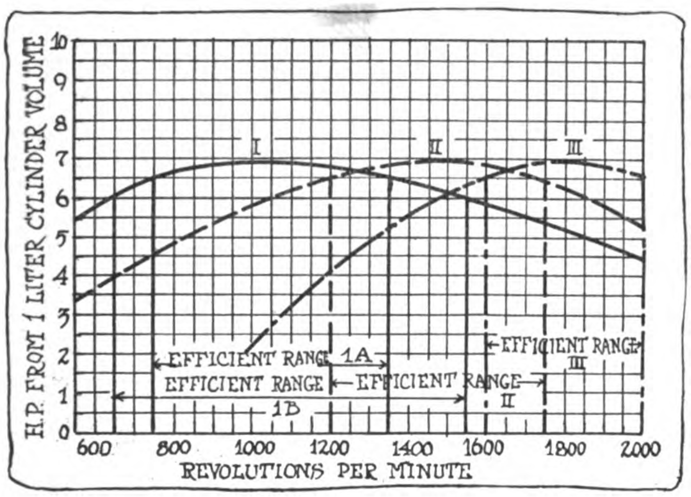

Fig. 3—Illustrating effect of motor type on gear ratio

again to examine the brake-power curve in this connection, it becomes plain that the power output always must be the same at these two limits if the wheelrim pulls are to be inversely proportionate to the motor speed figures. This would naturally be supposed to be the case, but it follows also from the equations expressing values for the wheelrim pull at the two limits, for a total transmission ratio X. For the lower limit this equation is: $Z_1 \,.\, X = \frac{716\, N_1}{n_1}$

and for the upper limit $Z_2 \,.\, X = \frac{716\, N_2}{n_2}$

[These are derived from the basic formula for deriving torque from horsepower:

$$M = Pr = \frac{60 \times 75\, N}{2\pi}\ \frac{N}{n} = 716.197 \frac{N}{n}$$

in which M is torque, N horsepower, P brake pressure in kilograms, r the radius in meters, n number of revolutions. Z in this case of course corresponds to M.—Ed.]

It is seen by dividing the first by the second equation that to have $\frac{Z_1}{Z_2} = \frac{n_2}{n_1}$, horsepower N_1 must equal horsepower N_2.

The range of motor speeds to be utilized is therefore determined by limits at which the horsepowers, N_1 and N_2, are equal, as in Fig. 2.

This is illustrated by examples in Fig. 3. The slow-speed

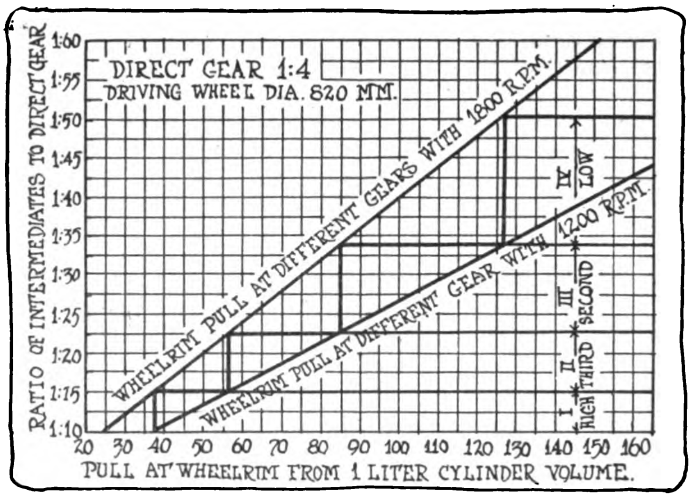

Fig. 4—Chart for ascertaining car's road ability in advance

motor represented in brake-power curve I is to be utilized in one case with a minimum output of 6.5 horsepowers per liter of cylinder volume. The motor speed limits lie then at 750 and 1,350 revolutions, and the efficient range is that marked I. A. The proportion between these figures is 1.8, and the division into gear speeds must be made with this factor. In the case indicated by the efficient range I. B the same motor is to be utilized down to an output of 6 horsepowers, and the range of motor speeds must accordingly be extended from 650 to 1,550 revolutions per minute. The proportion regulating the gear speeds consequently becomes 1,550 divided by 650, or 2.38.

The medium-speed motor represented in curve II when utilized above 6.5 horsepowers ranges from 1,250 to 1,750 revolutions per minute and requires a proportion of 1.46 in the gears, while curve III of a high-speed motor, ranging from 1,600 to 2,000 revolutions, calls for gears proportioned with a progressive factor of only 1.25. [The diagram is slightly misleading by ignoring the difference in power which would be expected from 1 liter of cylinder volume in three motors of very different speeds, but for mere illustration purposes this discrepancy is evidently not essential.—Ed.]

In this connection there is yet to be observed that the lower limit of the motor speed range must not extend beyond the peak of the wheelrim pull curve. On the contrary, to be assured of sufficient power at a gear change to maintain the vehicle speed unchanged, the wheelrim pull curve must decline steadily from the low limit toward the high limit of motor speeds.

In accordance with all the foregoing, the method of choosing the gear speeds for given conditions is now characterized by the following proceedings: (1) Tracing the power curve of the motor from brake tests, (2) constructing the curve of the wheelrim pull or torque according to the total transmission ratio—equal to that of direct gear—and the diameter of driving-wheels, (3) determining the number of motorshaft revolutions at which maximum driving torque is obtained, and (4) choosing the low-limit motor speed, preferably a little higher than that giving maximum torque, whereafter the high-limit motor speed is chosen at the number of revolutions beyond the power peak giving the same power as the low limit speed. The proportion between these speed figures is the proportion to be incorporated in the gears to obtain continuity of vehicle speed with varying traction resistance. If this proportion is changed, the range of motor speeds to be utilized is changed automatically in practice.

An example may be taken from Fig. 2. The efficient range there lies between 1,200 and 1,800 revolutions, the wheelrim pulls with the assumed transmission ratio of 1 to 4 amount to 36 and 24 kilograms respectively, the power at both limits at 6.5 horsepowers, and the proportion 1,800 : 1,200

= 36 : 24 = 1.5 : 1 must also be that of the gear ratios.

Assume that the proportion in gear ratios is chosen 1.4 : 1 instead, then the utilized range of motor speeds will be changed to from 1,240 to 1,740 revolutions and other values correspondingly. If, to get the extreme maximum of wheelrim pull, which is obtained at 1,150 revolutions, the low limit is placed at the same point, the other limit will be extended to 1,850 revolutions, and the factor of gear progression will become 1.6 : 1. Are thus the two limits determined, the available wheelrim pulls can be figured out and consequently also the maximum grades which the vehicle will be able to climb on each of the gears, if the different traction resistances are also considered. To this end it is only necessary to chart the wheelrim pulls according to their values for each of the gear speeds, as is done in Fig. 4.

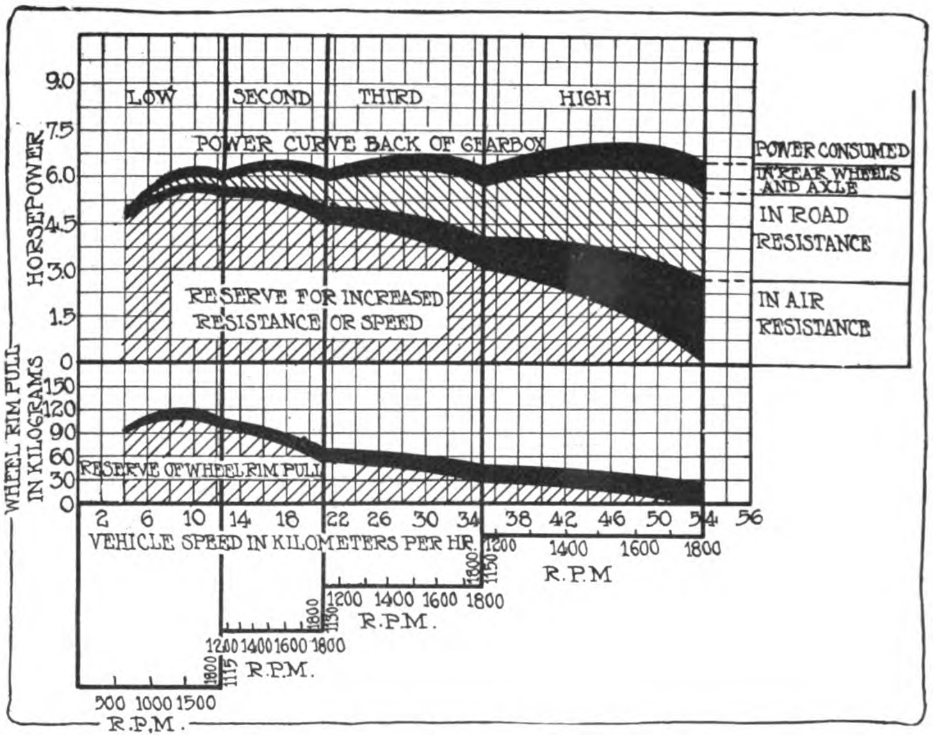

Fig. 6—Image of complete driving conditions with proper gear ratio

The plainest moral of the foregoing lies in the evident influence upon the gear proportions of the brake-horsepower curve. The motor designer must draw his inferences from these relations. From the presentation so far made the motor designer will be able to perceive offhand what range of the power curve in reality can be utilized in the driving of a car. It cannot be the object to design a motor so that it will produce power at a rate which continues to rise with increased number of revolutions. The important thing, on the contrary, so far as driving-results are concerned, is to get the maximum power development well within the limit of motor speed, the latter being first determined according to constructive and other requirements—in other words to get a hogback power curve. It can be secured by adjustment of the carbureter.

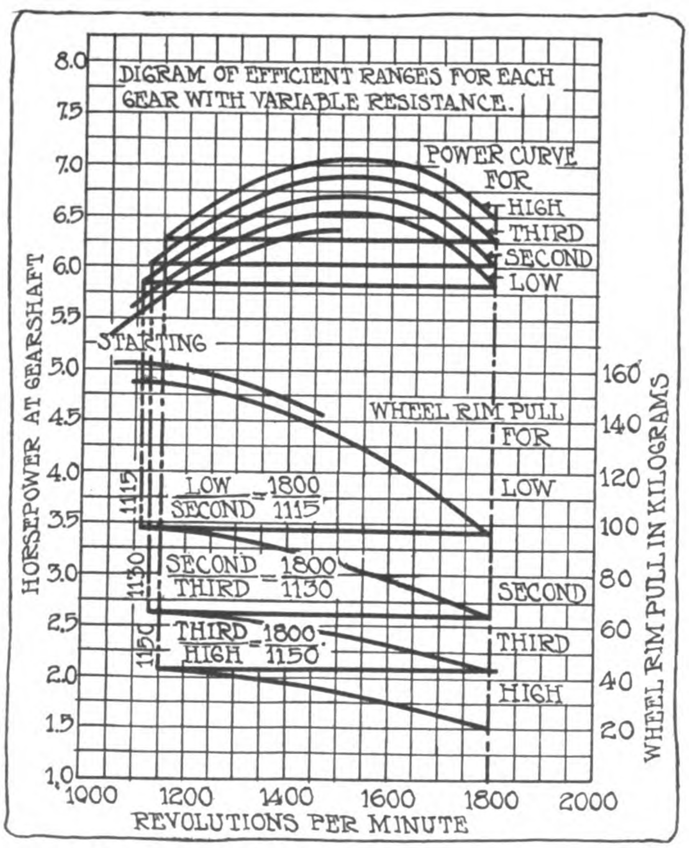

Fig. 5—Illustrating allowance for variations in transmission efficiency

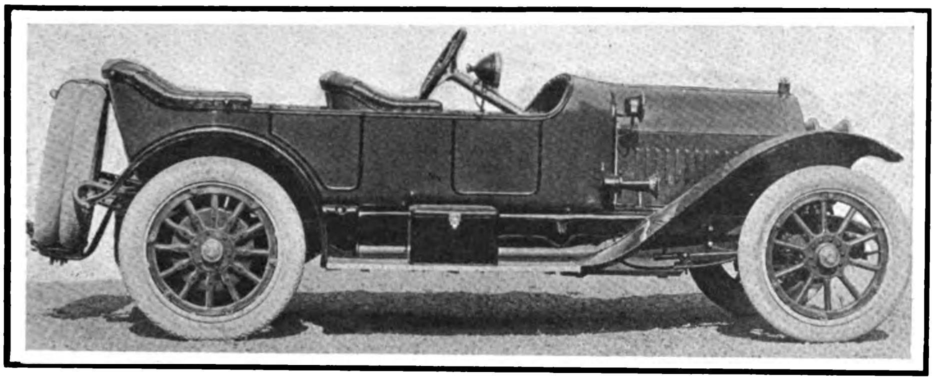
With regard to the influence upon the gear proportions of the efficiency curve of the vehicle as such, it is notable that it is only changes in the driving-resistances which are taken care of by a change of gear, and these depend only upon the movements of the vehicle. For this reason, to determine the gear proportions it is the power output at that point in the transmission system which must be considered where the power losses cease to depend upon the motor speed alone and where the resistances to be overcome begin to depend upon the vehicle speed alone. The point in question lies always back of the gearbox. The power curve to be used is therefore the brake-power curve minus resistances in gearbox.

In most cases it should be sufficient to assume a constant loss for all the gears. Minor variations occur, however, as between direct gear and the spurwheel transmissions, and such variations can be taken into account by choosing the proportion between two successive steps of the corresponding power curves to coincide with the proportion between the motor speeds at the upper limit of the lower gear and at the lower limit of the next higher gear, both of which give the same power. In this process certain rules may be adopted with regard to the limits of the efficient range. It can be established, for example, that the motor must not exceed a certain maximum speed. Then the curve for the first gear, by which the ratio is fixed, is determined by the identical power output required at the beginning of the next gear. On the other hand, it is also possible to start the curve from a different number of revolutions for each of the gears, with due consideration of the location of the maximum torque. In Fig. 5 there is given an example of this manner of laying out the gear proportions with allowance for the difference in the transmission efficiency for each of the gears.

All in all, the viewpoints presented for the selection of gear proportions seem to take all conditions of interest into definite account. A continuous image of the practical effects and the transportation movements resulting from the application of the method to a definite set of vehicle conditions has been constructed in Fig. 6, and may stand as an example of what may be done in other cases by introducing the values proper for each.—From *Auto-Technik*, April 11.

Small Four Runabout Is Newest Stutz



Stutz bull dog, a four-passenger body on the large four chassis

Also Light Four-Passenger Body on Larger Four Chassis —Small Four Has Block Motor

TWO new cars have been added to the Stutz line, one an entirely new model with a different design of motor mounted on a smaller chassis than any yet put out by the Stutz company. The other is a four-passenger speed body, placed on the same chassis that has heretofore been fitted with the Bearcat and roadster bodies.

The new small four is entirely typical of its manufacturer in every particular save for the L-head motor which marks the first departure of the Indianapolis concern from T-head practice. Another departure is that the cylinders are cast in block, whereas in all former Stutz cars the four cylinders were cast in pairs.

New Torque Tube Support

The use of block cylinders has enabled the designers to considerably shorten the chassis, cutting the wheelbase down to 108 inches, whereas the Stutz Bearcat is 120 incnes.

Another change that has been made to accommodate the shortness of the chassis is in the connection of the forked yoke of the forward end of the torque tube. Instead of having this connection made to a cross frame member a face plate has been bolted over the rear end of the clutch housing and the connection of the torque yoke made to that.

In all other particulars the features that have characterized Stutz design in the past have been maintained. The clutch is a cone, power transmission is through a three-speed gearbox, the rear system is a Stutz, the front axle Timken and the drive and control are on the right. The selling price of this new four, which is known as the H. C. S., is $1,475

It is built only as a speedster and although not fitted with a top or windshield it is ironed for the former and can be fitted with the latter if desired. Speedometer and Hartford shock absorbers are mounted on this car as regular equipment as on all models. The completeness of equipment is a feature.

The other new Stutz is known as the Bulldog. It is also a speed model and is mounted on the same chassis as the Bearcat. In fact, it is the same as the Bearcat in every particular except that the body is a four-passenger one and while the Bearcat is supplied in both four and six cylinders the new model only comes as a four. The price is $2,250.

Being a speed model, neither top nor windshield is fitted to the Bulldog. The body is low-hung with high flush sides allowing the passengers to sit low.

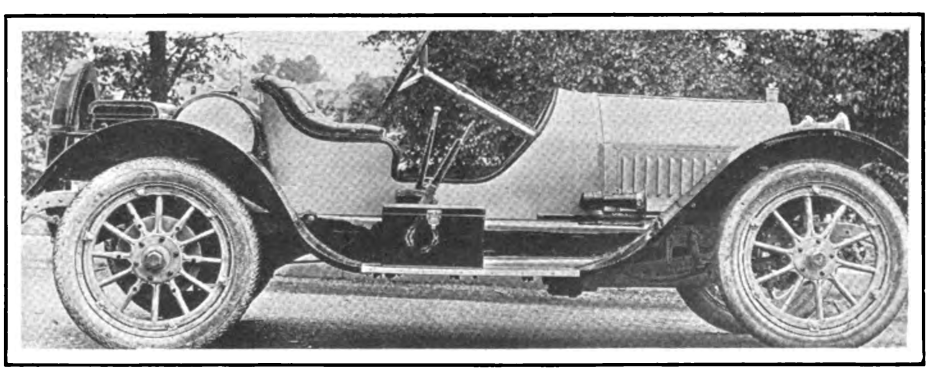
With the addition of the two new models the line has been brought to a point where the purchaser has a choice of ten cars.

On the 130-inch chassis there is a six-passenger touring and a six-passenger sedan. Outside of the choice of two bodies on this chassis the purchaser has his choice of a six- or four-cylinder motor. The two motors are interchangeable the bolt holes for anchoring the four-cylinder motor to the chassis are in the same positions as those which hold the six. This choice of two motors and two bodies gives a selection of four cars of 130-inch wheelbase.

On the 120-inch chassis the purchaser has a range of five cars. In the Bearcat model, which has been one of the Stutz leaders for the past 2 years, the same option of four or six cylinders is offered as on the larger chassis. The motors are also interchangeable and the parts throughout are designed to take care of the needs of the six-cylinder motor. When the four-cylinder motor is fitted there is no great difference in power as the difference in cylinders is made up by the larger bore and stroke of the four. The roadster is also made in fours and sixes and the Bulldog only in fours.

The tenth model is the last to be introduced to the line and, in fact, the Stutz company has only just commenced to ship them to its dealers. This is the H. C. S. It is intended for that class of purchaser who desires a speedy roadster of light weight. The prices of the ten models are as follows:

Model	Wheelbase	Cylinders	Price
Touring	130	Six	$2,400
Sedan	130	Six	3,800
Touring	130	Four	2,275
Sedan	130	Four	3,675
Bulldog	120	Four	2,250
Roadster	120	Six	2,125
Roadster	120	Four	2,000
Bearcat	120	Six	2,125
Bearcat	120	Four	2,000
H. C. S.	108	Four	1,475



Small Stutz roadster selling for $1,475

Like all the other Stutz cars the small four is equipped with a Wisconsin motor. In this instance a block-cast, power-plant with L-head cylinders marks a change from the former cars bearing this name. The valves are on the left and are covered by two removable cover plates held in place by knob screws.

Integral Intake Manifold

The new engine differs from previous motors used by the Stutz company in that it is a high-speed type of fairly high stroke-bore ratio. The bore is 3.75 and the stroke 5 inches, giving a stroke-bore ratio of 1.33. The casting is exceptionally compact including the water intake manifold and the inlet as a unit. The gases before entering the cylinder are preheated in this manner, both by the water from the radiator and by the heat radiated through the walls of the casting. The exhaust manifold is cast separately.

The cooling system is thermo-syphon, whereas on all the other Stutz cars the water is pump-circulated. On the H. C. S. engine the water outlet manifold rises through a bolted-on header from the cylinders and the waterjackets are large to give the free-flow demanded by this system of cooling.

Oiling is force feed with the oil pumped from the reservoir in the base of the engine to the three main bearings and through the hollow crankshaft directly to each of the crank bearings. It is then thrown off into the cylinders in the form of a spray that maintains a supply of lubricant in the motor.

Ignition and Lighting in One

It is in the electric equipment of the car that another noticeable change has been made. Instead of the combined starting and lighting unit with a magneto for ignition, the two-unit idea has been kept and a combined unit used for lighting and ignition with a separate starting motor. The starting and lighting equipment is manufactured by the Remy company as in the past. The lighting-ignition generator is mounted on the left side of the motor and the cranking motor at the rear right meshing with a gear on the flywheel only when needed to start the engine. The cranking motor is a simple series design capable of spinning the engine under normal conditions at 100 revolutions per minute.

As the H. C. S. is only made in the speedster design with a large cylindrical gasoline tank mounted behind the seat, the gravity system of gasoline feed is employed. The carbureter is the Stromberg G. 1-inch size. It is fitted with hot-air intake.

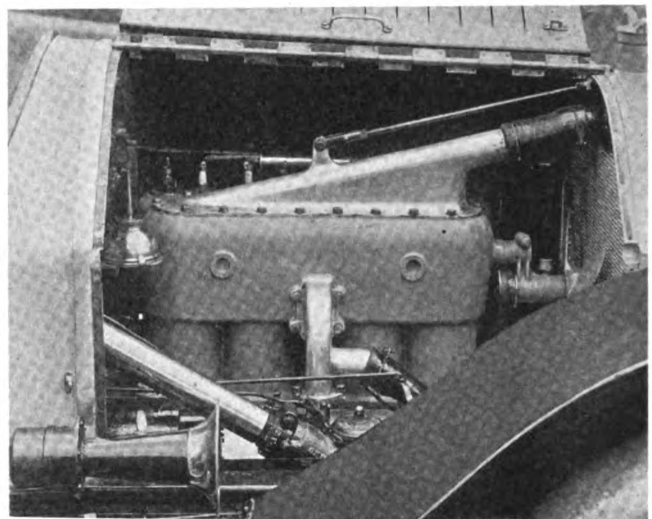
A leather-faced cone clutch with spring inserts beneath the leather is employed. The clutch pedal, as well as that for the brake, has an adjustment feature by means of which the length is adjustable. The entire variation in the length of the pedals totals 2.5 inches. Behind the clutch housing is bolted the face plate which takes the forked end of the torque tube as previously mentioned.

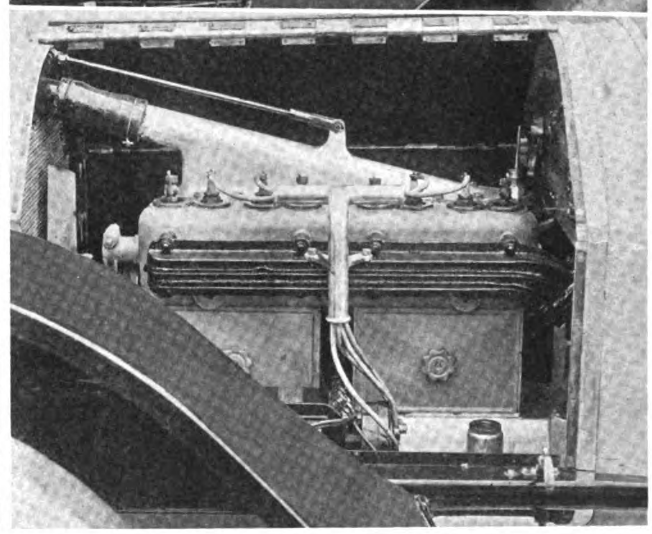
Gearbox on Rear Axle

The rear system employed in this car is the same as that which has formed a part of Stutz cars ever since they were introduced. The three-speed gearset is mounted just forward of the differential housing parallel to the torsion tube which incloses the drive shaft. While the forward end of the drive shaft runs on roller bearings, F. & S. annular ball bearings are used throughout the gearbox and on the outer ends of the axle shafts. The inner ends of the axle shafts are fitted with roller bearings of the tapered variety capable of taking the end thrust as well as the load.

The steering gear used in the H. C. S. is a Gemmer and in this particular the new car is similar to the older ones. Following Stutz practice the steering gear is mounted on the right and the control of the car is also on the right.

The brakes are double internal expanding operating on a drum bolted to the rear wheels. The wheels carry 32 by 4-inch tires. They are wood on the stock cars. The springs are semi-elliptic.





Upper—Right side of new small Stutz roadster known as the H. C. S. Lower—Left side of motor

The body resembles the Bearcat very closely. It is built along racing lines but instead of having the seat directly on the frame as in the Bearcat it is raised slightly above and there is a small sill which is a continuation of the downward sweep of the deep cowl. Although the body is ironed for a top none is fitted as the idea of the car is not to be used for a touring design but as a speedy raceabout. If desired, however, both a top and windshield could be fitted. The gasoline tank is carried on the rear deck and a trunk is fitted behind that. The spare tire is carried on the rear.

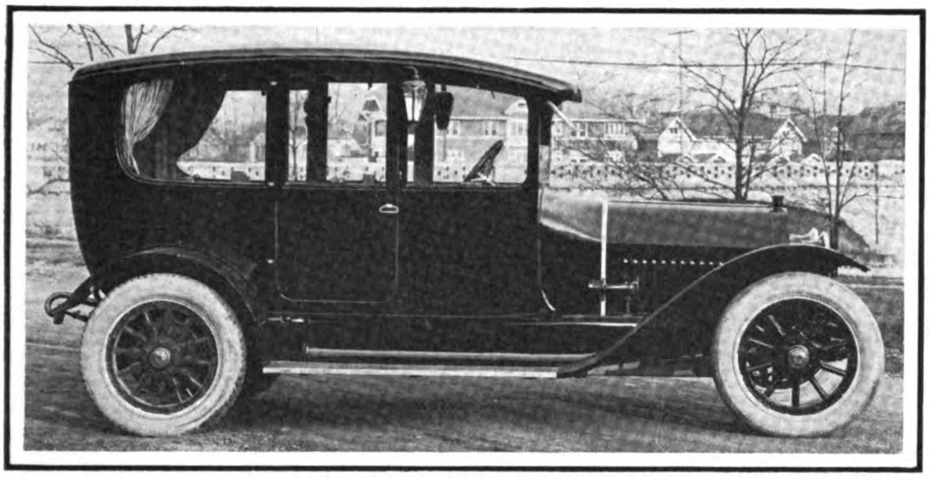
The 4.75 by 5.5-Inch Motor

The four-cylinder motor for the cars mounted on the 120 and 130-inch chassis is a T-head design with the cylinders in pairs and measuring 4.75 by 5.5 inches. The maker claims a horsepower of over 60 on the block at 1,500 revolutions per minute. The cylinders are offset .75 inch.

The crankshaft, .40 per cent. carbon steel, is carried on three main bearings. The push rods are roller type and the entire valve action is inclosed by an aluminum housing which is split in the center.

4 by 5-Inch Six Motor

The six-cylinder motor for the 120 and 130-inch wheelbase cars is of the same general construction as the four-cylinder except that it has a smaller bore and stroke, being a 4 by 5.



Stutz six-passenger sedan mounted on either a four or six chassis

The six-cylinder motor is also a T head and has the cylinders cast in threes. It has all the main features of the four, such as hollow crankshaft, force-feed oiling, large valves, and four-bolt connecting rods. The valves are inclosed by aluminum plates in the same manner as in the four-cylinder engines, except that instead of being held by a spring, the cover plate is removable by unscrewing a thumb nut.

The crankcases of both the four and six-cylinder motor are aluminum castings with the upper half supporting the main bearings by webs cast integrally and the lower half acting as a cover for the working parts and carrying the oil reservoir which in the case of the four has a capacity of 7 quarts.

Magneto Ignition Used

The lighting, starting and ignition equipment on the four and six-cylinder motors is similar. Ignition is accomplished on all fours except the H. C. S. by Bosch high-tension, double-type Z R magnetos, and on all the six-cylinder cars by Eisemann dual. This marks a change, however, from previous practice as some of these cars were furnished with low-tension magneto ignition.

The starting and lighting systems employed on the entire line except the new H. C. S. model as described, are the Remy motor-generator type. In these instruments the winding is such that below a certain speed the action is that of an electric motor while above that speed they act as a generator. On the average they start charging the storage battery at a car speed of about 15 miles per hour.

The clutch, gearbox and rear axle used on all these cars is the same in all essential details as that described for the H. C. S. model, the horsepower capacity of the transmission units being increased to take care of the greater strains imposed by the heavier and more powerful cars.

The tire sizes of all the cars on the 120-inch wheelbase cars are 34 by 4. On the 130-inch cars they are 34 by 4 for the touring in both four and six cylinders and 34 by 5 for the sedan. Wire wheels are furnished on these models at an extra cost of $100.

A wide choice of body colors is offered. The new H. C. S. comes in monitor gray, azure blue and Mercedes red; the Bearcat in gray, Mercedes red, vermilion and yellow; the roadster the same as the Bearcat; the new Bulldog, battleship gray with red upholstery. Azure blue with black or Mercedes red with red; the touring, ultramarine blue and maroon, and the sedan, ultramarine blue with Brewster green.

Model H. C. S.

Crankshaft diameter	1.75	inch
Rear crankshaft bearing length	4	"
Front and center bearing length	3	"
Big end bearing length	2.25	"
Piston pin diameter	1 3-16	"
Valve diameter	1 11-16	"

Prizes for N. Y. Automobile Parade

NEW YORK CITY, Sept. 27—The New York Commercial Tercentenary Commission has appropriated a fund of $10,000 for the automobile pageant to be run in connection with celebration on the evening of October 28. Of this amount, $5,000 will be in the form of awards, trophies and medals for decorated cars in the various divisions of the pageant.

William C. Poertner, who was recently asked to be chairman of the automobile committee, has retired in favor of J. E. Thompson. Merle L. Downs has been made secretary.

August Imports in N. Y. Port, 74 Cars

NEW YORK CITY, Sept. 28—The Custom House Statistical Bureau has published a detailed table of merchandise in bond on September 1, 1914, for the district of New York. This report states that seventy-four automobiles, valued at $146,610, were imported in the month of August, compared with seventy-eight automobiles, valued at $156,582, for the same period in 1913. Automobile parts imported were valued at $21,727 against $9,330 in 1913.

Smooth Exterior on New Eisemann

Single Magnets Used—Breaker Mechanisim Simple—Greater Factor of Safety—Hot Spark at Low Speeds

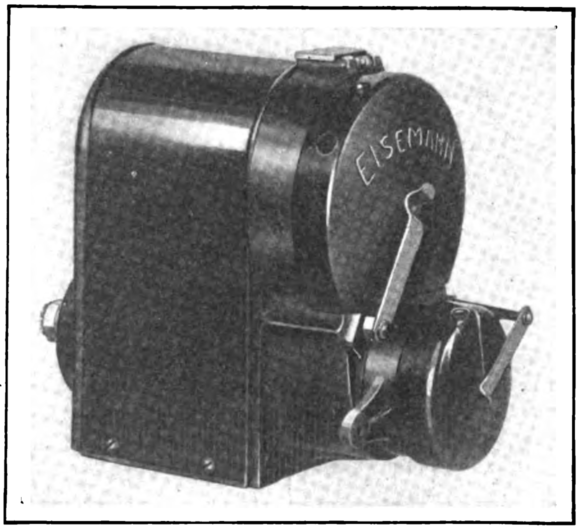

Fig. 1—Smooth and simple exterior of new Eisemann high-tension magneto

THE Eisemann Magneto Co., Bush Terminal, Brooklyn, N. Y., has placed on the market a new waterproof magneto which is styled type G and which differs in a number of respects from all other Eisemann magnetos. The new instrument is of the straight high-tension type, no provision being made for battery ignition. It is made for both four and six-cylinder motors of all sizes. It is chiefly remarkable for its extreme simplicity, the fewness of its parts and the intensity of the spark which is produced at exceptionally low armature speeds.

In appearance the new instrument is quite different from its predecessors. It is exceptionally smooth and compact. The magnets are covered by a sheet steel housing which is pressed into place in such a way that the joints are perfectly tight. The distributer housing is smooth, the terminal connections being inside. In fact the whole instrument is infinitely simpler in both construction and appearance than the older types of Eisemann magnetos.

Single Magnets Used

In construction the magnets are essentially the same as have been used in the past. Due to a more efficient winding of the armature, however, it has been found unnecessary to use double magnets. The distinctive Eisemann pole piece construction is retained. It is largely due to this that a strong, hot spark is obtained at very low speeds. The pole pieces themselves are in the form of wedges with their thickest parts at the center of the armature, as is shown by the accompanying illustration; consequently the armature is at no time isolated entirely from the pole pieces.

Magnetism Concentrated.

This construction causes the magnetic lines of force to be drawn from the extremities of the pole pieces toward the center of the core which results in the entire volume of the magnetic lines of force passing through the winding without being diffused. In addition this makes possible a somewhat wider range in timing the spark. Furthermore the armature acts as a keeper for the magnets and thus prevents their demagnetization.

Although the armature winding in the new instrument is practically unchanged, long experiment coupled with experience has produced a more efficient proportion between the secondary and the primary. At the same time the current collecting slip ring has been shifted to the end opposite to the end it occupies in other Eisemann instruments. This change has resulted in bringing all of the vital parts of the instrument to one end where they are all readily accessible by the simple expedient of removing the distributer housing and the breaker box.

Larger Safety Factor

In designing the new armature a much greater factor of safety has been allowed for. Instead of being placed between two closely spaced insulating rings, the slip ring R, Fig. 2, has considerable space between it and the insulating material at either side. At the gear end this insulating ring M is very thick and in order to obviate the possibility of the spark jumping to the gear in the case of a disconnected high-tension lead the insulating ring is deeply corrugated; thus its thickness is proof against the possibility of the spark piercing through and the corrugations prevent the spark jumping across the top.

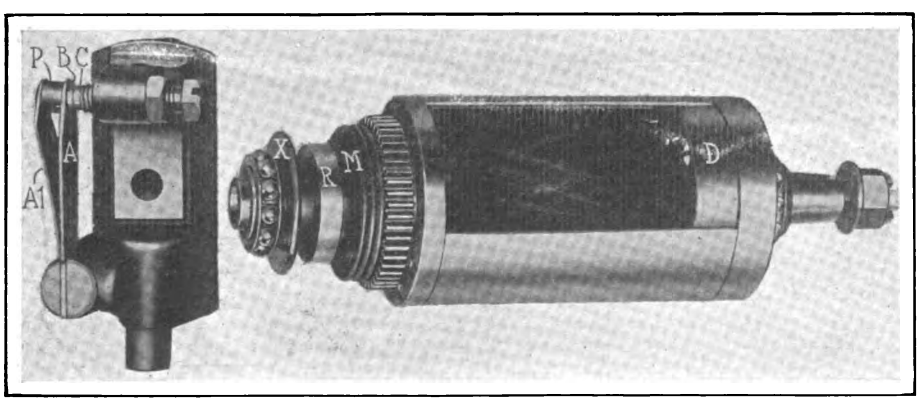

Fig. 2—Left—Detail of breaker mechanism. Right—Armature showing slip ring R and insulating rings M and X

The insulating ring X at the opposite side of the slip ring is similar in form to that ordinarily used but is slightly thicker and there is considerable space between it and the ring. The slight change in wiring has permitted the use of a smaller and more compact condenser which is housed in such a way that injury, except by direct intent, is practically impossible; otherwise the armature is standard, the core being built up of T-shaped castings pressed together with a quantity of laminations directly in the center where the magnetic influence is strongest. After winding, the armatures are shellacked and placed in an oven at 180 degrees Fahrenheit. This process is repeated three times, after which the winding is considered to have had the last vestige of moisture removed and to be impervious to water or oil.

The circuit breaker, Figs. 2 and 5, is entirely new. Instead of being a comparatively heavy arm, there is a very light spring A which carries one of the platinum contacts B and which rotates with the armature shaft; the other contact C is mounted in the part which supports the spring.

The auxiliary spring A1 is merely for the purpose of slightly increasing the pressure between the contact points; it is separated from the main spring by a fibre plug P in order to eliminate the possibility of trouble resulting from static conditions.

Made integral with the breaker box there is a small cylinder D with two fibre inserts E and a third felt insert F, the latter serving merely for lubricating purposes. As the breaker mechanism rotates with the armature, the spring A wipes alternately against the fibre inserts D and E, thus making and breaking the primary circuit. The simplicity of this mechanism is only one of its noteworthy features. As there are no bearings, it is impossible for wear to cause irregular firing and as there is nothing to stick, possibility of trouble on this account is positively eliminated. Another very valuable feature is that owing to the exceptional lightness of the parts there is no battering of contacts which, consequently, may be expected to wear a correspondingly longer time.

New Distributer

The distributer has come in for complete revision. As already has been noted, there are no connections outside. The high-tension leads enter tapered holes in the top of the distributer block, the stripped ends being wrapped around large threaded studs. Over the wire is placed a washer W, which is tabbed to prevent it from turning when the nut N

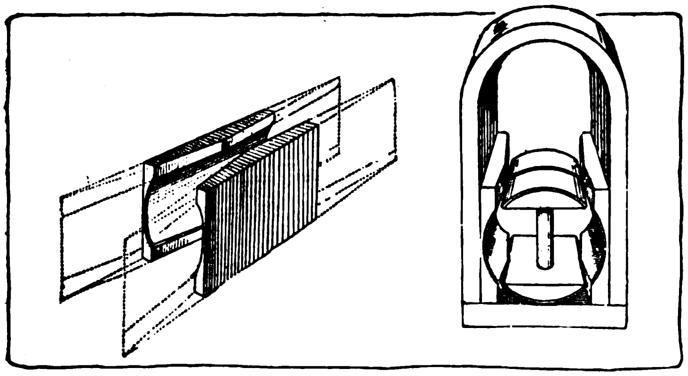

Fig. 3—Tapering pole pieces used to concentrate the lines of force

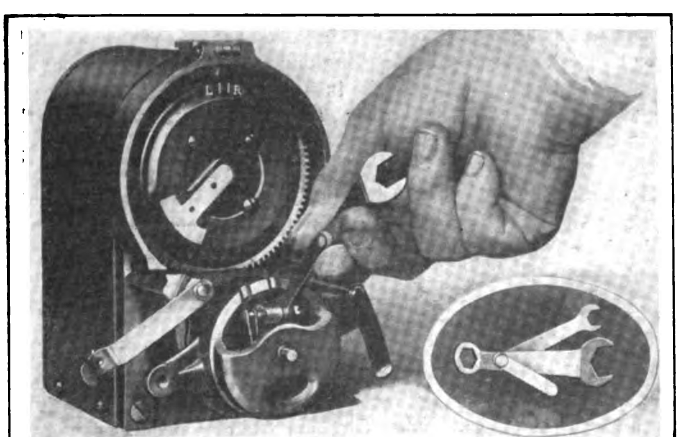

Fig. 4—Adjusting the breaker gap. A special wrench is furnished for this purpose

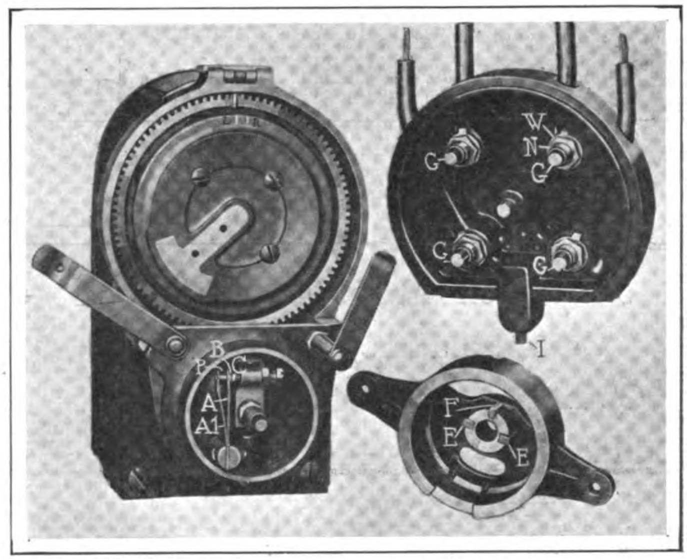

Fig. 5—Details of distributer and breaker construction

is screwed down. Before the leads are attached they are forced into their respective holes and as they are a tight fit it is impossible for moisture to enter.

The high-tension distributer contacts G as well as the ground connection H are carbon—light springs being used to insure perfect contact with the distributer arm.

The distributer arm is inserted in the disk with which it rotates touching in turn the high-tension lead contacts. The location of the current collecting slip ring in its present position has made possible the elimination of a large number of parts heretofore necessary. The current collecting brush I is mounted in the distributer block and is removed with it, exposing the slip ring when the block is taken off. This makes it unnecessary that the current be led from one end of the magneto to the other as has been the case in the past.

Another excellent feature of the new instrument is that installation and timing have been simplified to the greatest possible degree. On the distributer gear there are two marks, one for left hand engines and one for right hand engines. In timing the magneto it is merely necessary to place one piston in firing position and turn the distributer gear until one of the marks, depending upon the direction of the rotation of the crankshaft, is in line with a screw in the distributer covering.

Electrics to Set New Mileage Records

New York City, Sept. 28—For the purpose of demonstrating the possibilities of the modern electric vehicle, both of the pleasure car and motor truck types, the New York Electric Vehicle Association has perfected plans for the running of a series of mileage tests during the Electrical Exposition and Motor Show in New York, October 7th to 17th. These tests will be run on the board track, which is laid out each year on the third gallery of the Grand Central Palace, for the purpose of showing electric vehicles in action during the show.

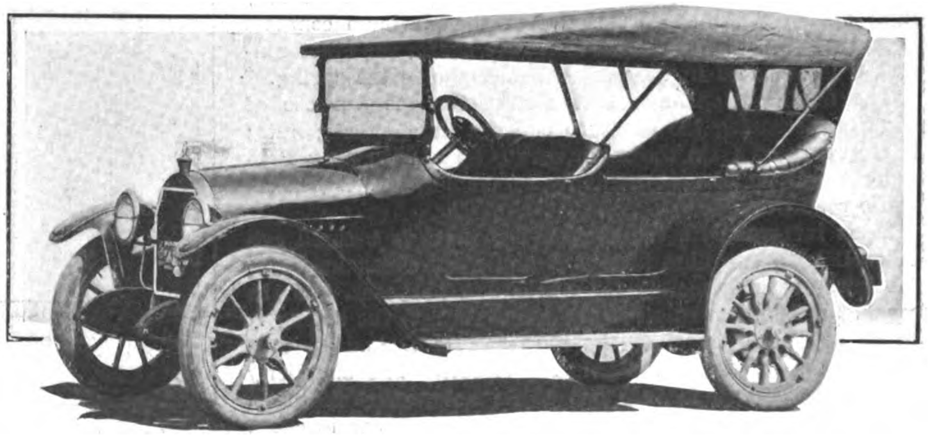
One of the tests will be for the greatest mileage on a single charge of the battery. It is open to all types but will probably be contested by runabouts, with one or two possible entries of light delivery vehicles. The present record is said to be 244.7 miles, made on the streets of Cleveland, Ohio, in 1911. The road record is 176 miles made recently in a run from Boston to New York.

A second test provides for a continuous day and night run throughout the ten days of the Show. This is to be accomplished by having two batteries to be used alternately, or by giving one battery the required number of short "boosts." This test is for commercial vehicles, as the results achieved will be most profitable for this type. As yet there is no record for a test of this nature and the one established during the Show is certain to attract wide attention.

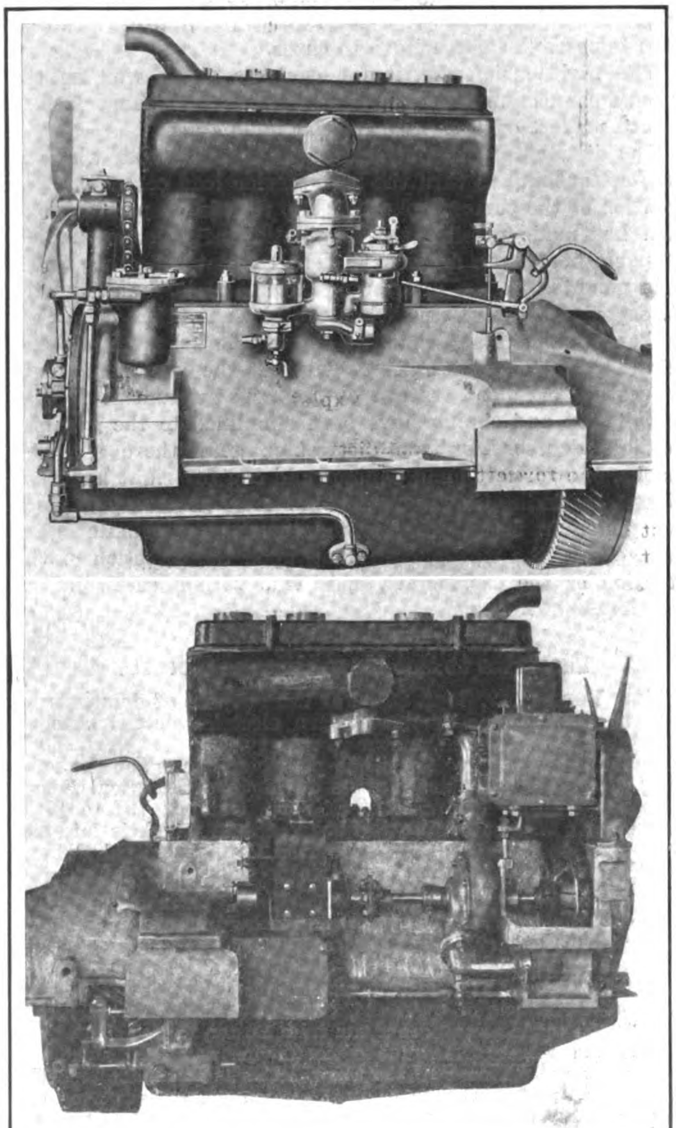
In addition, the New York Electric Vehicle Association is offering two handsome cups for road runs to be held during the Show, one for pleasure cars and one for motor trucks.

Stearns-Knight Four for $1,750

High-Speed Motor Has 3 3-4-Inch Bore and 5 5-8-Inch Stroke—Counterbalanced Crankshaft—Tubular Connecting-Rods—Gear-box Brake—Cantilever Springs



New four-cylinder Stearns-Knight five-passenger touring car which, with complete equipment, including electric starting and lighting, sells for $1,750



Upper—Intake side of new Stearns-Knight motor, showing integral intake manifold. Note automatic lubrication control interconnected with carbureter

Lower—Exhaust side of new Stearns motor, showing integral exhaust manifold and mounting of high-tension Bosch magneto and Gray & Davis system

A FOUR-CYLINDER, high-efficiency, high-speed Knight motor in a five-passenger touring car at $1,750 is a most important trade announcement in these days when the battle among six-cylinder, four-cylinder, and eight-cylinder is rapidly growing acute.

This is what the F. B. Stearns Co., Cleveland, O., is doing. The factory has already started production on 1,500 of these $1,750 cars for 1915. The first lot of 500 started through the factory in August, production is well under way today and demonstrators have already been shipped to dealers.

The new four-cylinder job with a motor 3 3-4 by 5 5-8, a wheelbase of 119 inches, 34 by 4-inch tires, weighing complete with all equipment 3,100 pounds, and having a rear axle gear ratio of 4 1-2 to 1, shows 45 miles per hour continuous speed on the brick roads around Cleveland, with a cabriolet body for two passengers. As a cabriolet, the price is $2,250, and as a limousine $2,850. All use the same wheelbase.

Many Features of European Design

To produce a Knight motor of the latest design for $1,750, as a five-passenger touring car, marks the début of a new era in Knight-motored vehicles in America. Heretofore they have sold much above this mark. But besides a lower price, the Stearns company incorporates in this new motor many other features found in the high-efficiency, high-speed, four-cylinder motor of Europe which are new in America. These include the counterbalanced crankshaft, counter weights being used to overcome bearing wear, caused by centrifugal force. The connecting-rods are hollow to give lighter weight, and on the lower ends are extensions for balancing purposes. An exceptionally light casting is used for the cylinder block, the wall thickness being only 5-32 inch. The aluminum crankcase is very rigid.

The new chassis introduces many other features new with Stearns such as integral intake and exhaust manifold, a single ignition system using a high-tension magneto, a service brake on the rear of the gearbox, cantilever rear springs, spiral bevels in the rear axle, pressed steel housing for the rear axle, gasoline tank in the cowl, and a reverse cone clutch.

A Real Factory-Made Car

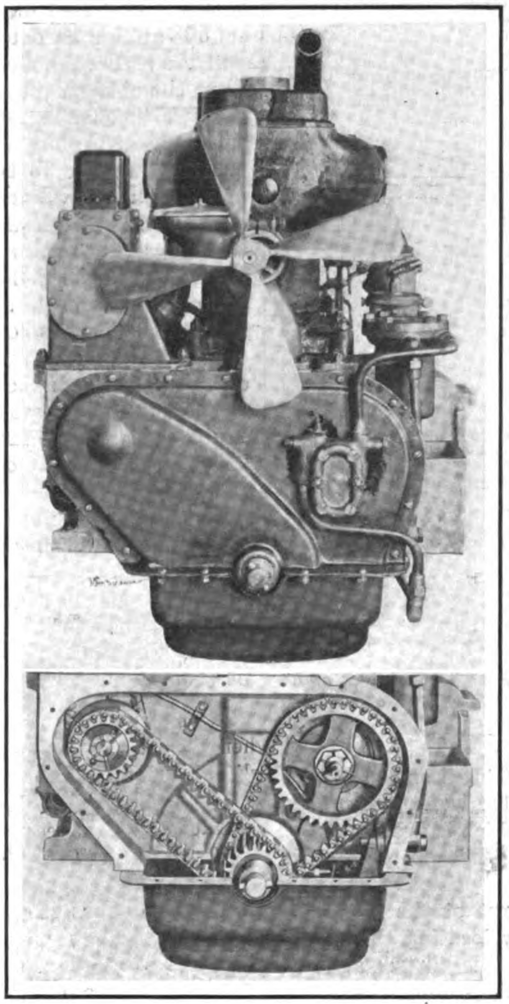
A remarkable aspect of this new Stearns Knight is the fact that it is a factory-made car in every sense of the word, and not an assembled car. The Stearns factory produces nearly all of the parts. For example, the motor is made entire in the plant with the exception of magneto, starting and lighting units and silent chains. The company manufactures the crankshaft, eccentric shaft, connecting-rods, pistons, and does all the work on the forgings and castings entering into the motor. The gears and shafts for the gearset are factory products. This category also includes rear axle, steering gear, front axle, etc. The Stearns company does not manufacture the forgings or castings entering into the car, but does all the work on the manufacture of these.

Many Stampings Used

Considerable use has been made of stampings because they are lighter in weight than forgings and castings which might be used in their place and they are cheaper to manufacture. Some of the stampings include, in addition to the base of the crankcase and the timing chain cover, brake drums, differential cover, rear axle and many smaller parts.

Rigid Crankcase

Considering the various chassis constructions and details, first comes the general design in which the motor, clutch and gearbox constitute a unit construction supported at four points on the frame, at the corners of the motor, and in which the heavy-section, aluminum casting forming the top of the crankcase also divides at the rear, leaving an opening for the flywheel and back of this carries the gearbox as a unit. This construction is one of the foundation stones in this motor design in that rigidity in the crankcase has been considered a necessity for efficiency in high-speed motor work in both foreign and American practice.



Upper—Front view of new Stearns-Knight four showing mounting of fan, carbureter and lighting generator. Lower—Interior view of timing gearcase on new Stearns-Knight

Light Weight an Aim

The block cylinder casting is a symmetrical design with its integral manifolds on opposite sides. The castings have uniform wall thickness throughout of 5-32-inch, which is in keeping with European practice. The base of the crankcase is a steel stamping and stampings are used as covers for the timing chains driving eccentric, magneto and pump shafts. This use of stampings is a part of the general engineering scheme of the car to reduce weight wherever possible and also to reduce construction cost.

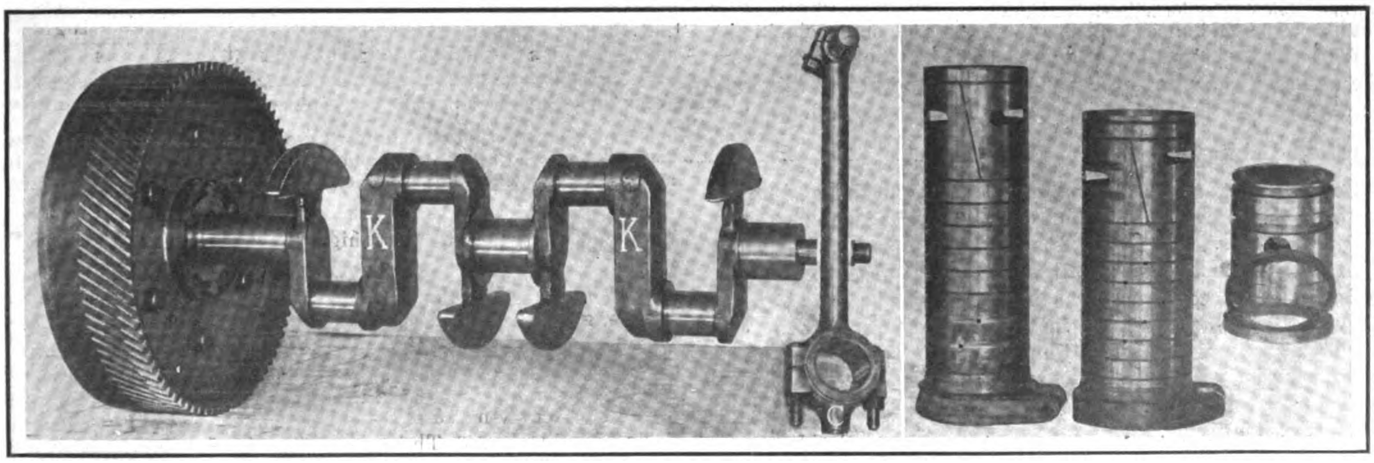
Counterbalanced Crankshaft

The most important feature of the counterbalanced crankshaft with its four integral crescent-shaped weights, is the two particularly heavy crank cheeks K used in order to give the required rigidity. All three of the main bearings are 2 1-2 inches in diameter and the lengths are, rear 4 1-2, center 2 3-4, front 2 3-8. The four crank pin bearings are 2 inches in diameter and are 2 3-8 inches long.

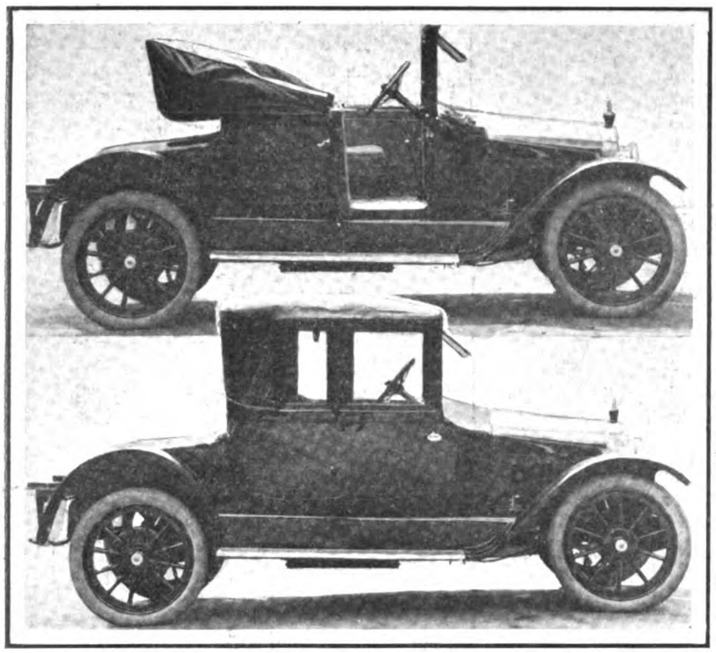
Stress Eliminated

The balance weights are used not to put the crankshafts in rotary or dynamic balance, for it is in rotary balance and also dynamic balance without these, but these are added to eliminate the stress on the bearings due to centrifugal force at speeds above 1,200 revolutions per minute. It has been found in high-speed motors that at continuous speeds above this point, the bearings wear, due to pressure not from the explosions and not from the actual weight of the crankshaft and other parts carried, but to irregular, centrifugal force on the shaft. This can be explained by the comparison of swinging a weight attached to a string around your finger. The faster you swing the weight the stronger is the tendency for it to fly away. With a single weight on a string the pull is always in the direction of the weight. If, however, we arranged two weights, one diametrically opposite the other, and then swung them in a circle, the centrifugal force of one would neutralize that of the other. This is what the counter-weights are used for. By neutralizing this centrifugal force inherent in the shafts without the weights, the wear on the bearings is eliminated.

Another factor is the tubular connecting-rod used for the



Left—Counterbalanced crankshaft used in new Stearns-Knight four-cylinder motor, showing the integral crescent-shaped weights, of which there are four. Two very heavy crank cheeks K are used for rigidity. Right—Cast iron pistons used in new Stearns-Knight four motor



Upper—New Stearns cabriolet with top folded. Lower—The same car with the top raised. This car sells for $2,250 and is mounted on the new Stearns-Knight four chassis

first time by Stearns. These rods are lighter than the I-beam type, an object desired in high-speed motor work, and on the connecting-rod cap is a short stub tube which is used to assist in getting better balance in the motor. The object of this extension is that the center of gravity of the entire connecting-rod mass at the lower end is brought at the center C, which is the center of the crankpin. By locating the center of gravity of this mass at the center of this pin vibration is eliminated which would be set up were the center of gravity at any other point than C. The hollow connecting-rods have a wall thickness 5-32 inch, and the hole is 5-8 inch.

Pistons are cast-iron ones with considerable length and slightly concave on top. The two rings are carried above the wristpin and the piston has considerable wearing surface between these rings which is used to prevent slapping and give a quieter motor. Each piston groove contains three rings, a broad inner one and two narrower ones outside of it.

As in all other Knight motor types, the two reciprocating sleeves are used, these being cast iron constructions with the usual annular grooves for lubrication and two sets of ports at the upper end of each sleeve, the ports on the one side for the exhaust and the opposite for the intake. These sleeves have a total reciprocation of 1 inch and are driven by short connecting-rods from an eccentric shaft. Morse non-adjustable chains drive this shaft and the magneto and pump shaft, the arrangement being triangular with a third short chain from the magneto shaft to the Gray & Davis generator. This may be seen in the illustration in the center of page 639.

Constant Lubrication

For the first time Stearns has eliminated the system of motor lubrication in which movable troughs are used, one under each connecting-rod. Instead is a non-splash system with varying pressure to all of the crankshaft, crankpin, wristpin, and eccentric shaft bearings, and a mist to the sleeves. The oil pressure is interconnected with the throttle, so that at normal speeds of 15 miles per hour the oil pressure is 20 pounds, yet when the throttle is open, there is an increase in pressure until 60 pounds is reached, at which point there is a safety valve which prevents a higher pressure. The prime object of this lies in the fact that a constant film of oil is desired in all of the bearings all the time.

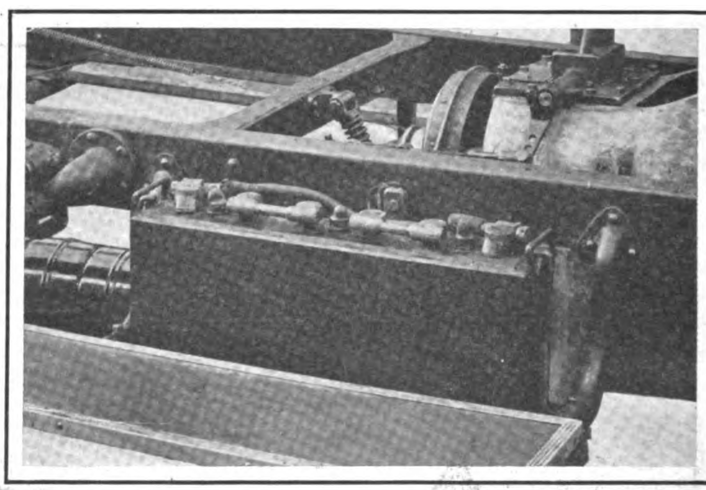
The oil system is conspicuous in that the parts are largely external: The gear pump is located externally at the front where it is driven direct from the eccentric shaft. It draws its oil through an external pipe from the crankcase base, and delivers it through another external pipe to a large cylindrical filter chamber on the left front of the motor. From this filter it flows through a 7-8-inch pipe incorporated in the crankcase and having branches to the three bearings of the crankshaft as well as to the forward end of the eccentric shaft and also to the water-pump shaft. The crankshaft is drilled so that oil is forced direct to the crankpins and lower ends of the connecting-rods, and thence through the hollow connecting-rods into the hollow wrist pin. The wristpin has brass end plates to prevent an excess flowing out against the sleeves and thus causing smoking.

Still another feature to prevent smoking due to too much oil rising through the connecting-rods and escaping through the wristpins, is that a small hole is drilled near the lower end of each connecting-rod.

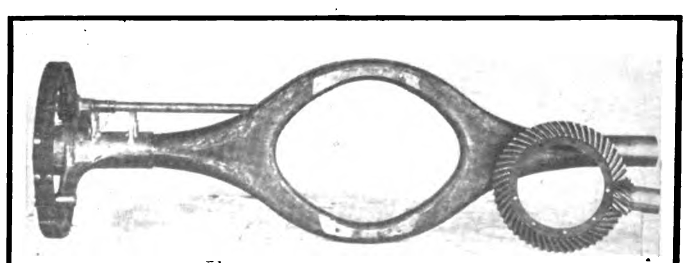
Three elements enter into the electrical system: First, the Bosch, single high-tension magneto gives an ignition system with one set of plugs and wiring reduced to the minimum. Starting and lighting are cared for by a Gray & Davis starting motor and a Gray & Davis generator. The starting motor, located under the right rear motor arm where its engaging pinion meshes with spiral teeth on the flywheel, is geared 30 to 1 to the crankshaft and is capable of spinning a cold motor 84 revolutions per minute.

The generator for the lighting system is mounted at the right front where it is driven by silent chain from the pump and magneto shaft. It has a ratio of 3 to 1 of the crankshaft and starts charging the battery at 12 miles per hour. The complete system is a 6-volt one with an 80 ampere-hour Willard battery in which the three cells are placed in line thereby giving a battery case that can be suspended on the right between the frame and the running board.

The clutch, incorporated in the flywheel, is a leather-faced one with springs operating under the facing. The reverse position of the cone, which moves backwards to engage in-



Neat disposition of the batteries on the Stearns-Knight new four. The three cells are placed in line, thereby permitting their suspension on the right between the frame and running board



Axle stamping used in new Stearns four for lightness and strength. The bevel gear and drive pinion are shown at the right stead of forward, has been done solely to simplify the disengaging connection.

Three forward speeds and one reverse are afforded in the gearset, which is compactly housed in the extension of the casting forming the crankcase. There are end plates for carrying the bearings. Double-roll, annular ball bearings are used for the main shaft and Hyatt's for the countershaft, reverse shaft, and where the forward end of the main shaft is supported within the pinion, from the shaft connecting with the clutch.

Power is conveyed from the gearbox through a propeller shaft having but a single universal joint which is at its forward end. Instead of conventional bevel gears in the rear axle, the spiral bevel is used, this giving a quieter drive.

The rear axle is a new design with Stearns in that the stationary portion is a diamond-shaped steel stamping of 7-32-inch stock, and having an opening into which the differential housing is secured. In external appearance the axle is not unlike the present steering axle, but is lighter, due to the stamping. The shafts can be withdrawn without dismantling the axle.

Brake Behind Gearbox

An innovation in the brake arrangements is placing the service brake on a drum immediately in the rear of the gearbox. This drum, measuring 10 1-2 by 2 inches, is so located as to be practically over the large rear bearing of the main shaft of the gearbox on which it is carried. The contracting bands faced with fiber are brought together by a wedged-shaped piece which is drawn forward by a horizontal rod passing through a tube in the gearbox and at its forward end couples direct with the pedal, giving a very direct pull. On this rod, at the rear of the wedge piece, is an adjusting nut, and to the rear attaches a spring which pulls it backward when the pedal is released. There is also a vertical spring which tends to separate the ends of the brake bands. The end of each brake band carries a small roller which bears on the inner face of each arm of the wedge.

Emergency Brakes on Rear Wheels

The emergency brakes are expanding malleable iron shoes which bear on pressed steel drums attached to the rear wheels. These drums are 7-32-inch stock and measures 15 by 1 1-2 inches.

The cantilever spring is new and the springs are shackled at their forward ends, have a pivoted bearing support on the frame at the center, and at the rear fit to a bolt beneath the axle. The leaves are 2 1-2 inches wide and the spring measures 50 inches in length. The pivoted central support is not exactly in the center but positioned 23 inches from the front end and 27 from the rear. The drive of the rear axle to the car is through the long leaf of the spring rather than through radius rods. A pressed steel torque member parallels the propeller shaft and has the usual front end support.

The steering system has been developed to meet the requirements of a car selling at medium price. The steering gear is manufactured by Stearns as are the other parts of the system. On the wheel are the spark and throttle levers above the wheel and a center control button which, when pressed, pounds the electric horn, and, when turned, controls the lights. An ignition cut-out is provided above the wheel. Within the steering column, instead of there being the usual concentric tubes, one to carry the spark control, another the throttle control, etc., there is a series of four rods. One of these rods carries the spark control, another the throttle, and a third the switch and horn.

Too Many Tire Sizes

ENGLAND is having more trouble in the present war with too many different diameters and sections of solid rubber tires for trucks than with the mechanical defects of these trucks. There are not fewer than 120 different tire sizes at present in use on the British trucks doing service in the war zone. Carrying an adequate supply of spare tires is in itself a herculean task, but there is still the other task of the manufacturer, in that he has not on hand for ready distribution enough of the different sizes to meet the requirements.

Necessity always has been and still will continue to be, the mother of invention, and war has always been a great stimulator of ideas, and a force to bring about in relatively short time movements that it frequently requires years to accomplish. The British car maker as well as the British tire maker has been slow in the work of standardization, both have lagged behind the work America has done in this regard. The present war has demonstrated how imperative it is to have standardized parts, not only in cars but in equipment.

Last summer the Society of Automobile Engineers took hold of the problem of reducing the number of pneumatic tire sizes in America. The original draft of the plan of operation contained about eight different sizes and about six different diameters for over-size tires, making a total of fourteen or fifteen. The makers have agreed that better results could be had with fifteen different tire sizes than with the forty-seven different sizes that they manufacture at present. Cutting from forty-seven to fifteen sizes would mean economy to the tire maker, but it would mean greater economy to the tire users, by way of possibly cheaper tires, greater stock of all sizes in the different depots and perhaps a better adjustment of the tire to the load or weight of car, than is now had.

But our S. A. E. can go further, and, cutting a leaf from the book of experience in the present war, start vigorously on the work of cutting down the number of sizes of solid tires. The lesson that Great Britain is experiencing is one that should be quickly seized upon, the sooner the better. Fewer sizes of solid tires will mean much to the truck owner, who may find difficulty in getting a ready supply of tires in all parts of the country.

The Latin-American Sale

SANE business is one of the greatest requirements of today, when makers have found the doors of Europe closed to their passenger car business and it becomes necessary to develop fields in Latin America or other lands not directly affected by the present hostilities.

This is no period to stampede business in new fields. It is impossible. Rather this is a most opportune moment to begin the missionary work in the twenty or more Latin-American countries. These countries offer excellent fields for business but you need something more than a Spanish catalogue and a moving picture film of your factory to secure that business.

It is hard to do business with a man when his banker has failed him. Just at this moment South America's bankers have gone back on it, because those bankers are European countries at present at war. With conditions in South America such that a three-months' moratorium was the first necessity on declaration of war, how can the American maker expect to pursue his old policy of getting money for his automobile as soon as it is loaded on the ship in New York harbor; and yet some makers, who are at the present moment trying to enter the thin edge of the wedge in Latin-American business are today boasting that South America will have to come to their terms and buy cars on this pre-pay basis.

It is foolish to play the ostrich rôle of sticking your head in the sand and imagining you are safe, because you cannot see the other party. This is almost a parallel of what some of our American countries are doing.

Instead of this we must meet Latin American countries at least on the same basis that European countries met them when they started developing their business. We must be prepared to give credits, and not short ones either, but some that will extend as long as nine months, perhaps twelve. Credit accommodations are needed today in every one of the twenty Latin-American countries. We have to aid in financing these lands before they can buy our merchandise.

Some automobile manufacturers have already announced that business cannot be done this way; that the automobile industry is different from all other industries; that although credit accommodations have been necessary in other mercantile lines yet such are impossible in the automobile industry. Perhaps with several companies it may be impossible at the present, but the situation remains, that we will have to meet Latin Americans more or less on their own methods of doing business.

Credits of sixty and ninety days have not been injurious to European trade in the past. The draft at this period covering the value of the goods, which the buyer in a Latin-American country must accept and endorse and which his banker holds until collection is due, has proved satisfactory in the past. Failure to meet such a draft is equivalent to action in bankruptcy. Europe has found this system satisfactory and America will, it is almost a certainty, have to meet the requirement of South American business in the same way.

The maker who wishes to entrench himself in South America should start now. He must start in a sane business-like manner, not with any whirlwind campaign, with cut prices and large press advertisements, but rather with a good stock of cars, with a better stock of parts, and with a force of mechanics who know the car, know how to drive it and how to take care of it. The salesman must establish confidence as the first requisite of business.

New York S. A. E. Discusses Tire Abuse

NEW YORK CITY, Sept. 24—Two interesting papers were presented at the S. A. E. meeting held at the Automobile Club of America tonight. This was the first Fall meeting of the Metropolitan Section. One of the subjects presented had to do with the causes and effects of tire abuse, illustrated with many lantern slides. It was presented by Mr. L. Greenwald, of the Firestone Tire & Rubber Co., Akron, O. The other paper dealt with tire fabrics and was given by H. Van R. Scheel, of the Brighton Mills.

In Mr. Greenwald's paper many points that affect tire economy were brought out. One slide showed the effect of applying the brakes too suddenly, causing the wheels to slide. The tread was roughened and torn so that its life was materially lessened. The same effect might be brought about by a clutch that did not engage smoothly or by careless use of the clutch in starting the car.

Several illustrations of worn and loosened treads caused by wheel irregularities were given. Wheels out of round, or out of alignment, loose demountable rims, bent axles or spindles, bent steering arms, etc., were mentioned as causes of the quick deterioration of the casings. The canting of the wheels was mentioned and it was stated that practice varied greatly in this particular. The maximum amount was 1 1-8 inches and the minimum 1-4. That is to say that the distance between the top and the bottom of the front wheels was this much greater at the top than at the bottom. With more than 1 1-8 inches the tendency was to tear the tread loose in a short time.

Another slide showed the tread of a racing tire that had been worn away in a short time due to the high speed alone. Such a tire can be made almost as good as new by retreading, because the fabric is still in good condition. The wearing away of a racing casing is due to both the tearing action that the tread is subjected to and also the heat which in many cases softens the rubber so that it loses its strength and melts away, so to speak.

Temperature in Touring 150 Degrees

The temperature in ordinary touring is not over 150 degrees Fahrenheit and sometimes not more than 130, while in racing it is not believed that the temperature goes above 200, unless the tires are underinflated. It is difficult to obtain relable data on this phase of the subject, because it is almost impossible to determine the temperature with accuracy.

Damage due to running in car tracks takes the form of cuts in the sides of the tread and there is a likelihood that the fabric is broken also. A small amount of driving in car tracks will not hurt the tires appreciably, but the continued practice of this will result in the trouble described. After the tread becomes cut, moisture and dirt enter and in time loosen the tread from the fabric. Meanwhile, any broken places in the tread are becoming worse, so that a premature blowout due either to rotted fabric or a weakened tread results.

Underinflation not only produces cracks in the sidewalls of the casing but it also has a tendency to loosen up the top of the tread by wave effects set up in it. Furthermore the beads of the tire are weakened by the extra strain.

Fifteen to 18 pounds per inch of tire section in the front and 15 to 20 pounds in the rear is the correct amount.

Reliners are advisable only when used in old shoes, and then only when properly manufactured and of good material.

Many examples of careless application of tires and tubes were given. One slide showed the effect of putting the flap of the tire next to the tread with the result that the tube was chafed and punctured. Another showed where a straight sided tire had been put on a clincher rim without filler rings, the result being that the walls of the shoe were broken. A similar example was one in which a clincher tire was placed on a wheel with reversible rings, but the mistake was made of only reversing one ring. The result was that the side walls gave out.

Too much lubricant was shown to be just as serious as too little. A lump of soapstone will cause chafing and heating and a puncture may result. On the other hand, too little lubricant causes the tube to stick to the casing and permanent stretching of the tube results. This effect is due to the fact that when the tube sticks to the casing the continual working of the latter takes the elasticity out of the former and it takes a permanent set. The set of the tube is due to the heat developed.

Graphite Good but Dirty

Flake graphite is undoubtedly the best lubricant, but it is objectionable because it is so dirty. For this reason mica or soapstone are generally used. The lubricant should be rubbed well into both shoe and tube.

Pinched tubes are caused by a portion of the tube becoming caught under the shoe or else the tube becomes doubled back on itself with the result that it chafes and blows out.

When it is found that the tires wear on the side walls due to ruts, they should be rebuilt before the fabric is injured, and if it happens that the wall on only one side is worn away additional life may be obtained by reversing the shoe.

Driving a tire flat causes chafing of the walls, strains the bead, and bends the tube double and cuts it. The amount of the injury depends in a large measure, however, on the care with which the driving is done.

Oil on garage floors softens the rubber and loosens the fabric.

Overloading is much the same as underinflation, it causes the breaking down of the side walls.

Loosening of the tread is generally due to the neglect of cuts. After a cut appears, moisture and sand enter and rot and wear away the fabric and the rubber until part or all of it is loosened. The remedy is simply to repair the cuts as they appear.

Following this the paper on tire fabrics was presented. Mr. Scheel of the Brighton Mills stated that Sea Island cotton was superior to all other materials for tires because it has greater flexing qualities, stands heat better and is believed to be somewhat self-lubricating, due to the slight amount of oil secreted in the fibres. He showed how the present fabrics were evolved and brought to their present state of excellence. In the beginning the fabrics were light and cut parallel to the threads, but experience showed that heavier material was required. It was also found that when the fabric is cut on the bias so that the threads make an angle of 45 degrees with the rim greater strength and wearing qualities were secured for the reason that the stresses are distributed more evenly over all the threads.

U. S. Appoints Seven Commercial Attaches

These Will Go To Foreign Countries To Open Markets for American Manufacturers

WASHINGTON, D. C., Sept. 26—Motor car manufacturers who are making a play for foreign trade will be interested to learn that the Department of Commerce has recently appointed seven commercial attachés, who will be sent to European, South American and Asiatic cities to carry out plans of the bureau of foreign and domestic commerce for aiding American manufacturers to broaden their foreign markets.

The appointments are: C. W. A. Veditz, Philadelphia, to Paris; Prof. Lincoln Hutchison, University of California, to Rio de Janeiro; Irvin W. Thompson, North Carolina, to Berlin; Dr. Albert Hale, Indiana, to Buenos Aires; A. H. Baldwin, former chief bureau of foreign and domestic commerce, Washington, to London; A. I. Harrington, Ohio, to Lima, Peru; Julian H. Arnold, consul general at Hongkong, to act for China.

No time for the departure of the new appointees to their posts has been made, owing to the troubled situation abroad. The early departure of the South American attachés is planned, but the opening of the offices in London, Paris and Berlin will be delayed for a time.

S. A. E. Annual Meeting at Show Time

NEW YORK CITY, Sept. 30—The 1915 annual meeting of the Society of Automobile Engineers will be held in this city early in January during the time of the automobile show.

The divisions of the Standards Committee are now resuming active work. The next convention of the Standards Committee will be held during November, the sessions of the meeting probably extending over 3 days, upon which reports of divisions will be submitted and considered.

The Ball and Roller Bearings Division still has under consideration the matter of recommending a list of stock of sizes of roller bearings, eliminating many of the sizes now listed by manufacturers.

The Carbureter Fittings Division is making a close study with a view to determining whether it is feasible or advisable to recommend standards in addition to the present S. A. E. standard carbureter flange dimensions, to cover the application of side-outlet carbureters. The problem in question is radically different from anything the Carbureter Fittings Division has so far attempted in the way of standardization.

In response to the very few complaints that have been received, the makers of wood wheels for trucks have been asked to present their views on the thickness of S. A. E. felloe bands, and will probably attend the meeting at which the subject will be taken up by the Commercial Car Wheels Division.

The Iron and Steel Division has under consideration, modification and extension of steel castings specifications.

A report from the Lock Washers Division is expected on the question of whether the smaller sizes of the S. A. E. standard light series are too light.

The Miscellaneous Division will endeavor to establish a standard of speedometer drive-shaft ends at an early date. It has also been furnished by the authorities of practically all of the States of the Union with data as to the elements of license pads that govern the size and location of attaching devices.

It is expected the Clincher Automobile Tire Manufacturers' Association will at an early date act upon the matter of establishing a new rim size for the 36 by 5-inch tire.

W. A. Frederick, as chairman; W. R. Strickland and W. F. Herst were appointed a sub-committee to consider bell housings standardization. It is the view of the Standards Exchange Division, after investigation that five sizes of bell housings can probably be concentrated upon.

A sub-committee to take up with the Automobile Engine Manufacturers' Association the matter of arriving at accepted practice as to motor supports was appointed as follows: A. F. Knoblock, chairman; C. B. Rose and W. A. Frederick. The above-mentioned sub-committees are charged with consideration of fly-wheel diameters, tailshaft details, etc., and all other matters connected with the interchangeability of units where engines and transmissions are involved.

The Seamless Tubes Division has been discontinued, Chairman H. W. Alden having recommended that this be done.

The schedule of meetings of the Metropolitan Section is based on the work of its Research Committees, six of which have been appointed to investigate various subjects. The proposed program is as follows:

October 29—Report of Research Committee on Electric Transmissions, David Beecroft, chairman.

November 24—Report of Research Committee on Engine Characteristics, Robert McA. Lloyd, chairman.

Supplementary subject: Eight-cylinder Motors.

(Date advanced to Tuesday on account of holiday.)

December 29—Report of Research Committee on Engine Governors, A. J. Slade, chairman.

Supplementary subject: Magneto versus Dynamo Ignition.

January 28—Report of Research Committee on Greases, H. M. Martin, chairman.

Supplementary subject: Asphalt vs. Paraffin-Base Lubricants.

February 25—Report of Research Committee on Kerosene Carbureters, A. B. Browne, chairman.

Report of Research Committee on Non-Electric Continuous-Torque Transmissions, L. M. Dieterich, chairman.

Lozier Reorganization Is Probable

DETROIT, MICH., Sept. 30—*Special Telegram*—While the inventory started by the Detroit Trust Co., temporary receiver for the Lozier Motor Co., is not completed, conditions to date are satisfactory and will more than likely lead to reorganization shortly. At a directors' meeting, President Joseph M. Gilbert was authorized and directed to file an answer in the U. S. Court stating that the company was not insolvent 4 months prior to the filing of the petition by certain claimants who had claimed insolvency 6 months prior to filing of their petition.

DETROIT, MICH., Sept. 25—Judge Tuttle of the United States District Court, has named the Detroit Trust Co. temporary receiver for the property of the Lozier Motor Co., and officials of the trust company are now busy both in Detroit and in Plattsburg, N. Y., making an inventory of the company's property.

In the court Judge Tuttle suggested to all interested that an effort be made for a reorganization of this old and so well known automobile company, and it appears from what attorneys and creditors say that the effort at re-establishing the Lozier Co. upon a sound basis may succeed.

What South America Needs Most

WASHINGTON, D. C., Sept. 29—"**What is needed at this hour in Latin America is not so much a supply of the manufactured products of the United States, although required in considerable quantities, but money, loans and advances, credits on purchases, and markets at reasonable rates for raw products which usually go to Europe.**"

This sums up the South American situation as interpreted by the Pan-American Union which recently obtained cable reports from thirty-four different cities in South America and Central America on business conditions in twenty of these Latin-American countries.

Champion and Jeffery-Dewitt Consolidate

TOLEDO, O., Sept. 25—The Champion Spark Plug Co., the largest manufacturer of spark plugs in the world, and the Jeffery-Dewitt Co., Detroit, one of the oldest spark plug manufacturing companies in the country, have consolidated and the business of the companies will be conducted from Toledo, from where the J-D and Reliance spark plugs, which have been made by the Detroit concern, will hereafter be marketed in addition to the Champion plugs.

The Jeffery-Dewitt Co. will be devoted from now on exclusively to the manufacture of porcelain and porcelain products.

Recently the Champion plant has been greatly enlarged through the addition of 40,000 square feet of floor space and the spark plug machinery and equipment of the Jeffery-Dewitt company will all be moved to this city. At present the Champion company has a daily output of 25,000 spark plugs, but this will be increased, probably by 5,000 to 10,000.

The Jeffery-Dewitt company, which has a capacity of more than 35,000,000 pieces of porcelain per year, is said to make better porcelain than the imported.

The Jeffery company was organized in 1907, having started in business in Newark, N. J., and employed at that time twenty-five to thirty men. At present its force is about 400 men.

NEW YORK CITY, Sept. 29—A. B. Cordner, W. A. Allen and David Wills have formed the Motor Devices Co., to handle automobile accessories. They have incorporated for $30,000.

Ford Adds Coupelet—Sedan—Chassis, $410

Better Finish and Novelties in Design in New Body Models—Gills Make Hoods More Attractive

DETROIT, MICH., Sept. 29—This year the Ford company is going after the closed car business more strenuously than ever by offering a coupelet and sedan on the regular model T chassis. These are the best finished bodies the Ford company has ever put out and the prices are $750 for the coupelet and $975 for the sedan. The other closed car model, the town car, is continued at $690.

The appearance of these new Fords is very attractive and besides the new bodies, the hoods have been provided with gills which add a distinctive touch. This gill feature is not applied to the regular open models, which remain the same as they have been, for the time being at least.

The coupelet is of the regular convertible type which has become so popular. The top may be folded back to make substantially an open runabout of the car, while when the top is raised and the door windows in place, it is a completely closed-in affair similar to a coupé. The top is of genuine leather and the lines of the body such that it should make a strong appeal. The seat is broad and wide and has deep upholstery, while doors are roomy with the glass in a sliding sash and slipping down into the panel, protected by waterproof flapper. Triple hinges are fitted to the doors to assure alignment.

The windshield is of special design, being double ventilating, the top section swinging outward or inward, while the bottom section swings only outward. When closed both sections are rigid. The entrance to the rear of the body is by hinged tailboard, lifting from the bottom, providing room for a suitcase, inflated tire or other articles. The cowl connects the hood to the dash in graceful line.

The sedan makes a nice town car, and provides seating for five. The rear seat has room for three, while there are two individual seats in front. The right hand front seat is on a pivot and folds back out of the way when not in use. Upholstery is of cloth.

There are two wide doors which open to the front, have triple hinges as in the coupelet, while an attractive windshield is also fitted. This has three sections, two at the top and one at the bottom, the driver getting plenty of air in bad weather while still protected. As in the coupelet also, the cowl slopes to the hood. Curtains of roll type are fitted to the windows, and the glass in the doors may be dropped by means of straps. The glass has no sash or woodwork around it.

Deliveries on the coupelet will commence about October 1 and on the sedan about November 15.

The Ford company has also announced that it will henceforth furnish chassis without body for $410. These may be used either by fitting delivery or other commercial bodies or special bodies. Heretofore when a customer wished only a chassis, the dealer has been obliged to purchase either a runabout or a touring car and remove the stock body. This he has then been obliged to carry in stock until he found a call for it. The new arrangement should therefore be of special advantage to the dealer as well as to the buyer who wants to fit a special passenger body or use the car for commercial work.

Many Makers Buy Bales of Cotton

NEW YORK CITY, Sept. 30—A movement has been set on foot, with the object of benefiting the cotton industry of the South, for all who can do so to buy a bale of cotton and hold it till the South recovers somewhat from the war depression. A number of our largest automobile manufacturers have taken part in this movement, buying large quantities of cotton themselves and instructing their agents to buy as well.

It is doubtful whether this movement will really be of benefit to the cotton industry, according to prominent bankers and cotton men of New York City, who define it as poor business and poor economics, and ask why we should not start similar movements to benefit the other industries of the country which are suffering depression due to the European war. These men also state that there is danger that people buying cotton at the present price will lose money on it.

Among the prominent automobile, accessory and supply manufacturers who are taking part in the movement are: Goodyear Tire & Rubber Co., Akron, O., Hudson Motor Car Co., Hupp Motor Car Co., Saxon Motor Car Co., Studebaker Corp., Detroit, Mich., Willys-Overland Co., Toledo, O., Partin Mfg. Co., Chicago, and Valentine & Co., New York City.

Motor Print Absorbs Motor Life

NEW YORK CITY, Sept. 28—The Motor Print Co., Philadelphia, Pa., publisher of *Motor Print*, the well-known monthly motorists' paper, has purchased *Motor Life*, another popular monthly motoring paper published by J. A. Wittmann, New York. *Motor Life* will be merged into *Motor Print* under the name of *Motor Print*. *Motor Life* subscribers will, beginning with the November issue, receive *Motor Print* which will incorporate some of the departments of *Motor Life*.

The great similarity in the nature of the two magazines makes it possible to merge these two strong motor monthlies. The clientèle of both is found with the motor car user and the consumer in general. Their circulation is national, and broadly distributed from ocean to ocean.

The Philadelphia publication office of *Motor Print* at 418-420 Sansom street, will continue to be the publication office of *Motor Print* after *Motor Life* has been merged with it.

COLUMBUS, O., Sept. 25—According to the announcement of the Ohio Agricultural Commission, automobile displays will play an important part in the first mid-Winter fair to be held at the Fair Grounds, Columbus, January 9 to 15.

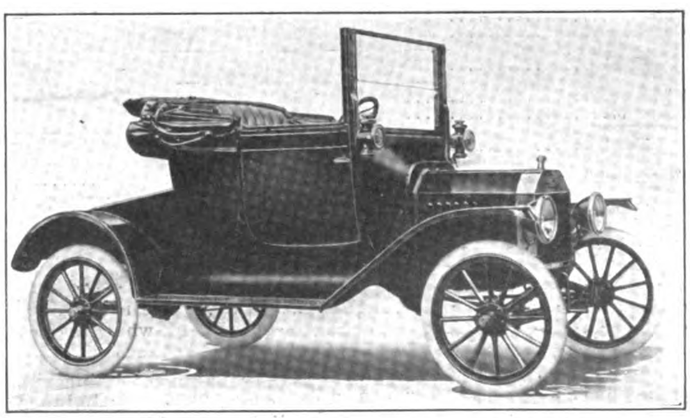
Denby Co. Announces New 1-Ton Truck

DETROIT, MICH., Sept. 24—In addition to its ¾-ton truck recently announced by the Denby Motor Truck Co., this company will also place on the market a 1-ton truck, identical in construction to the smaller one, the only difference being heavier springs and larger tires. The price will be $1,600, or $100 more than the 1,500-pound truck.

DETROIT, MICH., Sept. 29—C. T. Chenovert and Beckwith Havens, export and assistant export managers of the Denby Motor Truck Co., start today on a 2-years' demonstration trip around the world in a 1,500-pound Denby truck specially fitted for outdoor camping. From here the route leads to Vancouver via Chicago, Davenport, Omaha, Kansas City, Denver, Salt Lake City, Stockton, Los Angeles and the coast. From Vancouver the truck will be shipped to Honolulu, thence to New Zealand, Australia, Dutch East India, Asia, Japan. All of these countries will be given extensive demonstrations. Before starting for Europe all the South American countries will be visited.

New Sale for Wisconsin Engine Co.

MILWAUKEE, WIS., Sept. 28—On petition of the Bosch Magneto Co. and the Titusville Forge Co., Judge F. A. Geiger of the Federal Court at Milwaukee has ordered the sale of the property of the bankrupt Wisconsin Engine Co., Corliss, Wis., to be set aside and a new proceeding of sale held. Judge Geiger declares the former proceeding intolerable and says E. O. Nye, referee in bankruptcy, is guilty of gross irregularities. The plant brought $120,000 at the former sale and the referee's fee was $1,200. The petition of Bosch and Titusville stated that the sale was held without due notification of all creditors, including themselves.



New Ford Couplet selling for $750. Note louvres in hood

British Exports $17,204,-475 in 8 Months of 1914

LONDON, ENG., Sept. 15—During the first 8 months of 1914 ending August 31, the total value of the British automobiles, chassis, parts, motorcycles and parts thereof exported to foreign countries was $17,204,475, while the total value of the imported cars, motorcycles, parts and accessories totaled $27,474,700 or $10,270,225 more than what the British manufacturers exported.

As a comparison with the United States export and import business the total for the first 8 months of this year are not available, but those for 7 months show that during that period the American motor car and parts manufacturers exported such goods to the value of $20,729,440 and imported only $781,460. Judging from the way exports have been increasing it is fair to estimate that during the eighth month of this year the value of the exports totaled fully $2,500,000 which would bring the total export trade of the American makers during 1914 up to August 31, to $23,229,440 or $6,-000,000 more than the British manufacturers' business.

Overland Net Earnings, $5,864,858

NEW YORK CITY, Sept. 29—The Willys-Overland Co., Toledo, O., has issued its report for the year ended June 30, last. The income account follows: Net earnings, $5,864,858; reserve for contingencies, $300,000; interest on floating debt, etc., $333,583; total deductions, $633,584; balance net income, $5,231,274; preferred dividend, 7 per cent., $350,000; balance for common, $4,881,274; common dividends, 11 per cent., $2,200,000; balance, $2,681,274; provision for retirement for preferred stock, $250,000; surplus, $2,431,274; previous surplus, $3,070,959; total surplus, $5,502,233.

The balance sheet, as of June 30 last, follows:

Assets—Property investment, $22,291,784; investments in and advances to affiliated companies, $2,156,029; materials and supplies, $7,116,433; balance due from European distributing agent, $656,199; accounts receivable, less reserve, $2,929,660; notes receivable, $1,301,771; miscellaneous investment, $53,525; cash, $2,112,-760; deferred charges, $119,679; total assets, $38,737,840.

Liabilities—Preferred stock, $5,000,000; common stock, $20,000,-000; capital stock, sub-companies, $12,825; real estate mortgages assumed, $131,500; bills payable, $3,900,856; accounts payable, $1,-727,202; payroll and salaries accrued, $174,570; customers' deposits, $287,111; taxes and interest accrued, $102,260; reserve for quantity and other rebates to customers, $682,005; reserve for car repairs under guarantee, $30,000; preferred stock dividends due, $87,500; reserve fund, $1,099,778; profit and loss surplus, $5,202,-233; total liabilities, $38,737,840.

The balance available for the common stock is equal to 24.40 per cent. on the $20,000,000 outstanding.

S. G. V. in Reorganization Receivership

READING, PA., Sept. 28—With a view to reorganizing, certain officials of the S. G. V. Co., Reading, Pa., a Pennsylvania corporation, applied for a receivership last week. R. E. Graham, president of the S. G. V. Co., and vice-president of the S. G. V. Co. of Delaware, a holding company, was named. A creditors' meeting will be held today, after which, it is anticipated, that the factory, which has been temporarily shut down, will resume operations and work will be begun on the plan of reorganization. The receivership proceedings are intended to dispose of the holding company, which has a liability charge against the held company. Assets are said to be about double the liabilities.

Chandler Declares Extra 10 Per Cent. Dividend

CLEVELAND, O., Sept. 28—*Special Telegram*—A special dividend of 10 per cent. on the common stock of the Chandler Motor Car Co., the second dividend paid on the common stock within 90 days, was declared at the regular meeting of the board of directors today. In addition to the common stock dividend the regular quarterly preferred stock dividend of 1.75 per cent. was declared. After the payment of these dividends the company still had a surplus equal to the amount of its original cash capital.

Although the company has been manufacturing cars for less than 2 years the report of the treasurer of September 1 indicated a remarkably successful business. The sales manager's report showed a let up in business early in August at the beginning of the foreign war, but since that time sales have shown a healthy increase and the factory is now running on full production, with reports from all sections of prospects for a large Fall business. Even the South, which 30 days ago was affected by the cotton situation, is showing increased orders and the business from the grain-producing sections and the Pacific Coast is breaking all records.

Automobile Committee for N. Y. Tercentenary

NEW YORK CITY, Sept. 26—It has been decided by the Automobile Committee in charge of the Commercial Tercentenary automobile pageant on the night of Wednesday, October 28, to hold a contest for King and Queen of the pageant. This is to be decided by vote and is to be done in an unique way. The plan adopted for the coming contest is to allow each registered owner of an automobile in New York State one vote for King and Queen. Governor Glynn's acceptance of the Committee's invitation to ride at the head of the automobile pageant and review it from the Court of Honor, was welcomed by the Committee and other high officials will be invited to ride with the Governor.

The Automobile Committee has been made up and is composed of a number of sub-committees, totaling more than fifty members altogether. Elmer Thompson is chairman; George H. Duck, vice-chairman; M. L. Downs, secretary, and William C. Poertner, chief marshall. The chairmen of the sub-committees form the Executive Committee and include the following: Automobile Manufacturers Committee, Alfred Reeves; New York Automobile Dealers and Garages, M. J. Budlong; Brooklyn Automobile Dealers and Garages, Herbert L. Carpenter; Automobile Dealers and Clubs, A. G. Batchelder; Tires and Accessories, William M. Sweet; Importers, Emanuel Lascaris; City, State and Inter-State Departments, Commissioner William J. Lee; Transportation, Light and Power, R. W. Meade; Hotels and Amusements, H. M. Swetland; Clubs, Societies and Lodges, G. Murray Hulbert; Motorcycles, F. M. Baker; Automobile Daily Press, John C. Wetmore; Automobile Trade Press, Julian C. Chase.

N. Y. Dealers Fight Separator Repeal Veto

NEW YORK CITY, Sept. 28—The dealers and garagemen of New York City are preparing for the final move in their fight against the gasoline separator ordinance. They will attempt to have it repealed over the veto of Mayor John Purroy Mitchel.

The Board of Aldermen by a vote of 57 to 1 repealed the law which compels the installation of separators in garages, but the Mayor vetoed the repeal, explaining his act in a lengthly message.

The garage interests will appear this week before the general welfare committee of the Board of Aldermen and will offer evidence in refutation of the statements made in the message. Following this hearing the committee will report its recommendations to the Aldermen and the board will vote again on the measure. A three-quarters vote is necessary to pass the repeal over the Mayor's veto, but the garagemen have hopes of success. The vote will be taken October 6.

The main contention of the garagemen, that the separators do not operate at all successfully, was not touched upon in the Mayor's message, and this will be brought out with renewed emphasis in the present proceedings. Following the veto, the garage interests of the city held a consultation after which President R. H. Johnston of the Automobile Dealers' Association issued a statement which summarizes the testimony which will be given before this week's committee hearing. It follows:

The old officers of the New York Garage Association were retained at the annual meeting of the association held Thursday, September 24, at the Hofbrau Haus, New York City, and the gasolene separator question and the prospective raising of storage prices were discussed.

The garagemen have entered anew into the trade's fight against the separator, and will continue in an effort to have the repeal of the obnoxious ordinance passed over the veto of Mayor John Purroy Mitchell.

The proposed storage change consists in raising storage $5 a month and putting gasolene on a 5-cent profit basis. Heretofore storage has shown little or no profit, the profit of the garage business being derived from gasolene. But filling stations with their low prices have made a profitable storage almost imperative, and Thursday, October 1, it is planned that rates on the West Side, at least, be increased.

Rates are in two grades—A and B. A rates apply to the more modern buildings and will be $30 and $35; B rates will be $35 and $40.

The officers are: President, Louis J. Joscelyn, Joscelyn Garage; vice-president, William Burrows, Niagara Garage; secretary, Charles H. Potter, Uptown Garage; treasurer, William M. Haradon, Royal Garage. Directors: Bronx—W. L. Byrnes, Byrnes Garage; C. A. Otten, Bronx Garage. Washington Heights—H. L. Hulse, Hulse Garage; S. W. Childs, (new) Childs Garage. Upper West Side—William M. Haradon, Royal Garage; J. Bierman, Manchester Garage. Lower West Side—Ben Blumenthal, (new) West End Auto Palace; Morris Segall, Apthorp Garage; James S. McIntosh, McIntosh Garage. East Side—William Burrows, Niagara Garage; Joseph Stafford, Duford Garage. Downtown—Louis J. Joscelyn, Joscelyn Garage; Frank S. Hannah (new), 49th Street Garage. Harlem—Charles H. Potter, Uptown Garage; Charles Strathman, Strathman Automobile Co.

—

SAN FRANCISCO, Sept. 25—The latest figures given out by the California motor vehicle department are 114,657 licenses issued to automobiles up to September 20.

—

DETROIT, MICH., Sept. 25—The Bower Roller Bearing Co., this city, has declared its semi-annual dividend of 5 per cent.

—

BATAVIA, N. Y., Sept. 25—The Batavia Rubber Co. has declared a quarterly dividend of 1 1-2 per cent. on the preferred stock and a quarterly dividend of 1 per cent. on the common stock and an extra dividend of three-fourths of 1 per cent. on the common, payable October 1.

—

Standard Oil Case Before Grand Jury

JERSEY CITY, Sept. 25—Assistant Prosecutor G. T. Vickers of Hudson County today declared that the complaint against the Standard Oil Co. by the Crew-Levick Oil Co., which was dismissed by Judge Mark A. Sullivan on September 21, would be submitted to the grand jury.

In a statement today he said: "The complaint against the Standard Oil Co. for having violated one of the so-called 'Seven Sisters' acts will be submitted to the present grand jury at the earliest possible date, giving that body the benefit of all the testimony available to the state."

—

Government May Buy Trucks Next Spring

WASHINGTON, D. C., Sept. 26—It is likely the government will be in the market early next year for a big fleet of motor trucks. Postmaster-General Burleson is conferring with a special committee of postmasters and post office department officials looking to the substitution of government-owned motor trucks for screen mail wagons.

Contracts for screen wagon delivery in thirty leading cities expire next June and will not be renewed if the department decides that motor trucks are more economical and efficient.

—

N. Y. City Wins Taxicab Stand Fight

NEW YORK CITY, Sept. 29—The fight of the large taxicab operating corporations and the more pretentious hotels against the establishment of taxicab stands in front of the hotels by the New York City authorities has ended in favor of the city. Ornamental signs this week are being placed in front of all hotels and at all points where the city desires cabs stands. Each sign states the number of motor and horse cabs that may occupy the stand.

—

Ohio Tail Lights to Be Green?

CLEVELAND, O., Sept. 28—At a meeting of the legislative committee of the Ohio State Automobile Assn. held in this city it was decided to introduce bills at the next session of the legislature for the following purposes: Requiring all vehicles to carry lights at night, requiring tail lights to be green instead of red, reducing the dealers' license to $10, and requiring the elimination of headlight glare on country roads as well as on city streets.

—

BOSTON, MASS., Sept. 29—Gray and Davis, Inc., have declared their regular quarterly dividend of 1 3-4 per cent. on the preferred stock, payable October 1, 1914, to all stockholders of record at the close of business September 22. President William Gray reports that the factory is operating day and night.

Market Reports for the Week

This week's markets showed a downward tendency in prices. A weaker tone prevailed this week in most of the quotations. Most of the metal markets showed a decline. None of the prices showed a gain. In the rubber market further importations from Brazil are reported. The market retained a very steady tone. Only one change occurred in the oils and lubricants markets, and that was a decline of $0.02 for linseed oil. The rest of the markets were generally steady. The shipments of some of these products have been successful. The Norwegian bark Grande, has been engaged to take 6,000 barrels of refined petroleum, from New York to Copenhagen.

116 Franklin Sixes Average 11 M. P. H. on Low Gear

Dealers All Over Country Drive Under All Conditions for 8 Hours and 54 Minutes

SYRACUSE, N. Y., Sept. 26—One hundred and sixteen six-cylinder Franklin cars, driven by dealers in as many different cities, ran all day long on low gear Thursday, September 24. These 116 cars covered about 100 miles each in the average time of 8 hours 54 minutes, which is at the average speed of approximately 11 miles an hour. The average consumption of gasoline was 12.01 gallons and of oil about 1.17 gallons. James Sweeten, Philadelphia dealer, completed the 100 miles in 6:55, which averages 14.4 miles per hour and is the fastest time made.

Of the 116 cars to start, but one failed to finish. The Pittsburgh, Pa., dealer was forced to stop after covering 95 miles because of magneto trouble.

The tests were made under widely differing conditions. The highest temperature encountered was in Redlands, Cal., and in Concord, N. H., where the thermometer registered 92 degrees Fahrenheit. The lowest temperature was in Fort Dodge, Ia., where the mercury stood at 52 degrees.

In holding this national demonstration, which follows the national fuel economy demonstration which was run off May 1, and in which 94 Franklin cars averaged 32.8 miles to the gallon of fuel, the Franklin Automobile Co., Syracuse, N. Y., had in mind not so much a plan to make plain that the Franklin system of direct cooling by air will cool, for that fact already is well established.

That there might be no doubt of the authenticity of the test, it was officially observed and the records sworn to before a notary public at the conclusion of the run. Each car carried, in addition to the driver, two observers who in a great many cases were high civic officials and in others were newspaper men.

The routes which were chosen for the test included some of the hardest which could be found in the territories of the various dealers, and the runs were made regardless of weather and road conditions. Thus, for instance, the Bar Harbor, Me., dealer was obliged to make four detours through rough pasture land; The Wilkes-Barre, Pa., dealer finished at the top of the famous Giant's Despair Mountain; the Denver, Col., dealer climbed to the top of Berthoud Pass and finished on Lookout Mountain at an elevation of 11,500 feet; the Greensburg, Pa., dealer drove continually in rain; the Carthage, N. Y., dealer also drove in pouring rain and by way of adding a feature finished with a little girl standing barefoot on top of the engine bonnet; the Pittsfield, Mass., dealer finished at the top of the Jacob's Ladder; the Los Angeles, Cal., dealer negotiated what is considered to be the hardest climb in the State and finished at the top of Wilson's Peak at an altitude of 5,800 feet.

The cars that were used for the test were stock demonstrators, and in making the 100-mile run on low gear their engines turned over the equivalent of 336 miles on high gear.

Kansas City Dealers Hold 6-Day Tour

KANSAS CITY, MO., Sept. 25—Fourteen motor cars—all stock models of the 1915 lines—proved their worth in the second annual trade winning tour of the Kansas City Motor Car Dealers in a 6-day run through Kansas last week. The cars left Kansas City in the mud of a 5-inch rain that had fallen in a cloud-burst the night before.

One day of the trip was given over to the Kansas state fair at Hutchinson, at which the cars were parked and demonstarted. The cars that made the trip were the Chevrolet, Paige, Mitchell, Case, Paterson, Jackson, Allen, Krit, Pathfinder, Oldsmobile, Briscoe, Buick, Chandler, Car Nation and Saxon. The route took in Ottawa, Emporia, Newton, Hutchinson, McPherson, Salina, Manhattan, Topeka and Lawrence. Stops were made at each place and the cars demonstrated to local prospects and dealers.

Denver Show and Races Make Big Hit

DENVER, COLO., Sept. 26—Thirty-one cars were exhibited in Denver's first fall automobile show yesterday and today, and the event was so well attended that some of the dealers are already urging that it be made an annual affair. The show and 2-day race meet combined were attended by nearly 10,000 people.

The makes shown were the Empire, Hudson, Pathfinder,

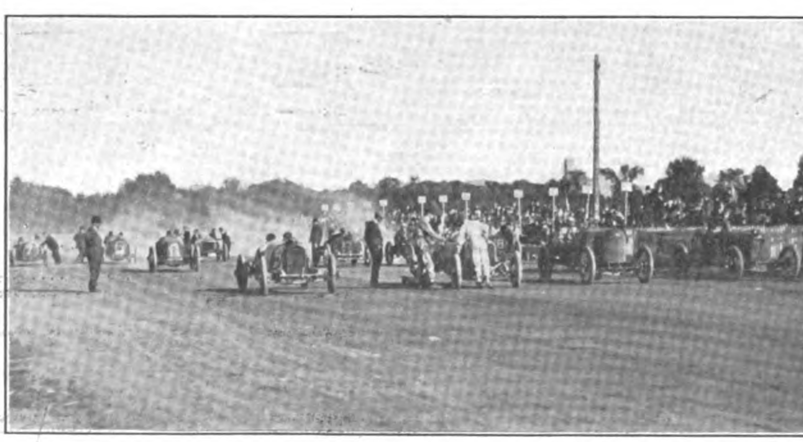
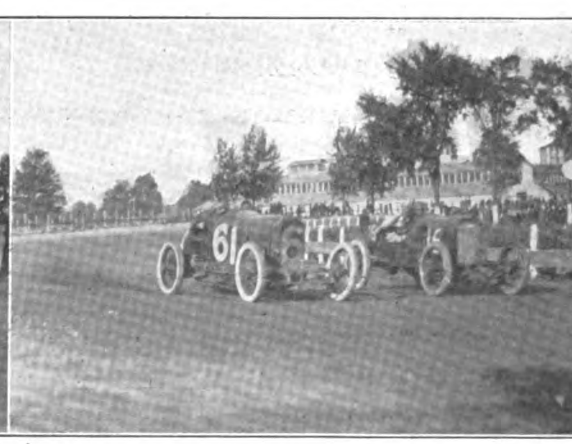
Results of Franklin low gear test





Left—Cars lined up before the start in Kalamazoo, Mich., 100-mile race. Right—Burman and Newhouse fighting it out on a turn

Studebaker, Regal, Briscoe, Winton, Jeffery, Buick, Abbott-Detroit, Chalmers, Detroiter, Crescent, Chevrolet, Maxwell, Overland, Moon, Hupmobile, Ford, Franklin, Reo, Oldsmobile, and the Fritchle, Baker and Rauch-Lang Electrics.

There were hundreds of visitors from outside of Denver and many prospective sales developed. The dealers are highly pleased with the outlook for the 1915 business and believe the show and race meet will prove a substantial trade stimulant.

The results of the races were as follows:

Five-mile, Gaston Morris, Buick, first; time, 5:21; Bob Murray, Buick, second, 5:30; E. W. Swanbrough, Mercer, third, 5:38 1-2. Fifteen-mile, Harold Brinker, White, first, 15:15 1-5; Bob Murray, Buick, second, 16:04 4-5; Gaston Morris, Buick, third, 16:05. Twenty-five-mile, Harold Brinker, White, first, 26:39 1-5; Bob Murray, Buick, second, 27:04 3-5; Steve Elmore, Stutz, third, 27:07 1-5. Morris made an exhibition mile in 1:01 flat in an effort to meet Barney Oldfield's record of 54 1-5 for the Overland course.

Other entrants in the motor car events were A. C. Wagner in an Amplex, G. M. Edwards in a Palmer-Singer, Ben Knott in an Empire, H. M. Condit in a Hupmobile and H. N. Isenberg in an Abbott.

A fifteen-mile event started yesterday was stopped after the tenth lap on account of an accident killing one of the drivers, E. W. Swanbrough. He went into a bad curve with his Mercer so close to three bunched cars just ahead that he was blinded by the terribly heavy dust and crushed when his car swerved from the track and tore through a fence. He died on the way to the hospital.

Burman and Peugeot Star at Kalamazoo Century

KALAMAZOO, MICH., Sept. 26—Burman, driving his French Peugeot, gained new laurels in the century dash staged by the Kalamazoo people today. He took down the first prize of $1,000 in gold coin and established new world's records for 75 and 100 miles.

It cannot be said that Burman's victory was easily gained, for it was not. Eddie O'Donnell, in one of the Duesenbergs, kept up the fight and trailed the Peugeot closely. Ralph DePalma, after leading for thirty-six laps, had been forced to quit on account of trouble with his eyes. O'Donnell led Burman for fifty-nine laps, at the end of which the Duesenberg driver was forced to stop to change a flat tire. Then Bob went to the front and never was headed, although O'Donnell, after a quick tire change, made up considerable lost ground and at the finish was considerably less than a lap back of the leader.

Burman's time for the century was 1:34:29 2-5, which shot a big hole in the mark of 1:40:02 established by Ralph DePalma at Brighton Beach last Labor Day. O'Donnell also got inside DePalma's mark when he finished the race in 1:35:32 3-5. Newhouse in the Delage driven to victory by Thomas in the last 500 mile race at Indianapolis, landed third money in 1:50:45 3-5 while Jack Callaghan in the Keeton finished fourth in 1:51:14.

In addition to the above named money winners, the race was contested in by Billy Carlson in a Maxwell, Wilbur D'Alene in the Marmon, Erwin Bergdoll in the Benz, Tom Alley in a Duesenberg, Will Tidemarsh in the Great Western, Grover Bergdoll in the Erwin and "Cap" Kennedy in the Cornelian, a Kalamazoo product not much larger than a cyclecar. Still running at the finish were D'Alene, Carlson, Alley, Grover Bergdoll and Kennedy. Erwin Bergdoll went out of the contest with a broken intake valve, Tidmarsh's car was eliminated by motor troubles and DePalma was forced out when dust laden with the calcium chloride with which the surface of the track was treated got into his eyes. DePalma's accident was unusual and unfortunate and through it the contest was robbed of a leading factor.

DePalma's Hard Luck

The field was bunched the first time around and at the signal DePalma and O'Donnell shot into the lead on even terms. DePalma opened up a slight gap on O'Donnell the next time around and from that point until his accident he held the advantage, the Duesenberg driver back of him in spite of efforts on the part of O'Donnell to grab the lead. DePalma turned the twenty in 18:45, the twenty-five in 23:22, the thirty in 28:06 and the thirty-five in 32:46. On the thirty-sixth lap it was seen that something was wrong with DePalma for he slowed up on the backstretch and rolled slowly around to his pit. He climbed out, tore his goggles from his eyes, covered them with his hands and rushed for a can of water in the pit. Wearing a pair of defective goggles, the dust had worked inside and filled his eyes with calcium chloride which burned the optics. Several doctors came to DePalma and removed the irritant, but in the meantime O'Donnell and the rest had gained seven laps and Ralph's case was hopeless.

Burman, as far as appearances went, might have been running his car along steel rails laid on the track, for he never varied 3 inches from a certain path, except when he would swing to the side to pass another car. He never slowed up and the rhythm of his motors was never broken for an instant. He had no tire trouble either and following the finish of the race and after skidding around four hundred turns his Nassau tires showed no wear whatever.

The summary:

CAR	DRIVER	TIME	M.P.H.
Peugeot	Burman	1:34:29 2-5	63.6
Deusenberg	O'Donnell	1:35:32 3-5	62.9
Delage	Newhouse	1:50:45 3-5	54.2
Keeton	Callaghan	1:51:14	54
Marmon	D'Alene	Still running	
Erwin Special	G. Bergdoll	Still running

Comparing the Six With the Eight

(*Continued from page* 618)

sideration, the eight-cylinder curves would not have been so straight.

Further, considering the increasing cost of fuel, it would seem a doubtful step to lower the thermal efficiency by increasing cylinder numbers and cutting up the volume of gas into still smaller units, and by so doing increase the areas exposed to heat in proportion to cylinder volume.

Again, the decrease in cylinder bore means still smaller valves with higher frictional resistance to the inflow of gas and consequent lower volumetric efficiency.

Time to Solve Problem

When we consider the various features of vibration, thermal and volumetric efficiency, manufacturing costs and multiplicity of parts, the eight-cylinder motor either V type or all-in-line would appear from this theoretical investigation to have considerable of a task to justify itself.

If practical tests should, however, prove the eight to have an appreciable advantage over the six, there is no doubt but that American manufacturers will show no hesitation about building this type should there seem to be any considerable demand from the automobile buying public.

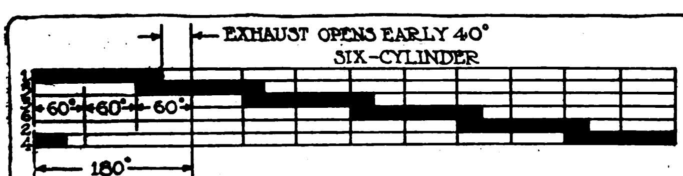

Fig. 16—Chart of overlapping power impulses which is approximately correct for a six

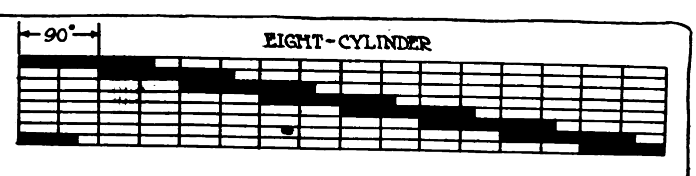

Fig. 17—Chart of overlapping power impulses for an eight drawn in the same way as Fig. 18

10,000 Chevrolets for 1915—The Chevrolet Motor Co., Flint, Mich., is planning to build at least 10,000 Chevrolet cars for the 1915 season in its Flint plants. The New York factory will take care of all of the New England States and the export business, and is expected to manufacture at least 3,000 cars. The working force will be greatly increased in both plants and within a short time the Flint plant will be turning out 50 cars a day.

Detroit Springs on Denby—The Denby Motor Truck Co., Detroit, Mich., will use springs manufactured by the Detroit Steel Products Co., Detroit.

Safety First Plant at Plainville—It is reported that the Safety First Motor Car Co. will locate its plant in Plainville, Mich., and will employ about twenty-five men to start with.

Fisher Body Adds—A two-story addition, 30 by 157 feet and to cost $10,000 will be started on the plant of the Fisher Body Co., Harper avenue and Hastings street, Detroit, Mich.

English Classes for Foreigners—The Ford Motor Co., Detroit, Mich., in co-operation with the Y. M. C. A., is establishing English classes for its foreign employees desiring to learn and to perfect themselves in that language.

Endurance Tire's New Factory—The Endurance Tire & Rubber Co. is having plans prepared for a factory to be 80 by 250 feet, one story, and of brick construction, to be erected at New Brunswick, N. J., at an estimated cost of $50,000.

Marathon Rubber Plant in St. Catharines—The ratepayers of St. Catharines, Ont., passed a by-law to grant a 5-acre site and fixed assessment of $10,000 for 10 years to the Marathon Rubber Co., Akron, O. In return the company agrees to erect buildings and a plant to cost at least $50,000 and to employ a minimum of 100 hands at the start.

Tire Plant for Buena Vista—A corporation to be known as the Williams I. X. L. Tire & Rubber Co., Buena Vista, Penn., capitalized at $300,000, has purchased a site and plans to build a plant there for the manufacture of automobile tires and commercial rubber articles.

Alpena Bids Too Low—Bids totaling only $4,500 were recorded at the sale of the property, tools, stock and outstanding accounts of the bankrupt Alpena Motor Car Co., although their total value is set at $30,000. The bids were not accepted and another sale probably will be ordered.

Elbert Co. Locates Plant—The Elbert Motor Car Co., a recent incorporation in Seattle, Wash., has located its plant at 2012 Fifteenth avenue, West, that city. In addition to manufacturing a cyclecar this company will also build a light delivery car with a carrying capacity of 500 pounds.

Auto-Rebuilding Co. Increases Output—The Auto-Rebuilding Co., Victoria, B. C., manufacturer of automobile bodies, wheels, springs, engines, etc., has been taken over by a syndicate in that city with increased powers and larger working capital. The output of the plant will be increased.

Ahlberg Bearing Co. Opens Plant—The Ahlberg Bearing Co., Chicago, Ill., has opened an office and factory in Los Angeles, Cal. This company specializes in regrinding annular ball bearings. Karl E. Ahlberg, president of the company, has taken charge of the company's interests in Los Angeles and is personally superintending the installation of the machinery.

Occupies Reliance Truck Co.—Recently the American Malleables Co., Lancaster, N. Y., secured the plant formerly occupied in Owosso, Mich., by the Reliance Motor Truck Co., and is now manufacturing all kinds of malleable iron castings, specializing in automobile work. The company contemplates operating another plant in Flint, Mich., within the next year.

Standard Welding's Third Addition—The Standard Welding Co., Cleveland, O., is building its third large addition of the year to its plant. The newest structure is of structural iron, with corrugated asbestos, metal reinforced roofing and siding. The dimensions are 60 by 240 by 30 feet high. The new building is to be devoted entirely to the storage of rims and will accommodate approximately 100,000 rims.

Chevrolet Dealers Visit Factory—About sixty Indiana dealers for the Chevrolet accompanied William J. Small, state distributor, on a visit to the factory at Flint, Mich., last week. Before going to the factory, 2 days were spent in Detroit, followed by 2 days at the factory, where there were a number of special entertainment features. The dealers drove home new cars, thus opening the 1915 season for the Chevrolet in Indiana.

Jeffrey's Cold Weather Tests in Summer—The Thomas B. Jeffery Co. has installed in the works at Kenosha, Wis., a refrigerating plant for the purpose of making cold weather tests on Jeffery carbureters, batteries and motors. In 1 hour after starting the refrigerating machinery it is possible to get a temperature of from 8 to 10 degrees below zero. The room in which this outfit is installed will accommodate one of the largest Jeffrey models and leaves plenty of room for men to work on the car. This device has been installed by the Jeffrey company so that summer experiments can be conducted under winter conditions.

The Automobile Calendar

Oct. 3-10........Cincinnati, O., Show.
Oct. 3...........Fresno, Cal., Track Meet, Fresno Co., Agricultural Assn.
Oct. 4...........St. Louis, Mo., Automobile Show, Auto Manufacturers' and Dealers' Assn.
Oct. 5-12.........St. Louis, Mo., Show, Forest Park Highlands.
Oct. 7-8-9-10.....Detroit, Mich., First Truck Convention of Motor Truck Manufacturers', Dealers' and Owners' Organization; promoter, Motor Truck Club of America.
Oct. 7-17........New York City Electric Vehicle Show, Grand Central Palace.
Oct. 10..........Medford, Mass., Track for Light Cars, Combination Park.
Oct. 10-17........Boston, Mass., New England Light Car and Cyclecar Show, Horticultural Hall.
Oct. 17..........Los Angeles, Cal., Show, Shrine Auditorium.
Oct. 17-23........Los Angeles, Cal., Show, Shrine Auditorium.
Oct. 17-24........Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 17-Nov. 1....Dallas, Tex., Show, State Fair Grounds, Dallas Automobile Dealers' Assn.
Oct. 19, 20, 21....Philadelphia, Pa., Elec. Veh. Assn's Convention.
Oct. 19-26........Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28..........New York City, Commercial Tercentenary Celebration.
Oct. 28-31........Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov.............El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 8-9.........El. Paso to Phoenix, Ariz., Automobile Race.
Nov. 8-11.........Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 26..........Corona, Cal., Road Race, Corona Auto Assn.
Dec. 1-4.........New York City, Annual Meeting of the American Society of Mechanical Engineers.
Jan. 2-9.........New York City, Annual Automobile Show, Grand Central Palace
Jan. 3-10........Buenos-Aires, Argentina, Grand Prize of Argentina.
Jan. 9-16........Philadelphia Automobile Show.
Jan. 23-30.......Chicago, Ill., Automobile Show, First Regiment Armory.
Jan. 30-Feb. 6....Minneapolis, Minn., Show, National Guard Armory, Minneapolis Automobile Trade Assn.
Feb. 15-20.......Omaha, Neb., Show, Auditorium, C. G. Powell.
Feb. 22..........San Francisco, Cal., Vanderbilt Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Mar. 6-13........Boston, Mass., Show, Mechanics Bldg., Boston Auto Dealers Assn. Boston Commercial Motor Veh. Assn.
Mar. 7...........San Francisco, Cal., Panama-Pacific Exposition, Grand Prize Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Mar. 14..........San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

The Week in  the Industry

Motor Men in New Roles

NEW SCRIPPS-BOOTH APPOINTMENTS — R. H. La Porte, formerly with the H. H. Franklin Mfg. Co. as Eastern sales representative, has joined the selling force of the Scripps-Booth Co., Detroit, Mich., and will appoint agents in the Eastern and Southern States. A. D. Caldwell, formerly with the Hupp Motor Car Co., Detroit, as sales representative, has joined the selling organization of the Scripps-Booth Co., and will appoint agents in the Middle, Western and Pacific States.

Menzies Sales Manager—C. M. Menzies has joined the Northwest Auto Co., Portland, Ore., as sales manager for the Cole and Reo.

Sickles Hyatt Roller Bearing Engineer—E. C. Sickles has been engaged as works engineer for the Hyatt Roller Bearing Co., Newark, N. J.

Warren Portland Studebaker Manager—D. C. Warren is the newly appointed sales manager for the Oregon Motor Car Co., Studebaker distributor, at Portland, Ore.

Merz Quits Racing—Charles Merz has quit racing to join the Findeisen & Kropf Mfg. Co., Chicago, Ill. He will represent the firm in the engineering department.

Rhodes Abbott Sales Manager—D. M. Rhodes has been appointed sales manager of the local branch of the Abbott Motor Co., at 467 Woodward avenue, Detroit, Mich.

Lloyd Treasurer—C. W. Lloyd has been made treasurer and appointed retail sales manager of the E. C. Johnson Co., Philadelphia, Pa., distributor for the Reo and Premier cars.

Gilpin Heads Milwaukee Ford—Ford business in Milwaukee, Wis., is now in charge of a direct factory representative, A. W. L. Gilpin, who has headed the Chicago branch for some years.

Mitchell Joins Barger—T. H. Mitchell has bought half the interest of L. E. Barger in the Abbott Motor Sales Co., Toledo, O. Hereafter the business will be conducted as a partnership.

McDonald Chalmers Manager—H. R. McDonald has accepted the management of the Oakland (Cal.) branch for Chalmers cars, operated by the Western Motor Car Co., of San Francisco.

Miller N. Y. Winton Sales Manager—H. J. C. Miller is sales manager of the Winton Motor Car Co., New York City. He has been a member of the Winton sales force in that city since 1906.

Sommer Allen Superintendent—L. A. Sommer, president of the Sommer Motor Co., Bucyrus, O., has been elected general superintendent of the Allen Motor Co., Fostoria, O., maker of the Allen car.

Farrington Resigns from Power Wagon—S. A. Farrington has resigned his position as editor of *Power Wagon*, Chicago, Ill., to accept the position of publicity manager for the Thomas B. Jeffrey Co., Kenosha, Wis. He is succeeded by S. A. Phillips, formerly technical editor of *Power Wagon*.

Sowers Now Manager—J. L. Judd, who managed the Jackson branch in Boston for some years, resigned recently, and A. H. Sowers, for a long time sales manager of the firm, was appointed to fill the vacancy.

Gray J-M Manager—H. W. Gray, who has been in the automobile business in St. Louis for the past 6 years, has been appointed manager of the accessories department of the H. W. Johns-Manville Co. there.

Fred Merz in Repair Business—The Guarantee Auto Repair Co. has begun business in Indianapolis and will make a specialty of rebuilding and overhauling motor cars. The company is owned by Fred P. Merz.

Buckley Ford Retail Manager—H. M. Buckley, who started with the Ford Motor Co. in Detroit in 1909 as a machinist, has been appointed manager of the retail sales department of the Ford Chicago branch.

Gibson Takes on Further Work—B. S. Gibson, Jr., formerly assistant manager of the A. G. Spaulding Bros. agency for Stevens-Duryea cars in New York City, is now in charge of the Brooklyn and Long Island business.

Allen Promoter — C. Louis Allen, formerly automobile sales manager of the Pyrene Mfg. Co., New York City, maker of the Pyrene hand fire extinguisher, has been promoted to the position of general sales manager.

Jossman Joins Chevrolet—H. R. Jossman, who was formerly traveling representative in the State of Michigan for the Oakland Motor Car Co., Pontiac, Mich., has a similar position with the Chevrolet Motor Co., Flint, Mich.

Fuller Gets Nomination—Alvan T. Fuller, who handles the Packard in Eastern Massachusetts, was nominated for representative to the Bay State legislature on the Progressive ticket last week in Malden, Mass., where he lives.

Weise Joins Winton—John S. Weise, for several years manager of the United States Tire & Rubber Co.'s branch at Los Angeles, Cal., has been appointed sales manager of the Los Angeles factory branch of the Winton Motor Car Co.

Homan Resigns from Overland—C. C. Homan has resigned as purchasing agent of the Willys-Overland Co., Toledo, O. H. V. Hawk has been appointed general purchasing agent of that company, the Gramm Motor Truck Co. and the Garford Co.

Shutt Back in Boston—W. H. Shutt, formerly manager of the H. J. Koehler Co., Boston, Mass., who went to New York some months ago, has been sent back to assume charge in his old position to push the sale of Grant cars in New England.

Johnson Klaxon's Detroit Representative—A permanent office has been opened in room 1317-1319 Dime Bank Bldg., Detroit, Mich., by the Lovell-McConnell Mfg. Co., Newark, N. J. Charles Johnson, special representative from the home office, is in charge.

Trombley Sales Manager—D. M. Trombley has become general sales manager of the De Luxe Automobile Co., St. Louis, Mo. He was formerly with the Pathfinder Motor Car Co., also the Cole Motor Car Co., of Indianapolis, and the Cole Motor Car Co., of Missouri.

Holleyhead Federal District Sales Manager—A. F. Holleyhead has been appointed district sales manager of the Federal Motor Truck Co., with headquarters in Chicago, Ill. Mr. Holleyhead was formerly manager of the Detroit branch of the Gibney Tire Co.

Bond District Sales Manager—W. W. Bond has been appointed district sales manager for the states of Indiana and Kentucky, for the Detroit Electric Sales Co., Indianapolis, Ind., agent for the Detroit electrics. His headquarters will be at Meridian and Walnut streets, Indianapolis.

Kjeldsen with Holdbrook—S. J. Kjeldsen, who has been associated with the foreign car business in this country for some time, has joined the Holbrook Co., New York City, builder of automobile bodies.

Jackson Sole Owner—J. R. Jackson, during the last three years manager of the Stratton-Woodcock Automobile Co., Grand Rapids, Mich., is now sole owner of that concern, having bought out the interest of the other stockholders. A new salesroom is to be opened by him opposite the present agency and the Paige-Detroit will be handled from there.

Westcott Men Promoted—When H. G. Root of Springfield, O., succeeded H. L. Ashley as secretary-treasurer and general manager of the Westcott Motor Car Co., Richmond, Ind., G. F. McCurty, who had held the position of sales manager, became assistant general manager, while H. P. Mammon formerly district sales manager for the Cole Motor Car Co., in the central states, became sales manager of the Westcott company.

Chandler Change in Cal.—A change has taken place in the handling of the Chandler cars in California. The Peacock Motor Sales Co., Los Angeles, Cal., has been appointed distributor for Northern California, Nevada and the Hawaiian Islands, while the Pearson Motor Car Co. will handle the car in San Francisco. George A. Peacock is general sales manager there and Roy B. Alexander is manager in San Francisco. The other officers are: George Pearson, Jr., and E. L. Peacock.

Prominent Detroiters Are Bank Directors—Four of the best known men in the automobile business in Detroit, Mich., are members of the Board of Directors of the Merchants National Bank, which was recently organized here. These men are: Walter O. Briggs, president of the Briggs Mfg. Co.; Hugh Chalmers, president of the Chalmers Motor Co.; Horace E. Dodge, vice-president and general manager of Dodge Bros., and Eugene W. Lewis, secretary-treasurer of the Timken-Detroit Axle Co.

Accessories for the Automobilist

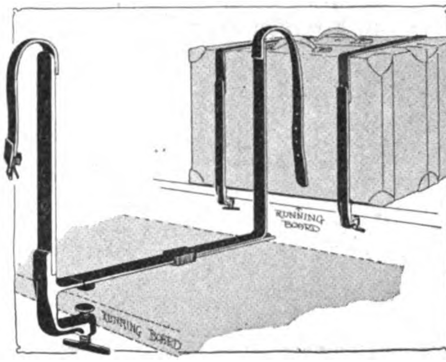

Fig. 5—Asch suitcase carrier

SPARTON Warning Signal—A hand-operated warning signal, Fig. 1, at the unusual price of $5 is now offered by the Sparks-Withington Co., Jackson, Mich. This represents a reduction of $3. A similar horn with a straight trumpet is also offered for $4.25. Both these horns are made so that they can be easily attached to the car, and they are well finished in black enamel and brass.

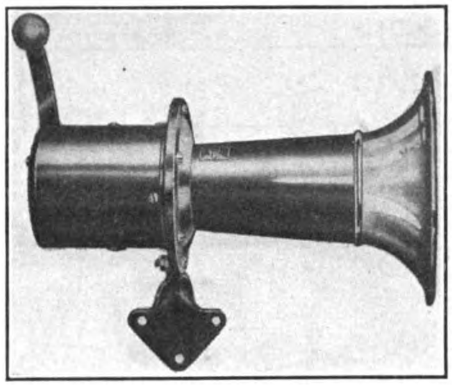

Fig. 1—Sparton hand-operated warning signal

Multiple Cone Clutch—A multiple cone clutch whose special features are ease of engagement and long life is shown in Figs. 2 and 3. In the former illustration, which is a part section, the construction is shown very clearly. The three cones are all on the one four-splined shaft. When the clutch collar, indicated, is pushed to the left, which is out, the smaller cone is disengaged. When this is moved about 3-16 inch further its hub comes into contact with the hub of the middle cone and this cone is then forced out. In like manner the third cone is disengaged by the further movement of the clutch collar. These cones are engaged by springs of different strengths, the largest cone having the strongest spring.

When the clutch is to be engaged, the largest cone goes in first and the others follow in order. In this way a smooth and gradual clutching action is obtained. The facing is plain metal and the clutch runs in oil. The taper is 4 degrees and the overall length is 11⅞ inches. The clutch is designed for 35 horsepower at 1600 revolutions per minute. It is manufactured by the Automatic Gas Motor Co., Indianapolis, Ind.

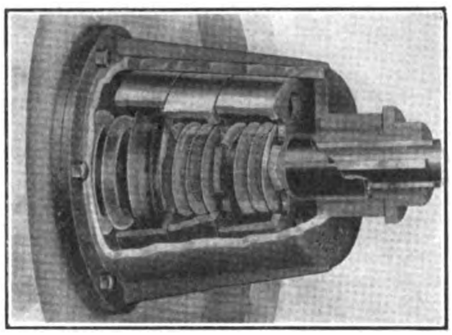

Fig. 2—Phanton view of Multiple cone clutch

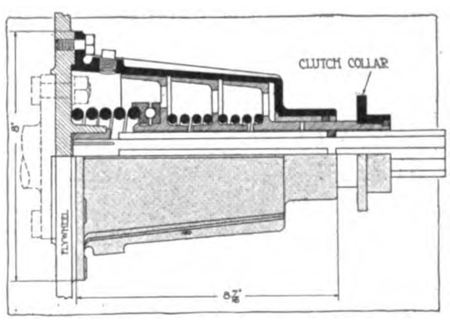

Fig. 3—Part section through Multiple cone clutch

Asch Hose Clamp—A simple and effective instrument for making hose clamps out of plain iron wire is offered by Asch & Co., 1779 Broadway, New York City. This device is shown in Fig. 4. The coupling is made by taking a piece of stout wire and bending it into a U shape and then slipping the free ends of the wire through the U as shown at the top, right. The tool is attached as shown, the ends of the wire being wound around the pins as indicated. The wire is then drawn tight by screwing up on the wing nut and when this is accomplished the tool is bent over to the right and the wire is cut off close to the hose leaving the hose clamp completed as shown at the left at the bottom. The price of this device is —

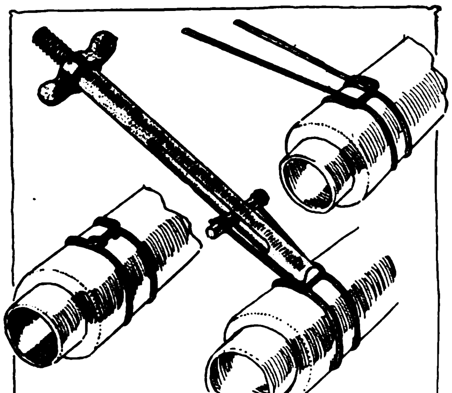

Fig. 4—Asch hose-clamping tool

Asch Suit Case Carrier—A handy device that should be appreciated by tourists is the suit case carrier shown in Fig. 5. It enables one or two suit cases or a small trunk to be solidly strapped to any running board. The carrier is adjustable so that it may be put in place instantly and changed from one car to the other as desired. The method of attachment is very simple. There is a screw clamp which can be tightened by hand as shown. The price per pair is $3. They are distributed by Asch & Co., 1779 Broadway, New York City.

Holden Easybak Cushion—To fill in the little space at the base of the seat back, the Holden Mfg. Co., of St. Paul, Minn., is advancing the Easybak Cushion, which it claims makes the driver's seat like a morris chair. It allows the driver to rest while stretching out his feet to control the brake and clutch pedals and obviates the possibility of backache.

Carleton Electric Generator—To furnish current for automobile lighting, the Carleton Co., Boston, Mass., has placed on the market the Carleton electric generator, which, at the rate of 1,800 revolutions per minute, can provide sufficient power to supply lamps of 48 candlepower. This requires a current of 6 volts and 8 amperes. This is more than sufficient to supply any automobile. The generator sells for $15.

Grant-Lees Gearset—For cars weighing not over 1,600 pounds, the Grant-Lees Co., of Cleveland, Ohio, will have ready for delivery in October a new gearset. The case is aluminum, the gears of 3½ and the shafts of 1 per cent. nickel steel. This is made for cars carrying a motor of bore and stroke 3¼ by 5, and capable of developing 25 horsepower at 1,600 revolutions per minute.

Sewell Cushion Wheels—For motor trucks having solid tires, and for many that now carry pneumatic tires, the Sewell Cushion Wheel, made by the Sewell Cushion Wheel Co., Detroit, Mich., is advanced as economically effective in taking away the jars and jolts, while reducing tire costs. The principle of the wheel, Fig. 6, is an outer and inner rim, between which is a rubber cushion. At the side is a rubber flange, which is held in place by two steel bands. This serves

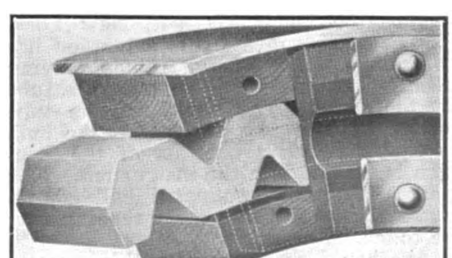

Fig. 6—Sewell cushion wheel for trucks

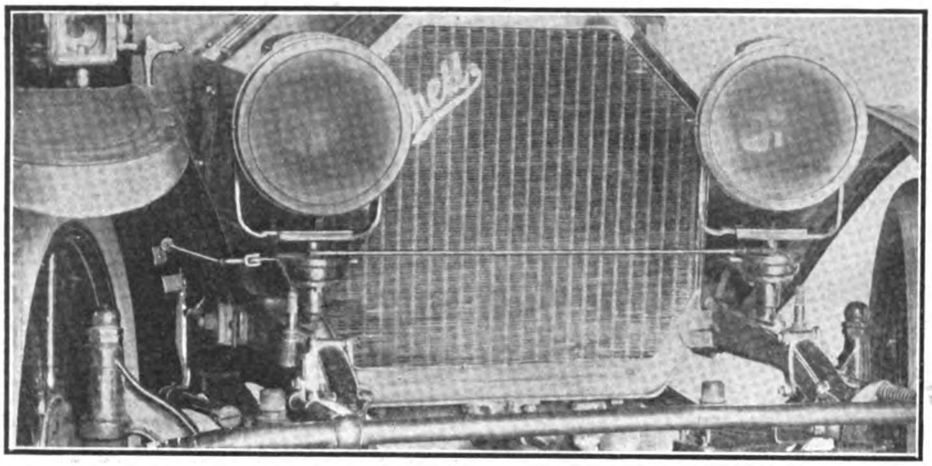

Fig. 7—Hughes turning headlights

to keep the rubber flange from bulging.

Hughes Turning Headlights—Fig. 7 shows a simple device invented by David Hughes, of Racine, Wis., for turning the headlights of the car automatically with the steering gear. Small movements do not make any difference in the straight, forward position of the lights, but further movement of the front wheels to the left or right points the headlights in the direction that the car is turning, so that the road is properly illuminated. The device can be installed on almost any make of car.

Davis Friction Drive—A friction transmission of unusual design has been brought out by the Davis Car Co., Seattle, Wash. It is illustrated, in Fig. 8, and it will be noted that the reduction is obtained by means of two pairs of cones. The drive cones have large faces over which the driven cones slide in and out to obtain the different reductions. It must be noted that, as the pair of driven cones move in to give high gear, the driving cones must move out. This is accomplished by means of the four arms pivoted at A. The pressure of the cones is adjusted by means of the two levers B. Since no provision is made for a differential, compensation is secured when rounding corners by the slippage of the pair of bevels that drive the inner wheels. The use of four cones instead of two also has the advantage that with a given permissible size of cones the wear is cut in half.

It is planned to assemble a light car weighing 1,200 pounds and equip it with this transmission.

Michelin Tire Poster—The Michelin Co. is sending out a poster which bears a humorous picture of the "Michelin Man" having removed from his anatomy a tire to aid a motorist who has evidently had a serious blow-out. The poster is 21 by 29 inches. It may be secured from the Michelin Co., Milltown, N. J., by sending 10 cents in stamps.

Weinhagen Hydrometer—H. Weinhagen, 160 Leonard street, New York, has brought out a hydrometer for use in battery work, this instrument having a bulb attachment at one end and a tube at the other. The mouth of the tube is immersed in the electrolyte, the bulb is squeezed and a quantity of the solution is carried into the instrument. This floats the small graduated bulb shown and in this way the gravity reading may be taken. It sells for $1.50.

Another accessory which this concern is marketing is a neat gradometer which

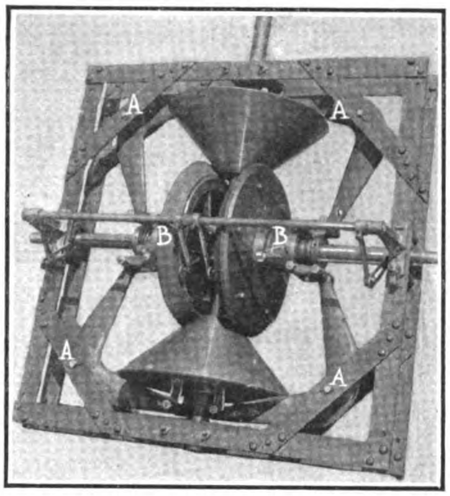

Fig. 8—Davis friction drive

is attached to some horizontal part in the front compartment, and which registers the steepness of a grade in per cent.

Pittsburgh Dirigible Searchlight—A searchlight, powerful enough to enable the occupant of a car to make out the numbers on houses, or to read small lettering on sign-posts, and which can be attached to the wind-shield in a moment, is being advanced by the Pittsburgh Electric Specialties Co., Pittsburgh, Pa. The searchlight can be attached to the battery or lighting system. It is operated on a universal and can be turned in any direction. With it one can look for trouble in the engine, at the same time having a more powerful light than is ordinarily obtained in a light made for this purpose.

Brazelton Headlights—An odd type of headlight has been introduced by G. T. Brazelton, Birmingham, Ala., which is built into the radiator and has shutters at the sides which permit the light to be thrown to the sides of the road. The shutters are operated from the driver's seat and the light coming through the shutters is thrown above the fenders owing to the high position of the lamps.

Hoosier Tandem Master Vibrator—The feature of the Hoosier master vibrator, shown in Fig. 9, is that two pairs of platinum contacts are employed instead of one, as ordinarily. These are connected so only one operates at a time, however. Should the operating pair stick the other pair will take up the work automatically.

The Hoosier Tandem, as it is called, is housed in a neat mahogany box with a substantial switch. It is manufactured by the Hoosier Oil Co., South Bend, Ind., and sells for $15.

Chaney Dimmer—A dash switch, Fig. 10, that graduates the intensity of the light from high to low and can be worked either with the hand or the foot, is made by the L. F. Chaney Co., Springfield, O. In city driving the light is kept low with small current consumption. In emergencies, where full power is needed, a touch on the handle brings back the full search light efficiency. On dark country roads, in isolated territories, the full search light glare is essential to the safety of the driver and the occupants of the car.

Cozy Cab Top for Fords—A storm-proof top for 1913 and 1914 Ford runabouts has been brought out by the Fouts & Hunter Co., Terre Haute, Ind., under the name of the Cozy Cab top. This top is easily detachable and adjustable in a very short time. The Cozy Cab has a front window which is hinged at the top and swings up out of the way when not in use. The door curtains, made of rubber covered duck, roll up automatically around a metal spring roller concealed in a housing on each side of the front window. The front window takes the place of the ordinary windshield, but uses the holes employed for holding the latter. The side panels, one on each side of the seat, are held by the irons which secure the folding top. These panels fit around the edge of the seat. It sells for $50.

Fig. 9—Left—Hoosier Tandem Master Vibrator for Fords.

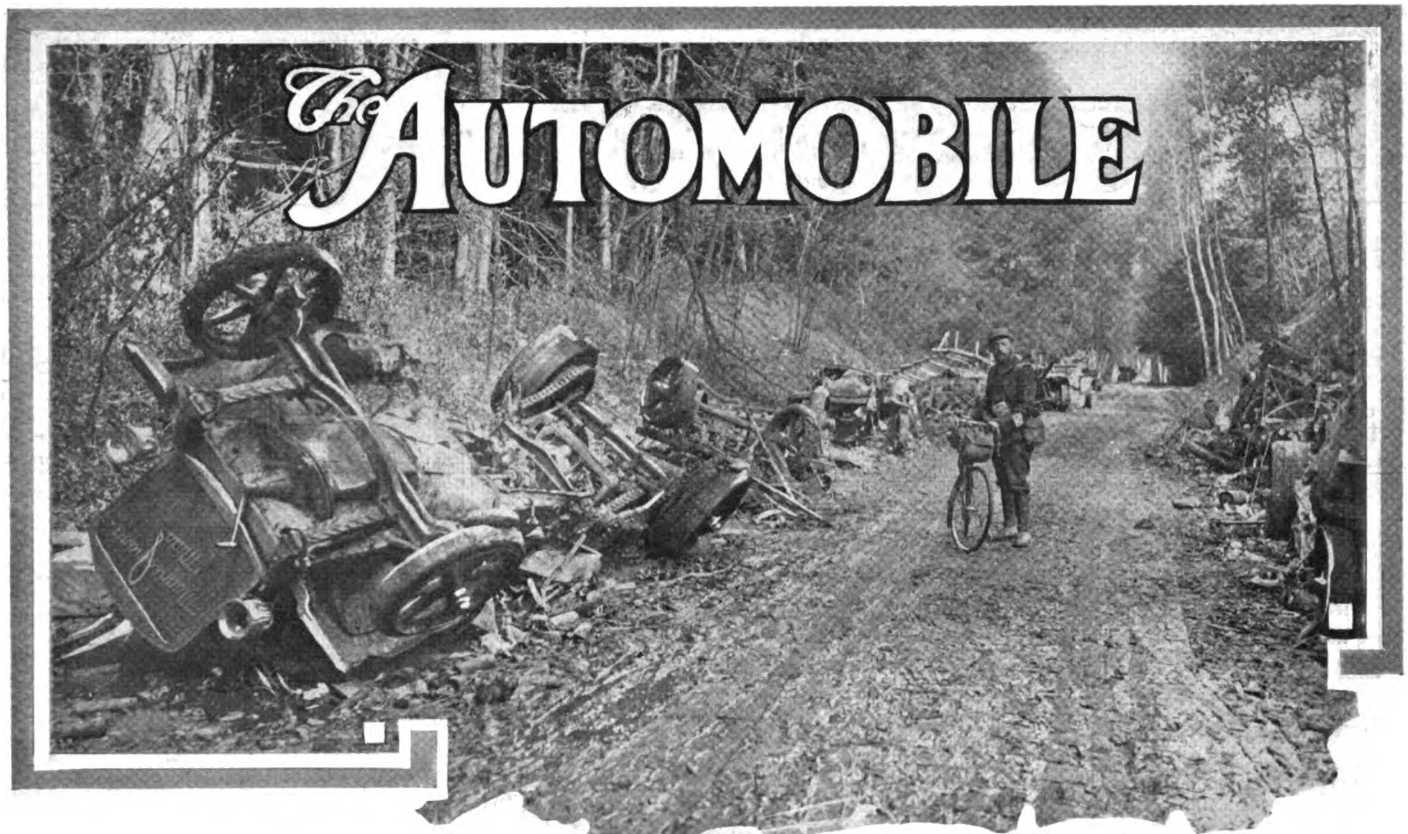
VOL. XXXI NEW YORK—THURSDAY, OCTOBER 8, 1914—CHICAGO NO. 15



A German motor convoy attacked and destroyed by French troops in the forest of Villers-Cotteret. A rifle shot killed the driver of the first truck and it capsized and the rest of the vehicles were piled up behind it. Fire broke out and destroyed the entire fleet

With a Car at the Front

Tremendous Work Done by Cars and Motor Trucks in European War—Changing Tires Under Fire—A Night Dash Over Battlefields

By W. F. Bradley,
Special Correspondent of THE AUTOMOBILE *with the Allied Armies in France*

PARIS, Sept. 25—We speak and write of the importance of the role played by automobiles in this great war, but no man, who has not been on active service, can appreciate to the full the work done by mechanical transport. The opportunity presented itself to go on active service as a motor car driver, doing the same work as well-known race drivers and hundreds, indeed thousands of more humble motorists. I accepted this offer, and at the present moment am wearing the British uniform, driving officers from the base to army headquarters, from headquarters to the firing line—doing any kind of work which may be required. This is the story of a spell of service, a period in which days were lost count of, for the completion of the task and not the setting of the sun decided that rest should be taken.

Officers Use Cars Only

I was given orders to report at the depot 6 miles away within half an hour. The first work was to carry officers in the district of Paris and to the army base. Officers never make use of the railway—unless they are prisoners. The only rapid means of locomotion is the automobile. The trip from Paris to the nearest point of the firing line can be made in 3 to 4 hours with a fast car. The average time on the train is from 20 to 23 hours.

While military men are making the greatest possible use of cars, civilians are being restricted to the utmost. Within the zone of the armies it is absolutely impossible for a civilian automobile to penetrate. Newspaper men in particular have made wily and determined efforts to break through, but without success. The seizure of the car and the return of the occupants on foot, escorted by gendarmes, effectively puts a stop to any such schemes.

The freedom of the main roads from all other kinds of traffic and the right of way which the military man enjoys make it possible to maintain a very high average rate of speed. A pace of 30 or 40 miles an hour can be set and maintained for hour after hour, the only necessity for slackening being on turns or when army convoys are met.

Right—M. Michelat, chief engineer of the Delage company, now serving as an automobile driver with the French army. His duty is driving officers to and from headquarters and to the firing line

Upper left—English motor truck passing through one of the Marne towns while the battle of the Marne was in progress

Lower left—A Delage car on the firing line. Note the German caps which the French soldiers have put on for a prank. The men are always ready for a bit of fun .

After a full day's work in and around Paris, I was given the order to drive to the headquarters of the British army in the field. Paris is a fortified city, with gates closed and breastworks outside the gates. Civilians driving cars only get through with great difficulty; military cars have a right of way. Five miles from the city walls a deserted country is entered. All the troops are at the front and most of the civilians have fled. From time to time a wrecked automobile is seen by the roadside. When a machine breaks down under war conditions it has to be repaired on the spot or abandoned. There are no resources other than those possessed by the driver, and if he is unable to carry out the repair the best plan is to strip the chassis and leave it. It is almost painful to see high grade cars rotting and rusting by the roadside when a little unobtainable assistance could have saved them.

Most of the cars seen on the road are high-grade machines bearing all the evidences of hard and continuous work. In a little village where I was held up for a few seconds a handsome Rolls-Royce with a costly boat type body appeared. A German helmet was tied to the radiator cap, the body was thickly coated with mud and tied around the car were cans of gasoline and boxes with provisions.

Truck in Artillery Zone

The battle of the Marne had come to a close about a week before I ran through this district. But all the ravages of war were to be seen. At the town of Meaux the half of a rickety bridge spanned the Marne. This point had been under heavy fire, for the houses at the approach to the bridge were in ruins, and an English motor truck, which had somehow or other got into the line of fire, was in such a condition that it was not even worth the attention of the junk dealer.

All the barges in the river at this point had been sunk. Between Meaux and Chateau-Thierry, about 40 miles up the river, not a single bridge has been left intact. At one of these towns on the River Marne the bridge has been blown up by the French at 2 p. m. At 2 o'clock the following morning German officers approached this bridge in a Benz limousine. Not knowing that it had been demolished, they rushed across at high speed to fall to an instant death in the water.

After crossing the Marne at Meaux it was discovered that we could not get back to the north side without making a wide detour to Chateau-Thierry, a town famous years ago for its hill-climbing competitions. Consequently we swung round and recrossed the Meaux bridge, making a detour on the north bank to Chateau-Thierry. This brought us through a big portion of the Marne battlefield. All the dead and wounded men had been removed, but horses still lay in the fields and on the roadside.

But what most impressed one as a tourist was the utter untidiness of the whole countryside. One hill had been under heavy shell fire. Big trees had been cut through by shell, innumerable branches had been carried away, every telegraph pole was broken and telegraph wires hung stragglingly. In the fields, where there were not actual signs of fighting thousands of cans and bottles lay around. There were spent shells, also unspent shells mounted in wicker baskets. In one field a big heap of soldiers' equipment was rotting under sun and rain. Hay ricks were untidy; fodder was scattered about the roadside; there were wrecked wagons in ditches. In place of the trim, grassy banks on each side of a well kept highway there was a bank of soft mud trampled by thousands of hoofs and shoes.

The Wake of War

Between the Marne and the Aisne valleys is a 30 to 40-mile stretch of country through which the German armies made their retreat after the Marne battle. This was a deserted country, not destroyed, but scoured clean of food and fodder. Despite the heavy traffic the main roads had kept in a good condition, only the side banks, which are usually trim and neat, had been trampled into a bed of mud.

As the general headquarters were approached at Fere en Tardenois conditions changed. Third and fourth class roads had to be used. As heavy rain had fallen, these roads had suffered severely. In most cases there was nothing more than a central track with deep banks of mud on each side. The conditions reminded me particularly of those in the Middle West states in America. When another car was met we each went as little into the mud as possible. When a convoy was overtaken the lorries had to be passed one by one, each passage being carried out at the risk of ditching the car.

At British Headquarters

The full extent of the motor transport service in connection with the British army was realized in the village selected by Sir John French as his headquarters. About 2 miles before reaching this village hundreds of horse-drawn army transport wagons were passed in muddy fields. It was very rarely that I saw these vehicles in actual service other than bringing up provisions for themselves.

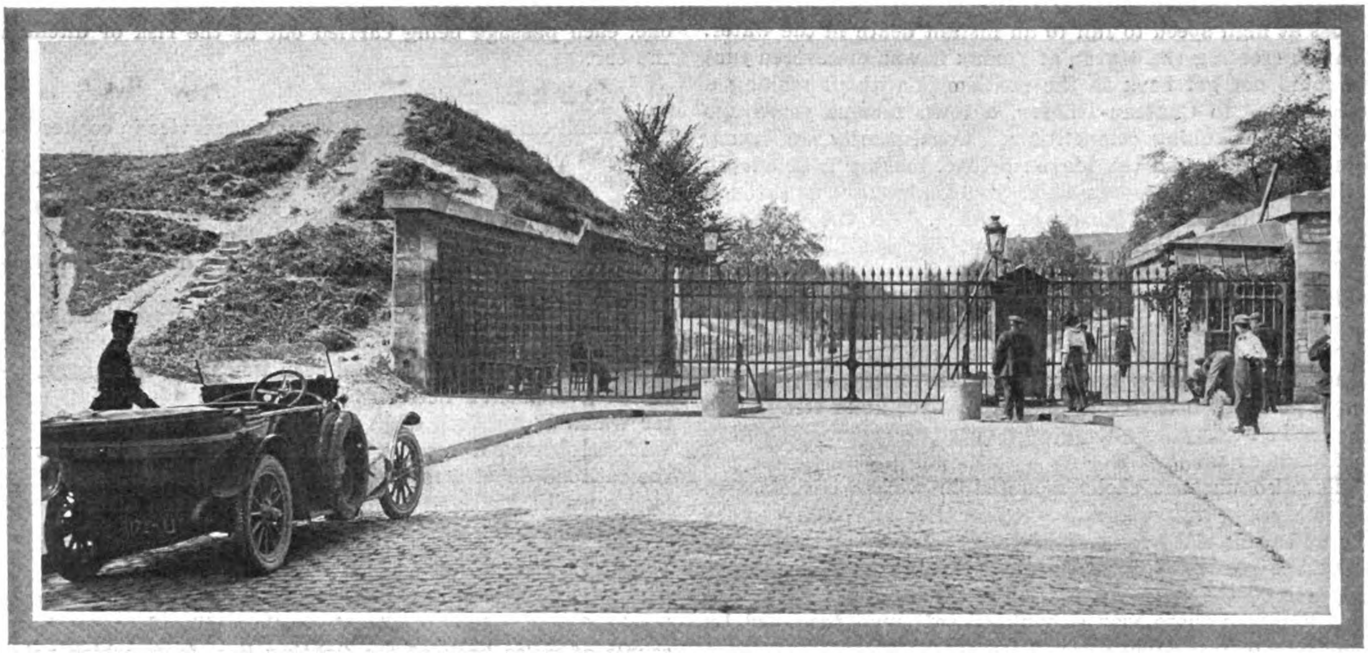
A mile outside of the town motor lorries were lined up in close formation for more than a mile. These were nearly all commercial vehicles which had been taken out of active service at a moment's notice and carried the advertising matter which forms such a distinctive note of this war. These vehicles formed a reserve called upon in rotation to go to the railroad depot a mile to the north of the town and there load up with food and ammunition to be taken direct to the firing line.

Trucks in Firing Line

Originally the military plan was to make use of motor trucks for carrying supplies from the railhead to a point a couple of miles back of the fighting line, from which point the final distribution was made to the men by horse wagons. This plan has been altered, the motor trucks now going right up to the firing line and delivering direct to the men in the trenches. This system exposes the truck to fire and has caused a few of them to be lost, but the time gained is sufficient justification for its continuance.

During the 6 or 7 weeks the war has been in progress the British motor transport service has settled down to business in a remarkable manner and is now giving results which in the opinion of all officers are amazing. The army generally is showing itself highly efficient, but the motor transport service is certainly the best of its many branches. Since the outbreak of hostilities the weaklings and unsuitable types which were pressed into service too hurriedly have been abandoned and have been replaced by new trucks supplied by English factories. Judicious classification has also been indulged in, so that 5-mile-an-hour lorries are no longer made to keep pace with 12-mile-an-hour machines.

All that remained of the German motor truck convoy destroyed in the forest of Villers-Cotteret by the French after the fire



The gates of the City of Paris are now closed and no one is allowed to pass in or out of the walls without undergoing close scrutiny and having all papers, etc., carefully inspected

No work is being done away from made roads. The absence of cross-country work is made possible by reason of the network of roads in this part of Europe. One of the chief defects of several of the English makes of lorries is the lack of clearance. I noticed several cases of rear axles designed with a view to rapid inspection and quick dismounting, but without any thought that the vehicles might have to operate on mud roads. If the war continues throughout the winter, which is likely, many of these trucks will be incapable of operating on the third and fourth class roads.

Very useful, if not indispensable, accessories are differential locks and towing hooks, front and rear. Despite careful driving a truck would sometimes get off the road into the mud. As all journeys are made in convoys, it is always possible to get the vehicle out if hooks, a rope and differential lock can be used at once. Without these accessories serious stoppages are to be feared.

Generally cooling and lubricating systems are proving satisfactory. Up to the present all the motor trucks have used gasoline only. The British army has brought its entire supply from England, either in 2-gallon cans or in big kegs, and has never had to make use of such alternative fuels as benzol and alcohol.

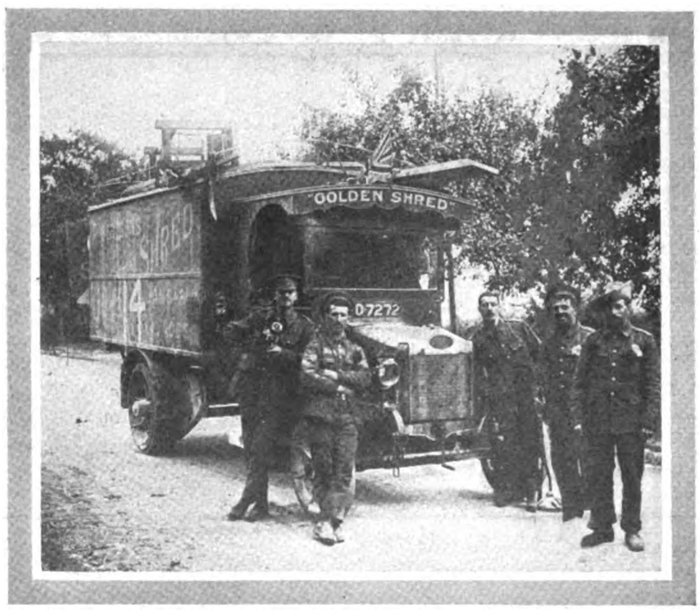
Army Headquarters Motorized

On the public square of the headquarters town there was an even greater scene of motor activity. Here were to be found 200 motor vehicles of every type. There were motorcycles, touring cars of all types, motor ambulances, trucks, omnibuses and a well-equipped motor workshop. A portion of a covered market at one end of the square formed a gasoline and oil depot. Close by was a van stocked with tires and accessories, while in the center of the square was the motor workshop. The equipment of this latter was simple but effective. The vehicle was an ordinary 4-ton chassis with a big platform body carrying a tarpaulin cover. Inside the body was a twin-cylinder Douglas motorbike motor generating current for electric lighting and for driving a lathe. Sixteen skilled mechanics were attached to this shop and at the time of my visit were working a day-and-night shift. A surprisingly extensive range of repair work was undertaken. While the equipment was sufficient to do almost any job, natural discretion was exercised; when the smash was of such a nature that it would unnecessarily tie up the resources of the shop the vehicle was abandoned rather than be repaired.

50 to 1 Officer Scheme

For every hour spent in the saddle, army officers in these days spend 50 hours in an automobile. Horses are maintained, but with the exception of cavalry officers it is a rare feature to see an officer on horseback. No particular type of touring car appears to be preferred, although English officers have a preference for a comfortable rather than a very fast car. The machine ought to be able to touch 45 miles an hour with ease and to keep up 40 miles an hour for long periods.

My own car is a Darracq of 16-horsepower rating, with no special features, but which does as good service as any other. The few special features for active service are absolute reliability, a very big range of action and adequate accommodation for tools and spares.



One of the Br'tish motor trucks at the front. Note that the advertising matter which it bore as a peaceful vehicle of commerce has not been removed. The British trucks are operated on gasoline brought from England with the troops

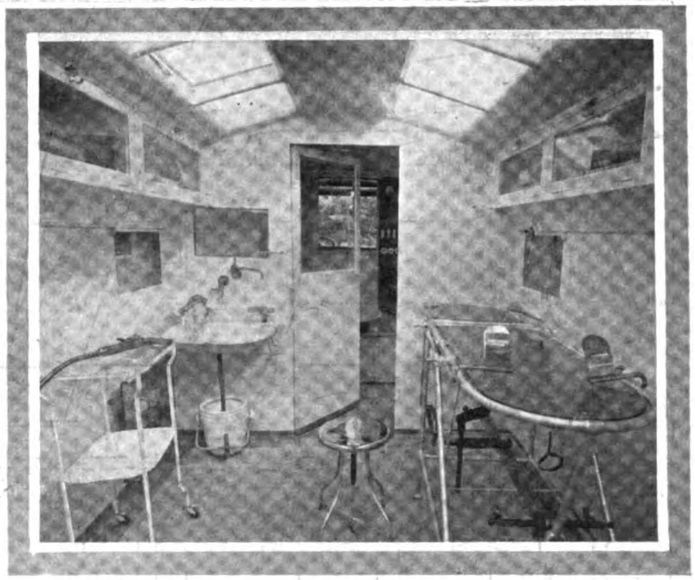
In most of the cars the gasoline tanks were too small, for in a war-devastated country it was often necessary to carry sufficient fuel for journeys of 400 to 500 miles.

An adequate oil supply was also necessary, and a car which could run very long distances without the bonnet being lifted for renewing the oil had an advantage over others.

Tires Changed Under Fire

Spares which are unnecessary in civil life are indispensable for active service, but not many cars had the necessary space for carrying these. Detachable wheels are a valuable acquisition. On one occasion when drawn up for a tire change we were fired on by German stragglers hiding in the woods behind the Allies' lines. The change was made while shots were flying. Under such circumstances there was a wonderful amount of satisfaction in knowing that the change would occupy but a few seconds, for my car was fitted with detachable wire wheels.

An efficient system of lighting is indispensable. Electric-lighting appeared to give the best results, but this system requires so little attention that here is a tendency among drivers to give it none at all, with the result that it failed them when needed.



Interior of the operating room in one of the automobile ambulances used by the French army. Note the completeness of the equipment and the immaculate cleanliness throughout

Ambulances at Fire Line

For ambulance work automobiles played just as important a role as in any other section of army activities. At this headquarters town there were a large number of 16-horse-power Wolseley fitted with light canvas bodies in which were four stretchers on rails. The stretchers were in two rows, with just sufficient room for the attendant to move between the two. These vehicles went close to the firing line, the wounded were picked off the ground by the stretcher men and the stretcher slipped into the van.

With its load of four wounded the ambulance returned to the headquarters town, which was never more than 10 miles behind the lines, and there discharged. In the town in which I am stationed the church was made use of as a hospital, the number of cases treated in this building being 2,000 on 2 successive days. After being given first attention in this temporary hospital, the officers and men were moved back to either permanent hospitals or nursing homes. A large amount of voluntary work was done in this connection.

While at the front I met R. N. Goode, of the Packard company, who was using a Packard car for carrying wounded officers from the front to the American hospital in Paris. The Paris branch of the Ford company gave important assistance in this work. Although these cars are small, they were fitted up according to a French system to carry six men in an inclined position. Light but strong hoops were fitted to the chassis, these hoops carried a waterproof cover, and the stretchers were attached in two rows of three to the hoops with a coil spring connection. Loading and unloading was not so rapid as with the British system, but there was the advantage of being able to carry two more men; further, the spring connections attenuated the road shocks.

Night Trip to Front

After spending most of the day coming from Paris to the headquarters town and in making journeys in and around the headquarters, I was ordered to be in readiness for a night trip to the firing line. At this time the battle of the Aisne was at its height; the Germans had heavily shelled the English position for 2 days and 2 nights in an endeavor to break through before the French could carry out their flanking movement. Thus, as we set out the heavy guns were booming from the heights dominating the Aisne valley, and on the banks of the river Maxims were at work. After traveling some distance under headlights, the order was given to extinguish all lights and we slipped along quietly and cautiously, descended the hill leading into the valley, crossed the pontoon bridge and finally got into touch with the troops for which we were searching. All this northern bank of the river was held by the Allies, but the Germans above were strongly opposing their advance and kept up a heavy fire on them. It was only after considerable loss that the enemy was driven out of his position on the crest of the hills.

When we returned to general headquarters it was 2 a. m. I was then allowed to go off duty. It was raining heavily, I had not been billeted, and the only place to sleep in was the rear of the car. A dozen other drivers were passing the night under similar conditions, our sleep being disturbed by the constant, steady rumble of motor trains taking ammunition to the front.

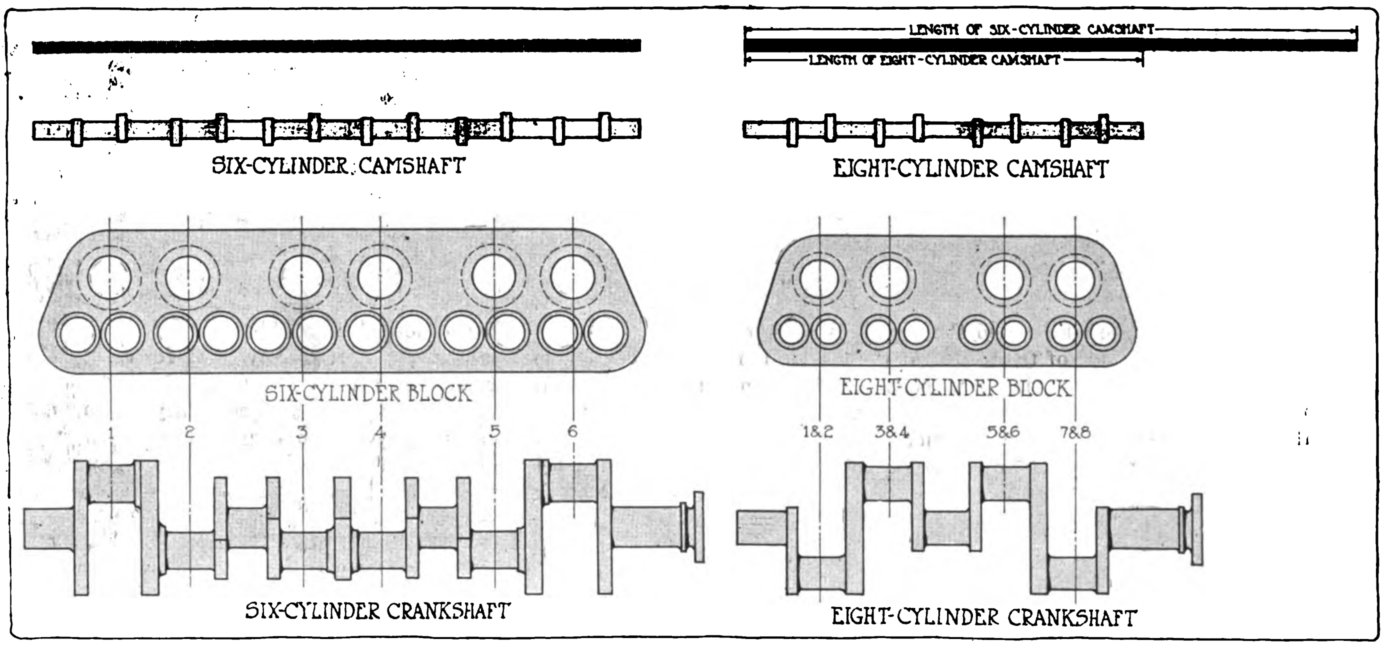
The following day was spent in carrying officers from point to point along the firing line. Passing down a straight stretch of road we were arrested by a group of peasants gesticulating wildly around a wrecked German motor van. As we pulled up they indicated that Germans were to be seen down a lane running through a wood on our left. The car was pulled up opposite the end of the lane, rapid orders were given for the motor to be kept running and the gear kept in engagement ready to slip away as quickly as possible, while rifles were got out. The men could be easily seen creeping along the hedge bottom, but as the officer was of the opinion that they were only stragglers, he fired a few shots and told me to move on. Their presence was reported to French scouts a mile down the road.

No Rest for Drivers

Most officers allow their drivers little rest. The order was given one morning to return to Paris, a 4-hour journey at high speed. After visiting military offices the order was given at 1 o'clock in the afternoon to drive to the army base 150 miles to the southwest of Paris. There was no time for a meal, and in place of the usual—or unusual—lunch, I ate sandwiches while driving. The trip was made in 4 hours.

After the business had been transacted, dinner eaten and gasoline taken aboard, a night run was made back to Paris. Only military automobiles are allowed on the roads after nightfall, and even these are stopped at the entrance to all important towns. By the aid of the headlights it was possible to maintain almost as high an average during the night as in the day. On the whole run of 150 miles only one other car was seen on the road, and naturally there were no horse vehicles.

(Continued on page 665)



Comparative dimensions of six and eight-cylinder engines designed to develop the same horsepower at the same r.p.m.

Eight-Cylinder Advantages

A Comparison With Four and Six-Cylinder Designs

D. McCall White

Late Chief Engineer Messrs. D. Napier & Son, Ltd., London, and formerly Works Manager of Messrs. Crossley Motors Ltd., Manchester, Eng., now associated with the Cadillac Motor Car Co., Detroit, Mich.

EVER since the first use of the multi-cylinder, internal-combustion engines, engineers generally have been searching for an engine which would approach the action of a turbine as nearly as possible. As evidence of this tendency one need only look at the various applications for patents in different countries, many of which embrace points relating to internal-combustion turbines.

In short, the tendency of later years has been to obtain an engine having high flexibility, freedom from vibration, combined with general sweetness and smoothness of action, with silence, and last but not least, continuous torque. These characteristics are all more or less combined in a practical manner in a carefully-designed eight-cylinder engine.

Engineering All Compromise

As every engineer knows and recognizes, all engineering designs are a matter of compromise and therefore, the careful and intelligent engineer selects and takes a line on all those prints which he hopes to obtain, not sacrificing any one point in its entirety, but molding the whole design into as successful a compromise as he is able to place before the public.

ONE CAN URGE, TECHNICALLY, MANY POINTS AGAINST EVERY TYPE OF ENGINE OR DESIGN WHICH WAS EVER PRODUCED, BUT THE ENGINEER WHO CAN DESIGN AN ARTICLE WHICH HAS THE TOTAL BEST COMBINATION OF GOOD THINGS, PRACTICALLY, HAS PRODUCED THE BEST ARTICLE FOR THE PUBLIC.

In the eight-cylinder proposition, therefore, which admittedly must be carefully designed and well manufactured, we have before us a prime mover which gives astonishing results in practically every direction one may look. The advantages are numerous and when one considers that we have practically continuous torque, owing to the fact that one cylinder fires every 90 degrees of the crank and that there are eight impulses extending over one cycle, each impulse lasting theoretically 75 per cent. of the stroke, one can easily appreciate what this means not only as regards smooth running of the motor, but as regards the wear and tear of the tires and parts of the chassis generally.

For a given power the eight-cylinder is lighter than the six-cylinder.

The crankcase is decidedly lighter in the eight, being 25 per cent. shorter than in the six.

The crankshaft of the eight is practically the same length as that of the four-cylinder engine.

The eight-cylinder has torque 33 per cent. more uniform than that of the six.

The eight-cylinder V-engine is very adaptable for the grouping of all its accessories.

The camshaft in the eight-cylinder has eight cams as compared with twelve cams in the six-cylinder.

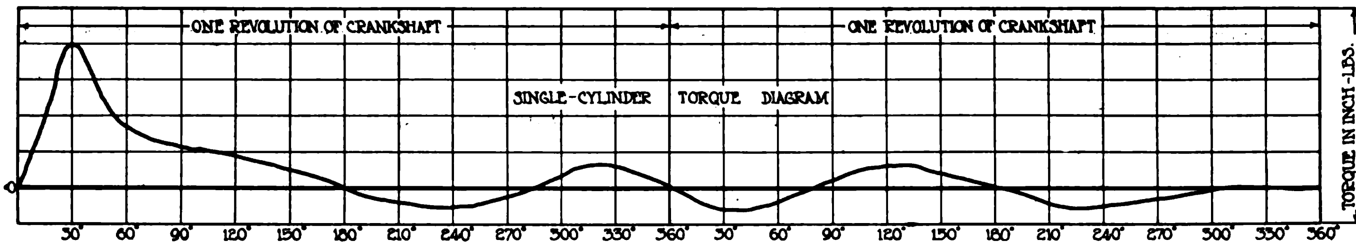
The cylinder blocks in the eight-cylinder motor weigh 15 per cent. more than those in the six.

Connecting-rods in the eight-cylinder are more expensive than in the six.

The six-cylinder motor is more expensive than the eight because of its extreme length, and the fact that it must be rigid throughout to take care of this length.

Because of the cylinders being much smaller, a higher compression can be used in the eight-cylinder than in the six.

Mechanical efficiency of eight is high, as frictional losses are not great, as the quantity of rotating bearings are no greater than they would be in a four.



Torque diagram of single-cylinder motor, showing the torque in inch-pounds on crankshaft

For a given power developed the engine is lighter than the six-cylinder by reason of the fact that the engine is no longer than a four-cylinder engine, the bore of the cylinders can be made smaller because there are more cylinders, thereby allowing the reciprocating parts such as pistons, connecting-rods and valve gear, to be made to the minimum as regards lightness.

The crankcase also is decidedly smaller and so far as length is concerned, is roughly 25 per cent. shorter than a six-cylinder engine crankcase, and is hardly, if any, longer than that of a four-cylinder engine.

Again the crankshaft is to all intents and purposes, practically the same length as that of a four-cylinder engine, which advantage is enormous not only from a weight point of view, but for reasons to be discussed later. We have also a very light flywheel on the eight-cylinder engine as compared with engines having fewer number of cylinders.

It is generally accepted that whilst there are several more values, the fact that they are smaller enables them to be well silenced and the continuous rhythm of the motor and the action of the tappets on the cams makes the turning moment practically continuous on the camshaft. In fact, this point has been generally recognized in Europe by engineers who have endeavored to steady up the uneven turning moment on the camshaft on engines by placing dummy loaded tappets at various angles on the camshaft.

Others again have a form of brake upon the camshaft to minimize this defect.

Again, the eight-cylinder engine has a crankshaft very little longer than the ordinary four-cylinder engine as previously mentioned, which in itself is a point on which great stress can be placed as one of the most serious defects which can be laid to engines which have long crankshafts is the disturbance which occurs at certain periods of engine speed. This can be overcome in a measure, by fitting a crankshaft of enormous dimensions which interferes with the mechanical efficiency of the engine as a prime mover and accounts, in common, with other points, for the difficulty many engineers have in obtaining equal power, cylinder for cylinder, from the six-cylinder engine against the four. Naturally, of course, this does not always apply, but certainly has a whole lot to do with this seeming inefficiency, when the six-cylinder is exceptionally smooth in action as regards periodic tremor. Many designers fit a damper on the front end of the six-cylinder crankshaft thus tending to absorb the periodicity. The crankshaft is undoubtedly simpler in construction and certainly is a cheaper manufacturing proposition than that of the six-cylinder engine and need only be supported upon main bearings similar to that generally employed on a good four-cylinder engine.

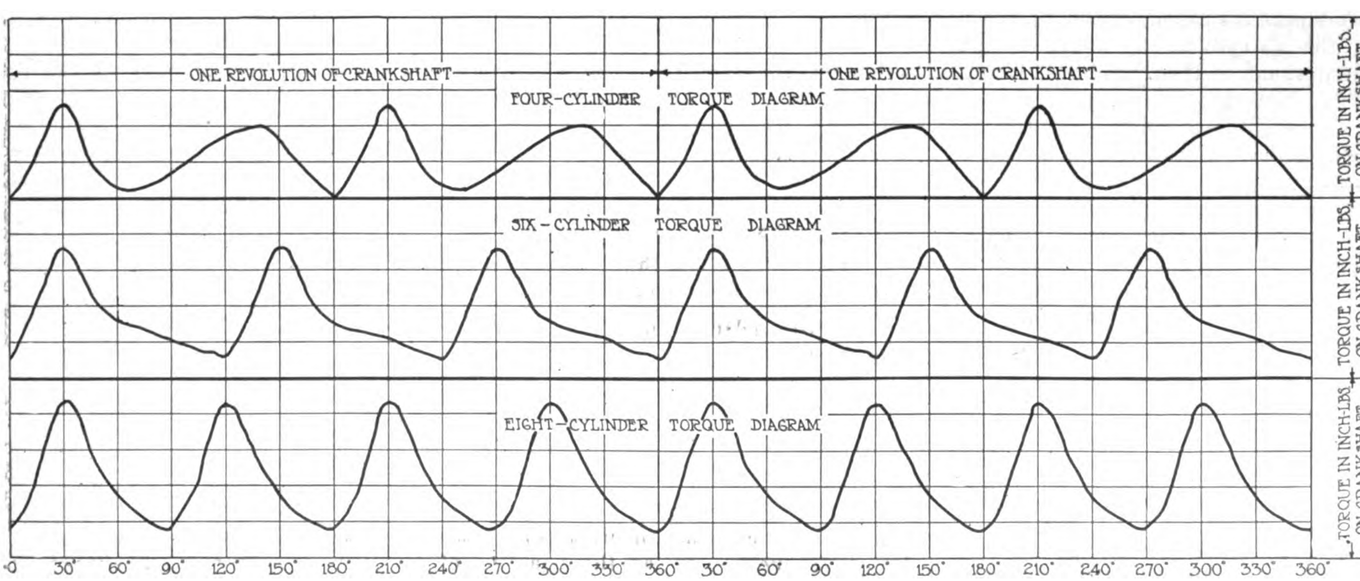
Torque 33 Per Cent. More Uniform

We have also the question of the camshaft, which should be in every engine as rigid and as free from torsional disturbance as possible. In order to demonstrate this point a comparison is made in the accompanying figure of a six and eight-cylinder camshaft, suitable for developing the same horsepower at the same speed.

Owing to the practically continuous torque of the eight-cylinder engine, the variation of the turning moment is very small, the torque being about 33 per cent. more uniform than that of the six-cylinder engine and for this reason the designer can dispense with a considerable amount of weight in the flywheel rim, as previously mentioned, which every engine must have to steady up the torque variation, storing the maximum load and giving it forth again when the load given forth becomes low, thus allowing as little speed fluctuation as possible, so that, therefore, the less the torque variation and the more frequent the impulses, the less kinetic energy required to be stored up by the flywheel.

The carburetion, which is one of the most serious and vital points in multi-cylinder engines, generally becomes a proposition as simple as the carburetion in a four-cylinder engine.

The eight, designed for high efficiency, with its magnificent



Comparative torque diagrams of four, six and eight-cylinder motors, showing increase in uniformity with added cylinders torque at low speeds, makes the necessity of changing gear practically non-existent and where one considers that flexibility and a range of speeds can be obtained from 75 revolutions per minute to from 2,800 to 3,000 revolutions per minute or more, it can be appreciated what delights are before the prospective driver when such variation can be obtained with perfect smoothness all along the scale. So smooth indeed can these engines be made, that, when the air is stationary, a pencil can be placed on end on the mudguard and the engine raced up to a high number of revolutions without any movement whatever on the part of the pencil.

The cooling also is all that could be desired as the water naturally rises to the highest and hottest parts of the cylinders, viz: the water jacket around the valves.

The engine being short, the bonnet naturally becomes so, with the result that space which would otherwise be used for an engine having cylinders all in a line, can be used for body space.

In such countries as the United States, wherever torque at low speeds is much to be desired, owing to road conditions, such an engine pulls smoothly and evenly and with great power in heavy and on direct gear and can climb and accelerate from very low speeds indeed on heavy hills.

V Design Very Adaptable

The disposition of an eight-cylinder engine when designed on the V principle leads itself nicely to the placing of the various units so necessary to the present day automobile, such as starting or lighting outfits, as well as tire pump, etc.

To illustrate comparisons clearly, the accompanying illustrations show parts of two engines, a six and an eight-cylinder, designed to develop the same horsepower at the same revolutions per minute. It will be observed that the six-cylinder engine gains as far as cylinder weight is concerned, but on the other hand, the gain is lost when one considers the weight and cost of the six-cylinder crankshaft and crankcase against the eight-cylinder crankshaft and crankcase. The same naturally applies to the camshaft.

It would be easy to go into the details and carefully analyze each point for and against these two known types of multi-cylinder engines, chief amongst these being the easy manufacturing possibilities of the eight-cylinder camshaft which has eight cams and fewer supporting bearings against the twelve cams on the six-cylinder; four throws on the crankshaft instead of six, all of which former are on one plane, while those of the latter are at 120 degrees to one another, requiring at least one more main bearing journal to support the shaft.

Regarding the matter of the cylinders, although there are two blocks the combined weight of which is greater than that of the six-cylinder by about 15 per cent., they certainly counterbalance their combined increased weight by the ease with which they can be handled in the factory.

The eight connecting-rods are more expensive than the six-cylinder owing to the fact that two more rods are used although this fact is, to some extent, balanced by there being two less crankpin end bearings.

The six-cylinder crankcase is an enormously expensive part against that of the eight-cylinder, chiefly, owing to its extreme length and the fact that it must be made so rigid to take care of this length as well as the added main bearings and camshaft bearings.

Higher Compression in Eight

Regarding the question of comparative economy, the writer is of opinion, not only theoretically, but from practical observation, that the eight-cylinder is just as economical as a four-cylinder of equal power, chiefly due to the fact that the cylinders being much smaller much higher compression can be used without distress and also to the splendid distribution of the gases.

In addition to this point it is much easier to keep the eight-cylinder engine running along without the throttle being very far open owing to its better torque, thus adding to its economy.

WITH REFERENCE TO MECHANICAL EFFICIENCY, THE V-TYPE EIGHT SHOWS UP VERY WELL INDEED AS THE FRICTIONAL LOSSES ARE NOT GREAT OWING TO THE QUANTITY OF ROTATING BEARINGS BEING NO GREATER THAN THERE WOULD BE ON A GOOD FOUR-CYLINDER ENGINE.

One large company in France has already adopted the V-type of eight-cylinder engine as standard and while they may be the first people to produce in large quantities, they are not, so far as the writer is aware, the first people to produce this type of engine.

We have the famous French eight-cylinder, V-type racing Darracq engine which put up some splendid speed tests several years ago on the Florida beach, as well as the Rolls-Royce Co., Derby, England, which produced and manufactured an eight-cylinder V-engined automobile known as the Legalimit car.

As far back as the year 1907-1908, the Daimler Motor Co, (1904) Ltd., Coventry, England, with which the writer was at that time associated, produced eight-cylinder V-type engines, the bore being 154 millimeters and the stroke 150 millimeters.

There has also been the well known eight-cylinder aviation motor known as the Antoinette as well as one or two others.

Torque Diagrams for Comparison

In the matter of torque between various engines some graphic diagrams are shown and afford an interesting comparison between single-cylinder, four-cylinder, six-cylinder and eight-cylinder engines of the same size cylinders.

The horizontal line has been divided into degrees of crank movement—each 360 degree representing one revolution, whilst, naturally, 180 degrees represents one stroke, the total length of the diagram being one complete cycle or two complete revolutions.

The vertical lines represent the torque in inch-pounds on the crankshaft.

For a single-cylinder engine, all the forces tending to twist the shaft in the positive direction are about the zero line, and all those which are negative are below the line.

It is therefore, not difficult to understand how these diagrams have been laid out, for the torque of engines, having various numbers of cylinders, is simply the torque of a single-cylinder superimposed at the correct intervals on the same crankshaft. One of the most interesting points to be noted is the positive increase of torque which occurs in a four-cylinder engine during the second third of each stroke.

Naturally, after an explosion, the torque falls off rapidly, and owing to the effect of the other pistons, it becomes very low after the crank has passed 65 degrees of a revolution. Suddenly, however, around this point the torque is increased again and actually attains a large proportion of its maximum value.

This is not due to another explosion, however, but to the curious effect of the other pistons. Thus, instead of the torque being further reduced throughout the exhaust stroke, it actually changes direction merely because of the momentum of the piston.

The same applies to the suction-stroke and compression-stroke which latter hardly shows negative torque at all.

It is these particular points which explain to a great extent the splendid results obtained from the four-cylinder engine. The six-cylinder engine undoubtedly has many points to recommend it, chief amongst which is the more or less smooth torque in comparison with engines with fewer cylinders, and has also many points in common with the eight-cylinder engine.

Counterbalancing the Crankshaft

Engineers Add Weights to Neutralize Pressure on Bearings Caused by Centrifugal Force of Masses That Are in Rotary Balance but Not in Centrifugal Balance —Mathematics Needed in Determining Size of Counterweights

By L. J. Petre
Consulting Engineer

THE idea of counterbalancing a crankshaft is usually associated with single-cylinder engines wherein the aim is elimination, or partial elimination, of vibration.

IN THE DEVELOPMENT OF THE HIGH-SPEED AUTOMOBILE ENGINE, IT HAS BEEN FOUND ADVANTAGEOUS TO COUNTERBALANCE THE CRANKSHAFT FOR THE PURPOSE OF RELIEVING THE BEARINGS OF EXCESSIVE PRESSURE DUE TO CENTRIFUGAL FORCE.

Center Bearing Suffers

The pressure on the center bearing of a three-bearing, four-throw crank may in some cases be sufficient to break down the lubricant before excessively high speed is reached. The fact that the center bearing in engines of this type do not wear as well as the end bearings has been observed by repair men.

That this difference may be largely due to the centrifugal force caused by the rapid revolution of the two intermediate crankpins together with their connecting rod big ends, would hardly be suspected. In fact, if asked, off-hand, whether there be any pressure on the main bearings of a crank of this type due to centrifugal force, the average engineer would probably answer that, inasmuch as the shaft is symmetrical and may be shown to be in running balance by means of a running balance machine, there can be no pressure of this nature. HOWEVER, WHEN THE ACTUAL PRESSURE ON EACH BEARING, DUE TO THIS CAUSE, HAS BEEN ONCE DETERMINED FOR SPEEDS BETWEEN 2,000 R.P.M. AND 3,000 R.P.M. THE SUSPICION IS READILY JUSTIFIED.

Determining Centrifugal Pressure

The process of determining this pressure consists of ascertaining:

First: Either by weighing or by calculation, the weights of each of the unbalanced* masses.

The big ends of the connecting-rods, the crankpins and usually some adjacent portions of the crankcheeks, Fig. 1 at W, X, Y and Z, are examples of unbalanced masses since they are balanced by similar parts located in other planes of revolution.

Second: The location of the center of gravity of each of these unbalanced masses.

Getting the Center of Gravity

To find the center of gravity of a flat piece of this kind, suspend it from one corner by means of a string, Fig. 2; drop a plumb line through or close to the point of support and draw across the face of the piece a line showing the position of the plumb line. Now suspend it from another corner, drop the plumb line through the point of support and the intersection of the two lines will show the location of the center of gravity.

Third: The centrifugal force due to each of these masses.

Fourth: Distribtion of these forces to each bearing.

The Necessary Calculations

The calculations necessary for determining these are as follows: Suppose that we find the weight of the big end of the connecting-rod, Fig. 4, is 3.75 pounds, and for simplicity we assume (as in this case is practically correct) that the center of gravity coincides with the center of gravity of the crankpin (see Fig. 4), that the weights of crankpin and weight W, Fig. 1, are 3.5 pounds and 3.75 pounds, also that the locations of their centers of gravity are as shown

*An *unbalanced mass* here means any weight or portion of the crank whose counterpart or counterweight does not revolve in the same plane.

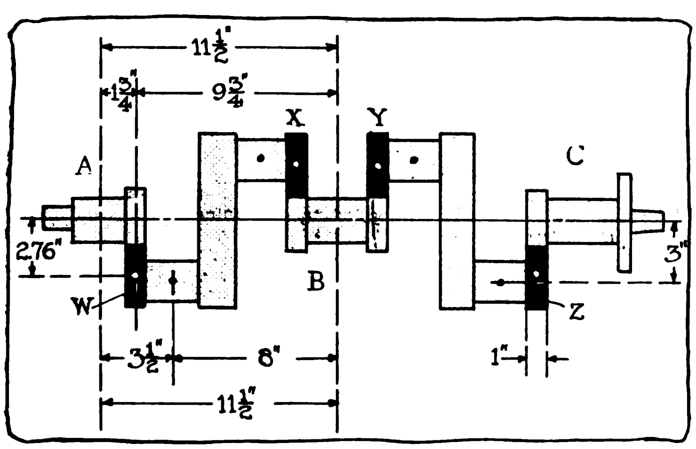


Fig. 1—Big ends of the connecting-rods, the crankpins and usually some adjacent portions of the crankcheeks at W, X, Y and Z, are examples of unbalanced masses since they are balanced by similar parts located in other planes of revolution. For instance, X and Y balance W and Z

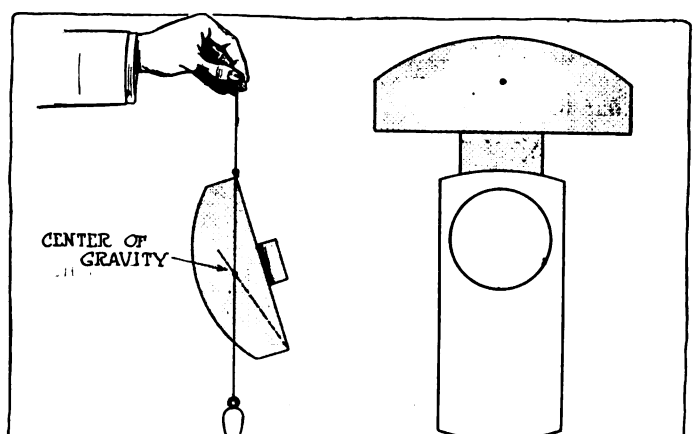

Fig. 2—To find the center of gravity of a flat piece suspend it from one corner by a string, drop a plumb line through point of support and draw a line showing the position of the plumb line. Suspend it from another corner and repeat, the intersection indicates center of gravity

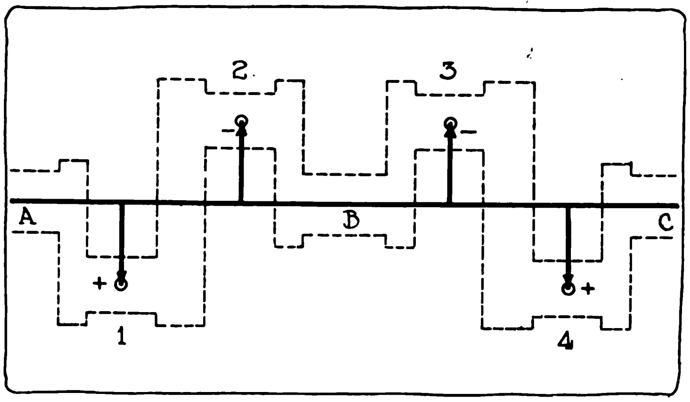

Fig. 3—Diagram showing the points of application of the forces on the crankpins as projected in the horizontal plane

by dimensions, Fig. 1, and that we assume a speed of 2,400 revolutions per minute.

The centrifugal force, F, equals:

$$F = 1.2276\ WRN^2.$$

Where F = centrifugal pull in pounds.
W = weight in pounds.
R = radius in feet.
N = revolution per second.

For big end of rod

$$F = 1.2276 \times 3.75 \times .25 \times 1{,}600 = 1{,}841 \text{ pounds.}$$

For crankpin

$$F = 1.2276 \times 3.5 \times .25 \times 1{,}600 = 1{,}718 \text{ pounds.}$$

For W

$$F = 1.2276 \times 3.75 \times .23 \times 1{,}600 = 1{,}694 \text{ pounds.}$$

Since the center of gravity of the rod big end and that of the crankpin coincide we have a total force of 1,841 + 1,718 = 3,559 pounds acting in a plane 1 1-4 + 1 + 1 1-4 = 3 1-2 inches from the middle of bearing (*a*) and 8 inches from bearing (*b*).

Similarly we have a force of 3,559 pounds acting in a plane 3 1-2 inches from bearing (*b*) and 8 inches from bearing (*a*), but the force due to crankpin No. 1 is in one direction which we shall call positive (+), while the force due to crankpin No. 2 is in the opposite direction which we shall call negative (—). The directions and relative locations of these forces are illustrated diagrammatically in Fig. 3.

The total resultant forces acting upon each of the three bearings due to each of the four crankpins and rod big ends is as follows:

$$\text{On A due to} \left(\begin{array}{l} \text{No. } 1 = +3{,}559 \times \dfrac{8}{11\frac{1}{2}} \\ \text{No. } 2 = -3{,}559 \times \dfrac{3\frac{1}{2}}{11\frac{1}{2}} \end{array} \right)$$

$$= +3{,}559 \times \frac{4\frac{1}{2}}{11\frac{1}{2}} = +1{,}392 \text{ lbs.}$$

$$\text{On B due to} \left[\begin{array}{l} \text{No. } 4 = +3{,}559 \times \dfrac{3\frac{1}{2}}{11\frac{1}{2}} \\ \text{No. } 2 = -3{,}559 \times \dfrac{8}{11\frac{1}{2}} \\ \text{No. } 3 = -3{,}559 \times \dfrac{8}{11\frac{1}{2}} \\ \text{No. } 4 = -3{,}559 \times \dfrac{3\frac{1}{2}}{11\frac{1}{2}} \end{array} \right]$$

$$= -3{,}559 \times \frac{9}{11\frac{1}{2}} = -2{,}784 \text{ lbs.}$$

$$\text{On C due to} \left(\begin{array}{l} \text{No. } 3 = -3{,}559 \times \dfrac{3\frac{1}{2}}{11\frac{1}{2}} \\ \text{No. } 4 = +3{,}559 \times \dfrac{8}{11\frac{1}{2}} \end{array} \right)$$

$$= +3{,}559 \times \frac{4\frac{1}{2}}{11\frac{1}{2}} = +1{,}392 \text{ lbs.}$$

In the same manner the weights W, X, Y and Z distribute their pressure as follows:

$$\text{On A due to} \left(\begin{array}{l} W = +1{,}694 \times \dfrac{9\frac{3}{4}}{11\frac{1}{2}} \\ X = -1{,}694 \times \dfrac{1\frac{3}{4}}{11\frac{1}{2}} \end{array} \right)$$

$$= +1{,}694 \times \frac{8}{11\frac{1}{2}} = +1{,}178 \text{ lbs.}$$

$$\text{On B due to} \left[\begin{array}{l} W = +1{,}694 \times \dfrac{1\frac{3}{4}}{11\frac{1}{2}} \\ X = -1{,}694 \times \dfrac{9\frac{3}{4}}{11\frac{1}{2}} \\ Y = -1{,}694 \times \dfrac{9\frac{3}{4}}{11\frac{1}{2}} \\ Z = +1{,}694 \times \dfrac{1\frac{3}{4}}{11\frac{1}{2}} \end{array} \right]$$

$$= -1{,}694 \times \frac{16}{11\frac{1}{2}} = -2{,}356 \text{ lbs.}$$

$$\text{On C due to} \left(\begin{array}{l} Y = -1{,}694 \times \dfrac{1\frac{3}{4}}{11\frac{1}{2}} \\ Z = +1{,}694 \times \dfrac{9\frac{3}{4}}{11\frac{1}{2}} \end{array} \right)$$

$$= +1{,}694 \times \frac{8}{11\frac{1}{2}} = +1{,}178 \text{ lbs.}$$

The total pressure on the center bearing due to centrifugal force = — 2,784 — 2,356 = — 5,140 pounds.

On end bearings = + 1.394 + 1.178 = + 2,570 pounds.

On connecting-rod bearings = 1,841 pounds.

The pressure on the main bearings may be eliminated by the use of counterweights located opposite the crank cheeks W, X, Y and Z.

The pressure on the connecting-rod bearing may be only slightly reduced since it is controlled by the weight of the big end of the rod, the strength of which must not be sacrificed.

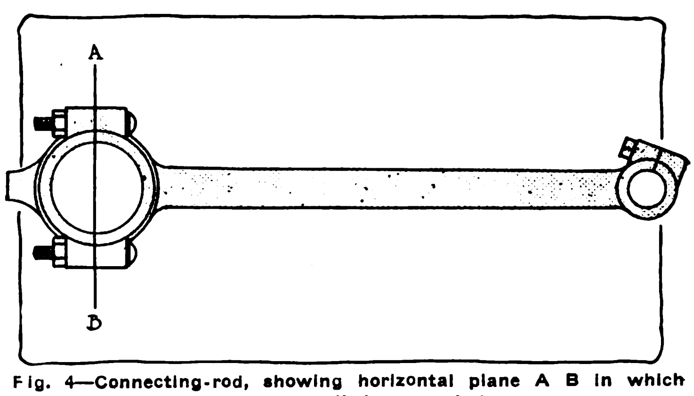

Fig. 4—Connecting-rod, showing horizontal plane A B in which forces are applied to crankpins

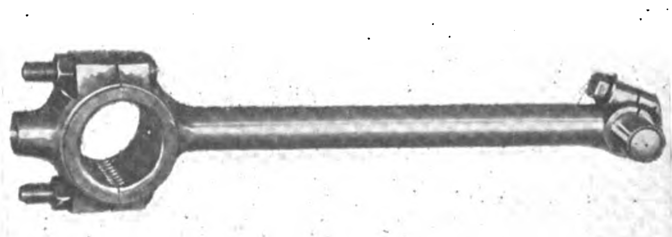

Fig. 5—Tubular form of connecting-rod, showing extension at lower end for balancing

However, at the time of the explosion the pressure on the rod bearing is reversed, thus permitting a renewal of the oil film.

THE SHAPE AND SIZE OF COUNTERWEIGHTS REQUIRED TO ELMINATE PRESSURE ON MAIN BEARINGS IS DETERMINED PARTLY BY THE CLEARANCE SPACE ALLOWED IN THE CRANKCASE.

THE CLOSER (LONGITUDINALLY) THE COUNTERWEIGHT IS TO THE BEARING TO BE PROTECTED AND THE GREATER THE RADIAL DISTANCE FROM ITS CENTER OF GRAVITY TO THE AXIS OF THE SHAFT THE LESS WILL BE THE WEIGHT REQUIRED.

As a rule, it will be found necessary to make the counterweight nearly as large as the space will permit. Fig. 4 shows in section a convenient form of counterweight, the weight of which may be regulated by the thickness. The center of gravity may be found mathematically or experimentally as may also the weight. Suppose it is found possible to locate the center of gravity of the counterweight 3 1-2 inches from the axis of the crank and that the maximum weight possible is 7 pounds and thickness = 1 inch.

$$F = 1.2276 \times 7 \times \frac{3.5}{12} \times 1{,}600 = 4{,}010 \text{ lbs.}$$

The pressure on bearing (*a*) will be:

due to counterweight 1 $= -4{,}010 \times \frac{9\frac{3}{4}}{11\frac{1}{2}}$

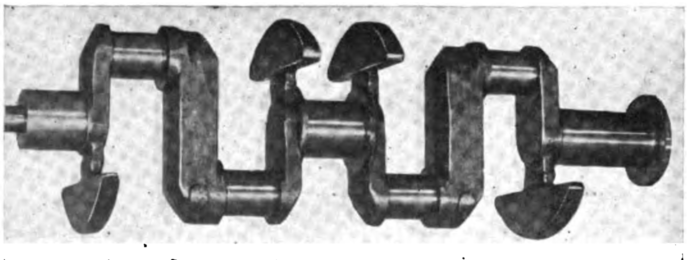

Fig. 6—Counterbalanced crankshaft which is designed to eliminate whipping at peripheral speeds

due to counterweight 2 $= + 4{,}010 \times \frac{1\frac{3}{4}}{11\frac{1}{2}}$

$$= -4{,}010 \times \frac{8}{11\frac{1}{2}} = -2{,}789 \text{ lbs.}$$

This being slightly more than necessary, the thickness may be reduced from 1 inch to:

$$2{,}570 \div 2{,}789 = .921 \text{ or practically } \frac{59}{64} \text{ inch.}$$

—L. J. PETRE, 13,242 Forest Hill road, Cleveland, O.

With a Car at the Front in France

(*Continued from page* 659)

As we approached Paris the control became particularly severe. Down the road the glitter of a bayonet would be seen and the word "Halte" would ring out. It was necessary to pull up sharply, for the sentinels in this part of France are territorials whose guns go off easily. Climbing a winding hill at a rapid clip, I had just made an unsuccessful attempt to avoid running down a cat when I became conscious of a figure dancing a jig in the center of the road ahead of me and pointing a bayonet at the car. It was an inexperienced territorial looking for the most vulnerable part of a car to attack with a bayonet. I relieved him from his embarrassment by pulling up a couple of inches from the end of his steel. Very cautiously he came round to the side of the car and demanded our papers, which were presented and examined in silence.

Barricades on Roads

On the outskirts of Versailles barricades had been put across the road. They consisted of two walls, each one-half the width of the road, placed on opposite halves and about 10 yards apart. It is possible to zigzag through them, but utterly impossible to go by at speed. As no lights are employed, it is necessary to keep a sharp lookout to avoid running into the barricades.

Two days before a group of German spies dressed as English officers had attempted to get into Paris with an automobile at night. They had actually got inside Versailles before their daring attempt was discovered. In consequence of this we were submitted to a searching examination at each post. To add to the difficulties it was discovered that we had been given the wrong password for that night. We were held up at the point of the bayonet while the guard was turned out and officers were brought. Fortunately among the officers there was a personal friend, who understood the mistake, and gave us the correct password, with which we could enter deserted Paris at 2 a. m.

At 8 a. m. that morning a start had to be made for the firing line. The trip was made through the forest of Villers-Cotteret, where a day before the French had destroyed a German motor train of sixteen vehicles. The train was entirely loaded with gasoline and was surprised by a body of French dragoons reconnoitering in the forest. By a well-directed shot the driver of the first truck was brought down. Deprived of its guiding hand, the vehicle zigzagged wildly about the road, causing the followers to collide with it. In the confusion of the attack fire broke out and in a few seconds those sixteen trucks were a mass of twisted iron.

Germans Wreck Cars

Automobile captures are rather rare. Whenever the Germans are hard pressed and have to leave their vehicles they generally find time to wreck them. The method usually adopted is to take off the radiator and throw it in the river if there is one near, or carry it away. The Allies are almost equally careful not to allow their cars to fall into the hands of the enemy; the result is that the country-side is strewn with wrecked cars. When this war is over the work of replacement will be enormous. Such a killing pace has to be maintained and the time allowed for adjustments is so short that even the best of cars must have a shortened life.

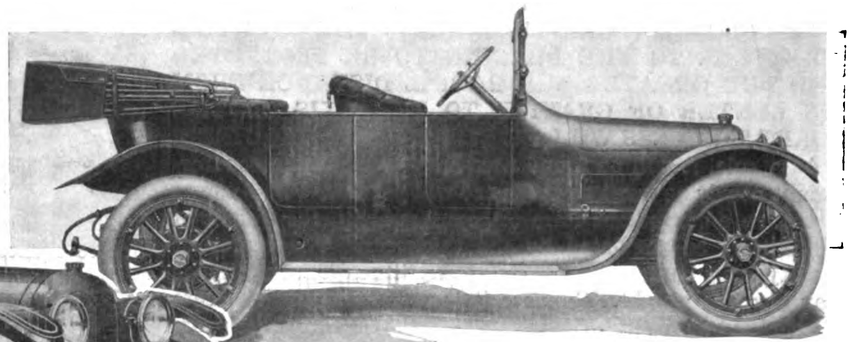
From what I have been able to observe, the Germans are making a greater use of motor guns than are the Allied forces. When the war broke out the English and French had very few armored cars. The Germans, on the other hand, had large numbers in readiness and certainly have used them with effect. With guns mounted on automobiles the Germans are able to keep up a steady fire until the enemy is almost on them and then get away in safety with the guns.

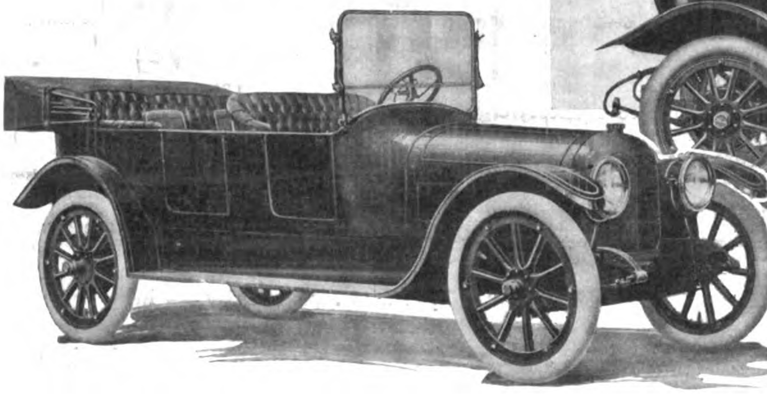
In a certain measure this inferiority of the Allies in the matter of automobile guns has been removed since the war broke out. The French army has obtained from the De Dion Bouton and Schneider factories a special chassis capable of carrying really heavy guns and with such provision that the guns can be fired from the chassis. When the gun goes into action the chassis is stiffened by a series of struts.

Coming through a certain town at midnight I was able to appreciate the important role played by automobiles in moving troops rapidly from place to place. In the wide avenues and public square of this town fully 1,000 touring cars and about 200 motor buses and observation cars were drawn up in orderly lines ready to move a mass of infantry. There was provision for moving 8,000 men at 25 miles an hour.

Apperson Adds New Four and Six

Line Now Comprises Two Fours and Two Sixes





Left—New Apperson 6-45 seven-passenger touring car selling for $1,785. Above—Apperson new 4-40 five-passenger touring car for $1,480

TWO entirely new cars, one a four and the other a six, have been added to the Apperson line for the 1915 season. This brings the number of models marketed by this concern, which is now in its twenty-third year, to four —two fours and two sixes.

The two new cars are similar in design, although the dimensions of the motors and the wheelbases are different. The new four, which is known as model 4-40, is built on a 116-inch wheelbase and has a 4 by 5-inch power plant with L-head block cylinders. The new six is known as model 6-45 and has a 3.5 by 5.125 motor, and also has the cylinders of L-shape in a single casting.

Both these cars incorporate many features of design which have hitherto been unknown to Apperson practice. In the motor castings the core work has been so arranged that the air before reaching the carbureter is drawn through a passage cast in the exhaust manifold, and passes along the heated metal. In the six this heated air scheme has been carried out even more thoroughly than in the four, as in this motor there is no exterior air pipe to the carbureter. In the four the air enters the passage in the exhaust manifold casting and is led through to the other side of the motor, and then by means of a flexible tube, to the carbureter.

Another unique feature that will be seen in the new Apperson is the method of carrying the spark and throttle linkage. As the carbureter is on one side of the engine and the magneto on the other, it is necessary to carry a transverse control rod. This has been neatly taken care of by a tube which passes straight through the motor casting acting as a bearing for this transverse shaft.

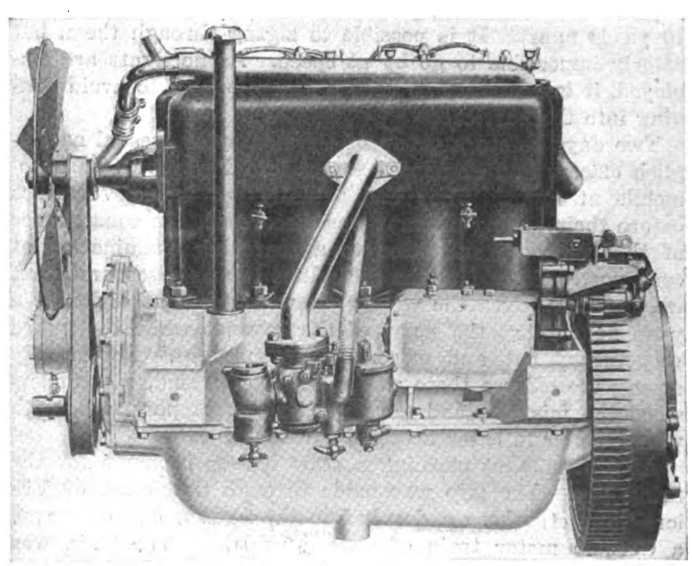
Narrower Turning Radius

While the suspension of the motor is the same as that of previous Appersons in that it is carried rigidly at four points, an alteration has been effected in the narrowing of the main frame, which not only provides a strong motor support with all the advantages of a sub-frame, but also permits of a narrower turning radius in steering the car.

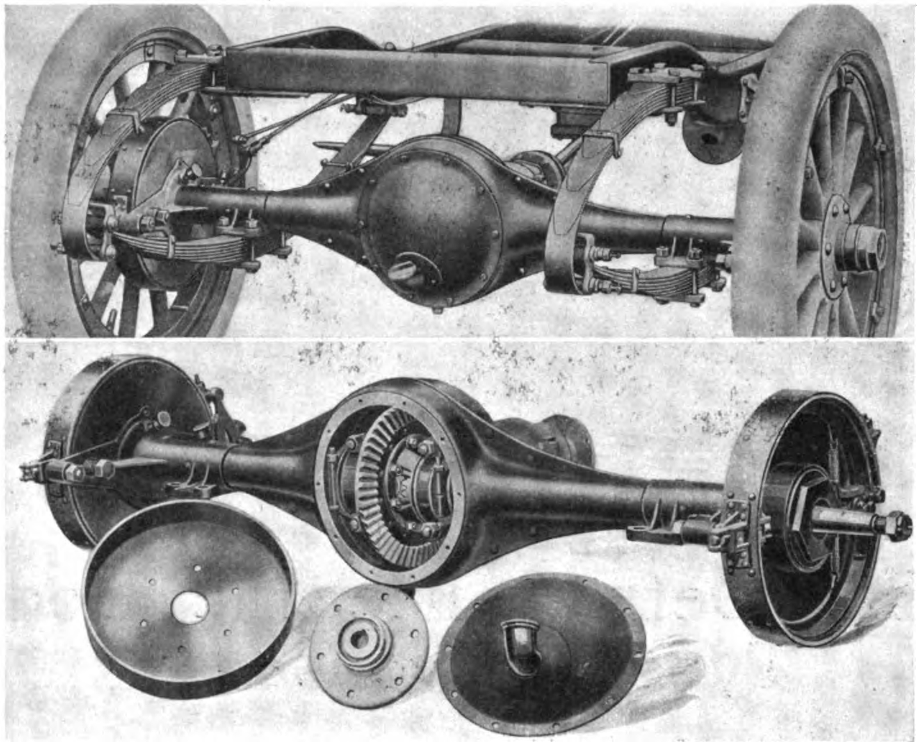
Force-feed lubrication to the main and crank bearings is continued in both the new four and six, but it has been improved in that independent force feed leads are also carried to the bearings of the camshaft.

The water-cooling system on these new Appersons is different from that employed on any other American car. The water is pump-circulated by centrifugal impeller mounted in in a casing forward of the timing gears. It is carried to the top of the water-jacketing instead of to the bottom as is the general practice. The casting which acts as the water outlet on the top of the cylinders is a double one, serving also the purpose of a water feeder. Baffle plates and partitions are so arranged in the cylinder casting that the water passes down on one side of the cylinder, and up on the other, forming a complete circulation. The baffling arrangement in the four differs from that used in the six. In the former the water enters the jacketing space on the left side, and flows downward to the bottom of the jacket and then up on the right side back to the radiator. On the six, the water is led along a space at the tops of the cylinders until it reaches the rear end of the motor, and then passing a horizontal partition, it flows back to the forward end, and then out to the radiator.

Some slight detail changes in the actual construction of the chassis will also be noticed. These are all in the line of lightening and simplifying the car without in any way detracting from its structural strength. The transverse shaft which carries the brake and clutch covers is an example of this. This shaft formerly extended all the way across the frame construction. It is now only one-half its former length, and is supported from the transverse angle bar that



Left side of four-cylinder motor used in Apperson 4-40, showing mounting of Rayfield carbureter and Bijur cranking motor



Upper—Rear construction of new Apperson cars showing small differential housing and underslung rear spring. Lower—Rear axle partially disassembled, showing brake construction

acts as the support for the forward end of the gearbox.

Another factor in the production of the very simple chassis is in the mounting and arrangement of the brake and clutch control members. Practically all of these are assembled directly in the gearbox cover plate. In fact, when the latter is removed, it carries with it the gearshifter lever, emergency brake lever, their bearings and supports and the shifter forks. There is now a flexible coupling between the clutch and gearbox which takes care of any misalignment between these two units. The fulcrum of the emergency brake lever is on a direct level with the floorboards. By this arrangement it is not necessary to cut any slot in the floorboards for the passage of the lever, but merely to have a large enough opening for the insertion of the pivot point.

Drive Taken Through Springs

The rear support of the gearbox is the same as in the past and the drive members from that point back are much the same. Double universal joints, floating axle, and double brakes, one metal-to-metal, and the other fabric, still remain features of Apperson practice. A feature that is an innovation on the new cars is that the drive is taken through the springs. The spring hangers are new, being in the case of the rear support integral with the frame gusset plates, and of strong ribbed section. The front brackets for the rear springs are also new, being of cast steel, and having a double T-section.

This season the Bijur lighting and starting system will be standard equipment. This is a 6-volt double-wire outfit capable, according to the Apperson engineers, of spinning the new four, under ordinary conditions, at a speed of from 90 to 150 revolutions per minute.

The bodies supplied with the new cars have been brought up to date in every particular. On both the 4-40 and 6-45, only the five-passenger touring style is at present supplied. These are painted a special grade of dark blue which the Apperson company has named Elgar blue. They are of modified streamline design with a rounded radiator, having a shield-like dome top, which moulds into the contour of the bonnet. All the control members and the instruments are mounted on a cowl board, which is slightly in-set so as not to interfere with the knee room of the driver. The price of the four with this body, including electric lighting, starting and full equipment, is $1,485, that of the six $1,785.

Power Plants of Similar Design

The power plants on these two new cars are similar in design, although the dimensions are different and there are many other differences in the actual construction. For instance, the piston rings on the four-cylinder model are three in number for each piston, while on the six there are but two. Both pistons, however, are fitted with oil rings. The length of the piston on the four-cylinder is 5.25 inches, while on the six it is 5 inches. The dimensions of the bearings of the crankshafts are also different. On the four-cylinder model, there are three main bearings, the crankshaft is 1.875 inches in diameter for all three bearings, and the lengths of these bearings are respectively 2.5, 3 1-16 and 4 inches for the center, front and rear. On the six, the crankshaft is 2 inches in diameter and is supported on four bearings, the lengths of these being respectively 2 13-16, 2, 2 and 3.25 inches for the front, two centers and rear. Connecting-rod bearings on the six are 2 inches in diameter and 2 inches in length.

The valve action on both models is inclosed by cover plates and is on the right side. The Rayfield carbureter is on the left, and the air intake is led from the opposite side of the motor as previously described. Carbureters are of different sizes, that on the four being a 1 inch, and on the six a 1.25 inch.

An Eisemann magneto forms the sole source of ignition current on both the four and six.

No change has been made in the contracting band clutch which has formed a part of Apperson construction for several years. The component parts of this clutch comprise principally a band and flanged drum. The band is contracted upon the surface of the drum by linkage somewhat similar to that used in operating a contracting brake. Directly behind the drum there is the flexible coupling and then the three-speed gearset which also has been unaltered for this season.

Small Differential Housing

There are two universal joints in the drive and the torque is taken through the rear spring which is underslung on the two new models. The construction of the rear axle is worthy of attention in that the differential and drive pinion have been kept in an exceedingly small housing 6-16-inch thick.

The bearing equipment on both new cars is similar. Timken rollers are used for the pinion shaft and outer end of the axle, while Hyatt's are used for the differential in connection with a ball thrust.

Pressed steel has been used to advantage in many of the small fittings about the car, for instance, in the step hangers, rear tire carriers, and so forth, besides the axle housing and drums. Sheet metal stampings are used to support the muffler instead of the malleable brackets employed in former models. Wood wheels are used as standard on both the new cars, the tire sizes on each being 34 by 4 inches.

Left drive and center control is used on all Apperson cars.

Plan view of chassis used in new Detroit electric. Note controller in housing ahead of motor

Six Detroit Electric Body Types—Two Chassis

All Models Worm Driven Except One

WITH the manufacturing department of the Anderson Electric Car Co., Detroit, maker of the Detroit electrics, so situated that it will be possible to begin shipment of the 1915 models several months earlier than ever before, the concern is enabled to make an announcement of the details of these new cars at this time. No radical changes are made in the principles involved in the construction of 1915 cars as compared with the 1914 output, indicating that the Anderson company feels that it has arrived at a standard construction of approved excellence.

Five Worm-Drive Models

The 1915 Detroit electric offering will be six body types, five of which are mounted on a chassis of 100-inch wheelbase, while only one of them, a four-passenger rear drive brougham, is fitted to a chassis with 94-inch wheelbase. All of the models on the longer wheelbase have worm drive with the worm underneath the wheel and their battery is slightly larger capacity than that of the other model, which is fitted with a bevel gear rear axle. Wood wheels, with either Goodrich Silvertown cord or Motz cushion tires, or wire wheels, with Silvertown cord tires, are optional.

Prices are practically the same as they were, although due to greater refinement and finish they are in some cases slightly higher. Model 50 cabriolet is priced at $2,650 with lead battery and $3,530 with Edison battery; model 51, four-passenger brougham, at $2,850 with lead and $3,730 with Edison; Model 52, duplex-drive, five-passenger brougham, at $3,000 witih lead and $3,880 with Edison; model 53, forward drive, five-passenger brougham, at $2,950 with lead and $3,830 with Edison; model 54, rear drive five-passenger brougham, at $2,950 with lead and $3,830 with Edison; and model 55, rear drive four-passenger brougham with lead battery at $2,600. The last-named, model 55, is the 94-inch wheelbase car and corresponds to last season's model 43 selling at $2,550. Model 53 corresponds to the $2,850 car of 1914, while the duplex drive model 52 is the same in price as the one it succeeds of 1914, and so on.

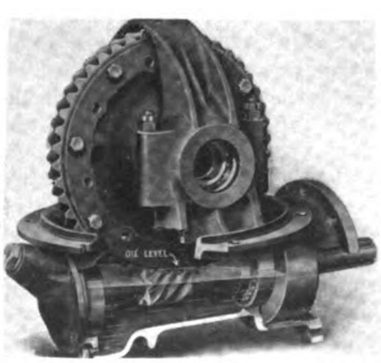
Battery Capacity Increased

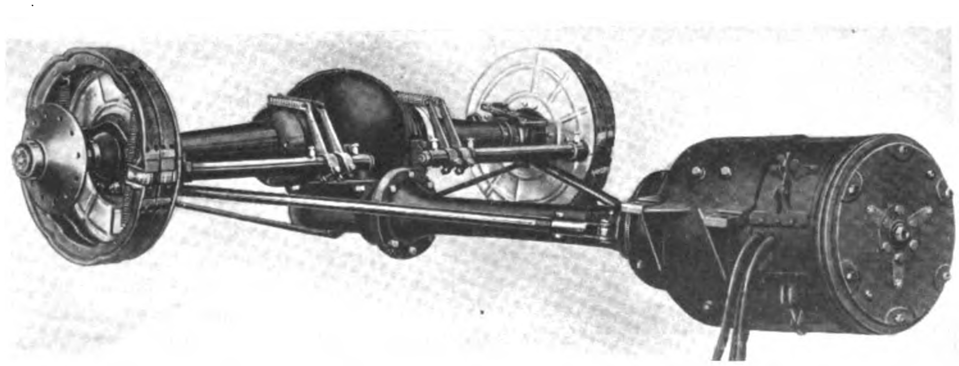
Battery capacity has been somewhat increased, and though the number of cells is the same as last year, the number of plates per cell has been increased from 13 to 15, this referring to the lead batteries. That is, the 100-inch wheelbase cars have 42 cells of 15 plate type instead of 13 plate, while the 94-inch has 40 cells, also 15 instead of 13 plate.

A new feature of importance is the metal compartment ahead of the motor and accessible through a trap door in the floor, in which is mounted the controller mechanism, brake on the head of the motor, the Klaxet horn, which replaces a bell as a warning signal, the ammeter shunt and the throw-over switch used to change the lighting connections from one-half of the battery to the other. The trap door is fastened in and prevented from rattling by rubber rollers. For additional protection, the controller has an extra cover of its own which can be removed by loosening two clips. To remove the controller from the car it is only necessary to disconnect the cables and remove three screws, when the controller can be lifted bodily through the trap door.

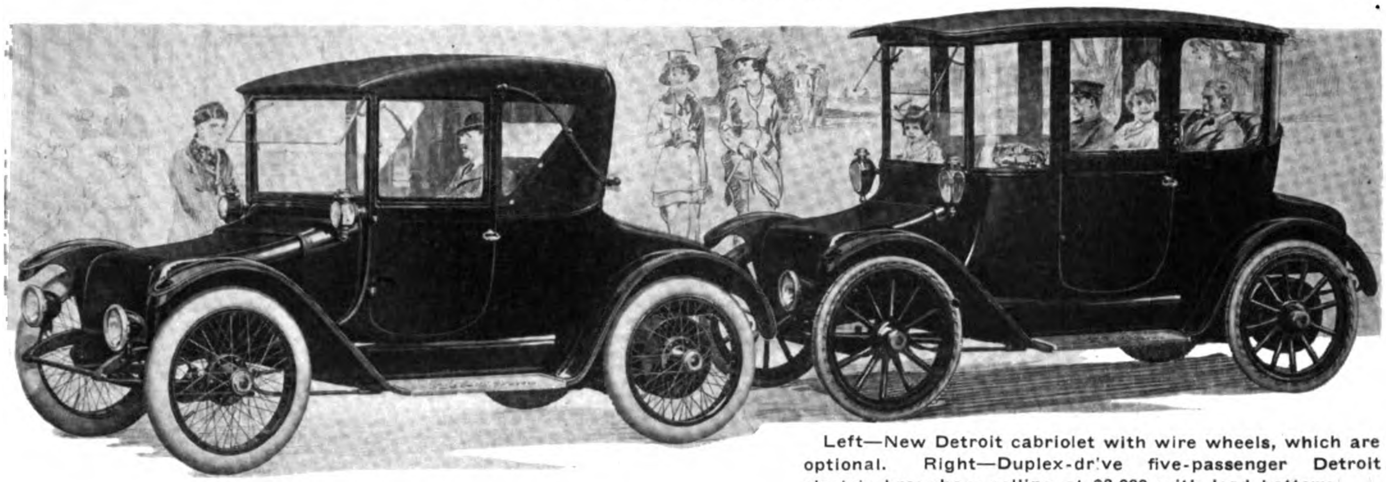
Due to this new controller location and also to a new scheme of wiring whereby all wires are led to a terminal board provided under the left end of the rear seat and all wires leading up from the chassis and down from the body are connected to numbered positions on this terminal board, it is a very easy matter to take the body from the chassis without in any way disturbing the wiring.

Detroit electric bodies, which are constructed entirely in the





Left—Lanchester-type worm gear used in the Detroit electric. The worm runs in a bath of oil. Right—Drive unit, showing underneath worm and inclosed propeller shaft



Left—New Detroit cabriolet with wire wheels, which are optional. Right—Duplex-dr've five-passenger Detroit electric brougham selling at $3,000 with lead battery

company's shops, are examples of the highest art in coach work and are even more refined than in the past. The door windows are sashless and fitted with a new type of window lift to replace the hand lifting by means of straps. It is merely necessary to turn a small nickel-plated handle to raise or lower the glass the desired amount.

As an illustration of the refinement to which the body construction has been carried, aluminum drip moldings have been placed over the doors to prevent water from dripping upon those entering or leaving the car on a wet day. Door panels are of solid sheet aluminum with moldings pressed in, thus entirely eliminating the separate moldings formerly used. The window sashes are all metal covered, eliminating the possibility of checking or warping.

Steering continues to be by means of a horizontal lever mounted parallel with the control lever, the latter being operated by the left hand and when advanced accomplishes the forward or reverse movement of the car. In reversing, the control lever is first brought to neutral position, raised slightly until it comes in contact with a stop, and then advanced in the usual way. When brought back to neutral again after reversing, it automatically drops into normal position for running forward, making it impossible to start the car backward when it is desired to go ahead after having reversed the car.

Interlocking Emergency Cut-Out

There are two brake pedals, each of which operates independently a pair of internal expanding brakes on the rear hubs. Between the brake pedals is a third small pedal which operates the emergency cutout switch and sets the brake ratchet. A pressure of the foot on the three pedals at once cuts off the power, regardless of the position of the control lever and locks both hub brakes. It is then impossible to release the brakes until the control lever is returned to its extreme backward position. A Yale locking device is also provided.

In the duplex control models, the interlocking cut-out feature also prevents starting the car from either driving position unless the pedals are in position to operate from that seat. In these models providing drive from either seat, there are two sets of steering and control levers and two sets of brakes. The operation of shifting pedals from one driving position to the other has been simplified. This is accomplished by pushing forward the small lever at the side of the front steering mast head, which releases the brake pedals so that they can be pushed with the foot flush with the toeboard. This automatically locks the pedals which have been pushed down and raises the other set of pedals to the operating position.

As heretofore the battery is carried in front and rear compartments and the jars are of the high ribbed type, making it unnecessary to wash the plates. Mileages of from 50 to 85 miles per charge are obtained. There are in the 100-inch wheelbase models eight trays placed lengthwise of the car, four under the front hood and four under the rear.

The drive system is practically the same as it was, the motor, torsion tube and rear axle being in unit. The motor is series wound and is said to have high torque characteristics and very low internal resistance. It is held on the under side of the supporting rails by large steel bolts so that it may be released and easily lowered to the ground.

Lanchester Type Worm Used

The Lanchester type of worm gear which is used on all the models excepting the one mentioned is of the type in which the worm is below the wheel and runs continually in a bath of oil. Axles are floating, while the housings have been somewhat re-designed in order to give them greater strength while reducing the weight.

The brakes used have been improved by the addition to the drums of stiffening flanges. Both brakes are internal expanding and measure 16 inches in diameter by 1 1-4 inch width.

Advocates Engines Running Over 1,500 R.P.M.

EDITOR THE AUTOMOBILE:—*I have just read the article by a British writer, on the slow and high-speed engine, published in your September* 10 *number, page* 490, *but cannot agree with his views.*

It is true, of course, that the measure of efficiency in an engine which has to propel itself, as is the case with an automobile or aeroplane engine, is the ratio of its power to weight, but it hardly seems credible that the author can believe that the highest results can be obtained with an engine running 1,500 *revolutions per minute; for if he but look at any of our recent high-speed engines he will receive a surprise. Take for example the Deltal engine described some time ago in your columns. This engine develops about* 90 *horsepower at* 3,000 *revolutions per minute and weighs* 570 *pounds with carbureter and magneto. This is* 1 *horsepower for every* 6 1-3 *pounds.*

I would like very much to see an engine of any piston displacement whatever which can produce this ratio of power to weight at 1,500 *revolutions per minute.*

Nor is the above engine of the double-valve, over-head type which has shown even better results in racing. It is merely a large-valve, L-head type of good design.

As to aeroplane engines running at about 1,500 *revolutions per minute, this is because these engines are run most of the time at nearly their maximum power and it is not advisable to run an engine where such extreme reliability is required at* 3,000 *revolutions per minute even though modern engines are very reliable at that speed. In an automobile, however, it is desirable to have an engine capable of extreme speed and power when such may be needed, even though the engine is not regularly run at such extreme speeds. Also, the modern, high-speed engine, which gains its power by large valves and not by extreme valve timing, will not show much if any difference in power compared with the low speed type at* 1,000 *revolutions per minute.*

Southport, Conn. EDWARD G. INGRAM.

Reader Gives Views on Modern Gas Engine Design

EDITOR THE AUTOMOBILE:—This subject should interest those contemplating a change in their power plant and will aid those who attempt to solve the problem of making a purchase by a study of numerous designs as displayed in the many trade papers.

I note that there are something like 200 different motor designs with no two alike. There is also a total lack of similarity in power rating for a given bore and stroke. There are high-speed, medium-speed, and low-speed, sometimes called high-duty or heavy duty for a given horsepower. The price is generally high and the weight is generally heavy. The term is a very vague and misleading one and any prospective buyer to insist on such an installation for a speed boat would be considered joking. High whether used in connection with speed or power means the same. Consider an engine with, say, three cylinders 5 by 5, at 800 revolutions per minute. It develops 25 horsepower and weighs 500 pounds. It may be a heavy engine compared with another of the same power or where three cylinders 4 by 4 at 1,200 to 1,300 revolutions per minute develops 28 horsepower. In the latter case we have high power with light weight and this is a most desirable power plant for a boat outside of a heavy fishing boat with full lines and where weight is not a detriment.

There is also another perplexing consideration and the more the average novice studies catalogues and sectional cuts the more confused he gets and the more convinced is he that there are no fixed laws governing engine design as applied to the two-cycle marine engine at least. The most amusing part of it is how one concern will claim a decided advantage for a feature another will condemn. The detachable cylinder head feature is one so amusing to me that I fail to see how some concerns can muster sufficient nerve to blow about a feature others avoid and in doing so resort to all kinds of intricate castings besides adding to the cost of machining the bore with a closed end. This is true in the highly developed standard automobile designs. There are, however, some exceptions. For structural reasons a solid head would be impracticable, as in the silent Knight or engines with valves in the head; and some of those prefer to use valve cages rather than add a needless joint at a point where the jacket is most essential, when otherwise surplus metal to retain studs would restrict the circulation besides tending to distort the bore by unequal expansion.

Personally I prefer to increase the volume of water space at the head and reduce it to the practical limit at the lower end, this reduces the tendency to form a rib where the jacket stops on the bore and aids circulation by convection.

Carburetion is getting to be a problem due to low-grade gasoline and while the automobile engineer has ideal conditions due to an inclosed engine kept warm by its own heat no car is considered up to date that does not make provision to heat the charge leaving the carbureter by some means and all modern carbureters are provided with an attachment to heat the primary air by means of a sleeve fastened to the exhaust pipe connected by a tube or flexible pipe and yet there is a painful absence of any marine engine so fitted, to combine the inlet and exhaust pipe does seem the logical method of retaining a mixture after it leaves the carbureter were it not for the fact that the exhaust pipe is not the same temperature at any point compared with that of some other. If we take a three-cylinder, the charge entering the cylinder at the end (outlet) of the exhaust pipe comes in contact with the total heat of three cylinders, the charge entering at the middle cylinder comes in contact with that of two units, while that entering the other has a heat contact of the cylinder it enters only. This is a condition tending to graduate the density of the mixture into lean, medium and rich, which in turn causes no two cylinders to be of the same power and may account for backfiring in one or the other according to the adjustments used, or if a change is made to eliminate backfiring the over-rich cylinder will four-cycle, which is equally bad and wasteful. I would recommend that sufficient heat be absorbed by air entering the carbureter to make and retain a uniform charge of such a nature that condensation is prevented.

The dangers arising from the backfiring bug-a-boo while real are simply due to a lack of sufficient fuel rather than a defect in design. If we trace the cause of the backfiring we will find regulation will stop it. This may be done by enriching the charge or by the more logical method of air scavenging the cylinder.

Cleveland, O. JAMES MCINTOSH.

Description of Delco Circuit-Breaker

Editor THE AUTOMOBILE:—Will you please explain what the circuit breaker on the Delco system is for and how it operates?

Chicago, Ill. H. M. W.

—The circuit breaker used in the Delco system is for the purpose of interrupting the circuit between the source of current supply and the lamps, etc., when a wire becomes grounded. The source is the storage battery or the generator, depending on which happens to be furnishing the current.

It consists of an electro magnet with a single winding and it opens and closes the circuit leading to the lamps, horn and ignition through contacts A, Fig. 1.

When there is a ground or short circuit in one of the wires, it causes an excessive flow of current which goes through the winding of the circuit-breaking relay. The increased current produces a magnetic pull between the pole piece B and the armature C, which in turn causes the extension D of the armature to give a hammer blow effect on the point E and cuts off the current supply. The opening of the contact kills the magnetic pull between the pole piece B and the armature C and the contacts close again, but are opened as soon as contact is made. The relay will continue to vibrate until the ground or short circuit is removed. The spring F is for the purpose of holding the armature away from the pole piece.

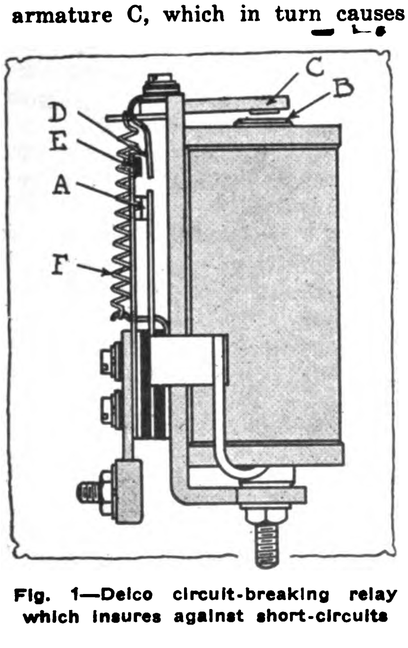

Fig. 1—Delco circuit-breaking relay which insures against short-circuits

A current of approximately 25 amperes is required to trip the circuit-breaking relay, but after it is in operation a current of approximately 5 amperes will cause it to continue vibrating until the ground or short circuit is removed.

The function of the relay is the same as that of a fuse except that it eliminates the necessity of replacing fuses or fuse blocks.

How to Wire Master Vibrator

Editor THE AUTOMOBILE:—Will you please give me an illustration showing how to connect a master vibrator to a four-way coil on a 1914 Ford?

Ilion, N. Y. R. B. FISK.

—A typical wiring diagram is that of the K-W Master

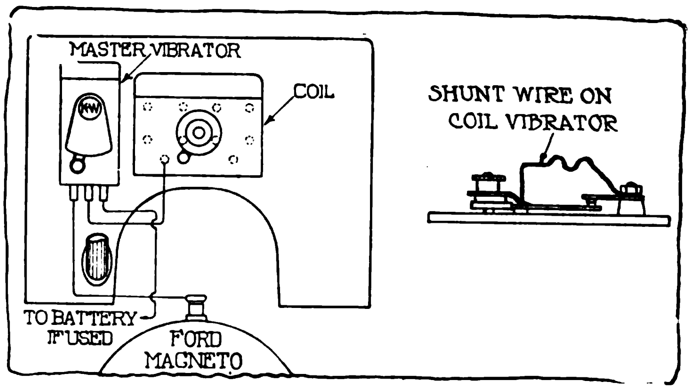

Fig. 2—Left—Diagram showing master vibrator attached to Ford. Right—Shunt wire for short-circuiting individual vibrators

vibrator shown in Fig. 2. The wiring diagram is easily understood. The master vibrator is mounted in a convenient place on the dash, either at one side of the coil or directly on it. The usual place is just above the steering post on the left side of the dash, as shown in the diagram. The switch of the vibrator is used to start and stop the motor, and the switch on the coil is thrown over on the lead that connects to the master vibrator. None of the timer leads or spark plug wires are disturbed.

It is important that the vibrators on the coil be short-circuited, either by screwing them down tight or by bridging them with copper wires, the latter method is better. This is done by attaching a small copper wire, as shown in the corner of the illustration.

How Rotary Valve Is Timed

Editor THE AUTOMOBILE:—In your issue of September 24, page 581, Mr. Furst asks about timing a rotary valve engine. Your reply does not coincide with my experience with those engines, so I take the liberty to reply. A rotary valve which turns at half crank speed is a very fast valve and so opens quicker than the usual poppet valve, and on this account does not need to be opened so early. Of course, much may depend on the design of the valve, but such engines as I have built with rotary valves had this advantage. One of them was exhibited at the New York show in 1907. A recent table published in the *Motor Age* gives the timing of sixty engines and the average, as I remember it, is about as follows: Exhaust opens 45 degrees before center and closes 8 after, followed at once by the inlet opening. The time of closing of the inlet is not a matter of valve but of pipe. If the inlet pipe is long, the valve should remain open long, because the gases once started in the pipe will continue to ram in for an appreciable time. With the above timings Mr. Furst will get good results and high speeds if his valve is properly proportioned. The rotary valve gives not only

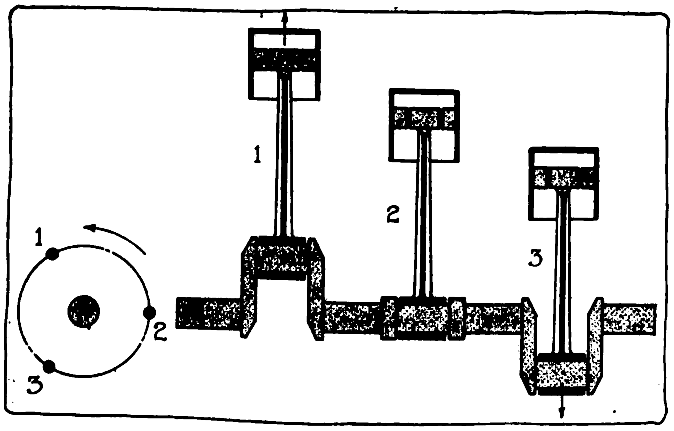

Fig. 3—Diagram showing inertia forces tending to rock a three-cylinder motor

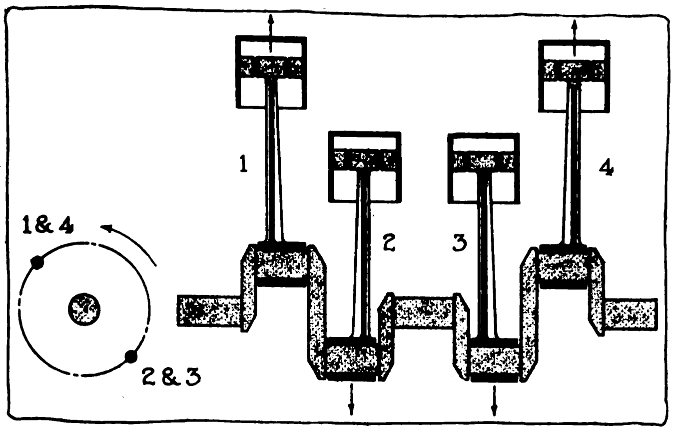

Fig. 4—Diagram showing that in the four-cylinder motor the inertia forces are balanced and there is no tendency to rock the motor

a quick opening but the passage is nearly straight and this lets the gases pass freely and fast.

Philadelphia, Pa. CHAS. E. DURYEA.

Why Not a V Six-Cylinder Motor?

Editor THE AUTOMOBILE:—1—Why was a three-cylinder, four-cycle engine never marketed in an automobile?

2—Would it be practicable to build a six-cylinder engine V shape such as the new Cadillac, but with a three throw crankshaft? If not, what would be the disadvantages?

3—What is the object of automobile manufacturers putting out their new models in Midsummer and Fall instead of Spring?

The farmer is a big factor in buying automobiles today and he would rather buy in the Spring than Fall because he gets little use of a machine in Winter. A new machine bought in the Fall would stand unused nearly all Winter and when Spring comes he hesitates on buying because he knows that there will be new models out in a few months. The early Spring is the time most people get the automobile fever worst.

E. St. Louis, Ill. A SUBSCRIBER.

—1—The objection to the three-cylinder motor is that it is subject to rocking in a longitudinal direction due to the unbalanced moments produced by the inertia forces incident to the reciprocation of the pistons and connecting-rods. Also, while the power impulses may be evenly spaced, they do not occur with sufficient frequency. It has generally been conceded that four cylinders is the minimum.

In understanding the lack of balance in the three, consider first of all the inertia force produced by a single piston and connecting-rod. When these masses are increasing speed, there is a reaction on the motor in the opposite direction to the motion and when they are decreasing speed, there is a reaction in the same direction.

For example when the piston is starting from top dead center its acceleration produces an upward pull, while when it is slowing down, as it nears lower dead center, a downward pressure is exerted. On the up-stroke, the acceleration of the piston causes a downward reaction on the motor and when it slows down near the end of the stroke an upward force is created.

Therefore when the piston is above mid-position the pull is upward and when below, downward. With number two piston and connecting-rod half through the stroke, number one is just beginning and number three is ending the down stroke. There is an upward pull on number one, zero pull on number two and a downward pull on number three, as shown in Fig. 3. One-half revolution later these forces are reversed and the tendency is to rock the motor in the opposite direction.

In the four, all-in-line six and V-type eight this tendency to rock is not present because the moments are balanced. This is shown by Fig. 4. In this motor, which is typical of all four-cylinder designs, the reciprocating parts are symmetrically arranged. When the piston in number one cylinder moves down, so does that of number four. Likewise, when number three piston goes up, number two does also. Therefore, if there is an upward inertia force due to number one there is an equal upward force due to number four. Also, the downward force of two is matched by that of three. The result is that no rocking can take place.

2—The same lack of balance in the three is also present in the six-cylinder V-type, which is merely two sets of three with a 90-degree interval between them. The six also has the disadvantage that the explosions are unequally spaced. With the crank throws 120 degrees apart and two connecting-rods attached to each throw, the explosion will occur alternately at 90-degree and 150-degree intervals.

One advantage of this type of motor, however, would be a shorter overall length and a shorter crankshaft, and camshaft, but the cam followers would be more complicated.

3—There are several good reasons for this practice. Manufacturers from year to year have brought their models out earlier in order to be the first in the field and get the lion's share of the business. Also, when Midsummer comes a man that is in the market for a car hesitates to buy one of this season's models because the year is half over; he would rather wait and get a machine built for next year's trade. If some of these new models are available in the Fall he will buy, but if not, he will wait until Spring. Thus, the Fall is converted into a good selling season. In addition, closed cars are now used more than ever, with the result that there are a great many sold in the Fall. People buying these cars, however, would probably defer purchase in a great many cases, if they could not obtain new models.

Thus it is seen that instead of the selling season being confined to the Spring months it is now spread fairly well throughout the year, by this policy. This facilitates production and allows the manufacturer to operate at a more nearly constant rate, instead of rushing manufacture in the Winter and Spring and closing down in the Summer, as used to be the case.

Circulation Stopped—Motor Heats

Editor THE AUTOMOBILE:—1—I have a model 10 Buick and am experiencing quite a little trouble with the cooling system. After running for a few minutes the water boils away rapidly. The radiator inlet pipe becomes very hot as does the extreme top of the radiator. The rest of the radiator remains cold and the outlet to the pump, as well as the pump remains cold. I have had the pump apart and it seems in good order. The radiator drains out all right.

2—When running on high the car occasionally indulges in back jumping and I suspect the clutch or the planetary transmission. It seems to occur most frequently when the throttle has just been opened a slight amount. It has a Schebler carbureter, well-adjusted and the newly fitted Bosch, independent magneto gives perfect ignition.

Hollis, L. I. R. M. DE VIGNIA.

—1—Either your pump is not working or the cooling system is stopped up. The fact that the pipe running to the radiator is hot and the lower part of the radiator and the piping to the pump is cold, shows that there is no circulation. Look for loose pieces of hose or dirt in the piping; see that the radiator is clean and examine the pump once more.

2—Due to wear in the bushings in the interior of the mechanism, the three fingers that engage the clutch are now too long and should be shortened by 1-8 inch by bending them that amount. Then adjust the clutch by the turnbuckle under the floor boards. First pull the hand lever back until it clicks, there being a notch with which it registers at this point. Then tighten the turnbuckle until the clutch just begins to take hold.

Increase of Tire Pressure with Heat

Editor THE AUTOMOBILE:—1—Kindly forward to me figures regarding the increase of tire pressure per degree of heat.

San Diego, Cal. H. F. WHITE.

—The increase in pressure for a given rise in temperature can be calculated by the formula:

$$P = \frac{P_1\,(459 + T)}{459 + T_1}$$

Where P_1 = the initial pressure
T_1 = the initial temperature
P = the final pressure
T = the final temperature

P and P_1 refer to the absolute pressure—which is merely the sum of the gauge pressure plus atmosphere, or 14.7 pounds.

If the pressure to which the tire is inflated is 60 pounds and the temperature is 60 degrees then if the temperature should rise to 100 degrees, the new pressure may be calculated by substituting in this formula.

$$P = \frac{60\,(459 + 100)}{459 + 60} = 64.7$$

This represents an increase of 4.7 pounds..

Why Advance Spark Means Economy

Editor THE AUTOMOBILE:—1—Please publish in your paper where the Rayfield cyclecar is made?

2—Why does a car run on less gasoline with the spark advanced.

3—What is the advantage of a spark lever?

Marathon, Iowa. O. A. SMITH.

—1—Rayfield Motor Co., Fisher Building, Chicago, Ill.

2—This is only partly true. There is a limit to the amount the spark can be advanced to improve the economy of the motor. The spark lever should be set so that the greatest power is obtained from the charge. This means that it should merely be advanced to this point. Further movement will cause a decrease in economy. Under a given set of operating conditions the economy is greatest when the motor is operating most efficiently.

Figs. 5, 6 and 7 show three indicator cards, the one at the top showing the effect of very early ignition, the middle one, point of best ignition, and the lower one too late position of the spark. The horizontal distance represents the piston stroke to a certain scale and the vertical distances the pressures in the cylinder at various piston positions. The cross indicates the position of the spark in each case.

It will be noted that the center diagram has the largest area and, as the area is proportional to the power developed, it will be seen that this diagram indicates the greatest power development, or, under a given set of conditions, this position of the spark is the best for economy.

The spark occurs just before the piston reaches the top of the stroke, combustion takes place almost immediately and the pressure rise is indicated by a line that is almost vertical. About the time the pressure has become a maximum, the piston has started out on the power stroke and expansion begins.

With the spark advanced too far, as shown in the upper diagram, the area is reduced. The spark in this case occurs considerably before the piston has reached the top of the stroke, with the result that the explosion line is farther to the left. Nor is it quite straight because the piston is moving fast enough at this point so that it moves an appreciable distance while combustion takes place. Since the pressure rise is probably completed before the piston gets to top dead center. the gas is slightly compressed during the completion of the up-stroke. This may form a slight loop at the apex, as shown.

When the spark is retarded, the piston has already started on the expansion stroke before the ignition takes place. This causes the compression line to double back on itself until the point of ignition is reached when there is a rapid rise of pressure. The top of the card is rounded off, however, due to the acceleration of the piston.

3—The spark lever is for the purpose of enabling the operator to set the time of ignition at will to give best economy and power.

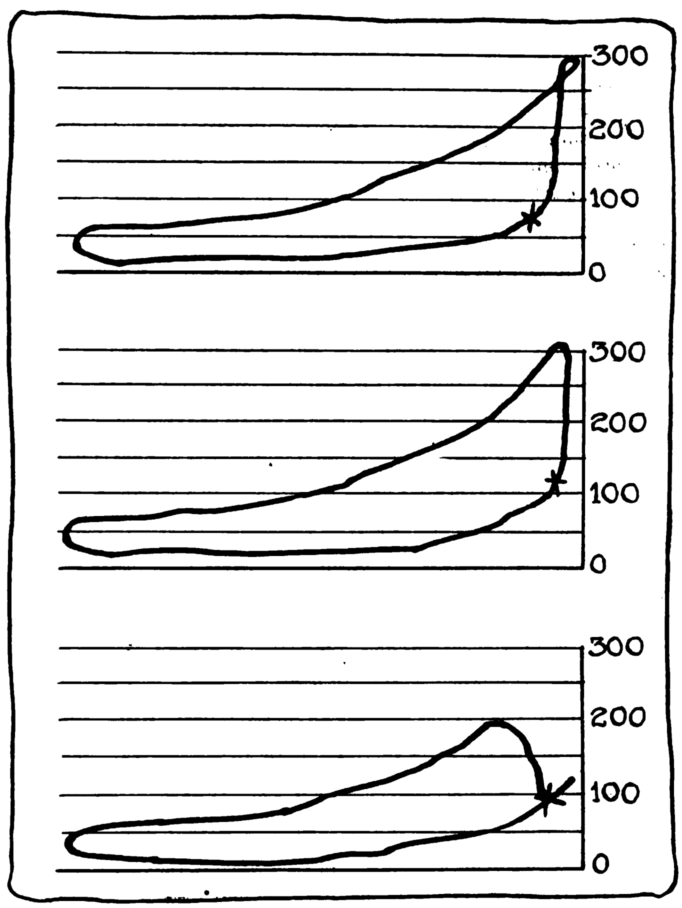

Fig. 5—Upper—Indicator card showing spark advanced too far and consequent reduction in card area

Fig. 6—Middle—Spark properly timed and occurring slightly before dead center. This position gives a maximum area

Fig. 7—Lower—Spark very late. Showing the reduced area and consequent loss of power

G. B. & S. Small Car Unit Power Plant

Weighs 392 Pounds—Easily Installed—Bore 3¼, Stroke 4¼—Detachable Cylinder Heads

ON October 1 the Golden, Belknap & Swartz Co., Detroit, starts production of a new powerplant adaptable to small-car installations. This is called model D and its total weight with gearset, clutch, magneto, motor-generator and carbureter is 392 pounds.

Like previous designs of this make, model D is a unit power plant type arranged for three-point suspension. The gearset bolts to the flywheel housing. The rear motor support with an arm extending for attachment to each side member of the frame is interposed between the flywheel and gearset housings as in former G. B. & S. practice. A special point is made of the simplicity of the application of the motor to any small chassis. It requires only the drilling of one hole through each side of the rear motor support and the insertion of two bolts when the motor is swung in the car frame ready to attach the drive shaft, the front end of the motor fastening with two bolts to a front cross-member of the frame.

The motor, 3 1-4 by 4 1-4 inches, has the cylinders cast in block with valves on the left. The horsepower rating is 17 at 1,000 r.p.m. with 141 cubic inches piston displacement.

Detachable Cylinder Heads New

New to G. B. & S. construction is the detachable cylinder head which is in the form of a single plate securely held in place by steel bolts and exposing all valve pockets, valves, piston heads and cylinders when removed.

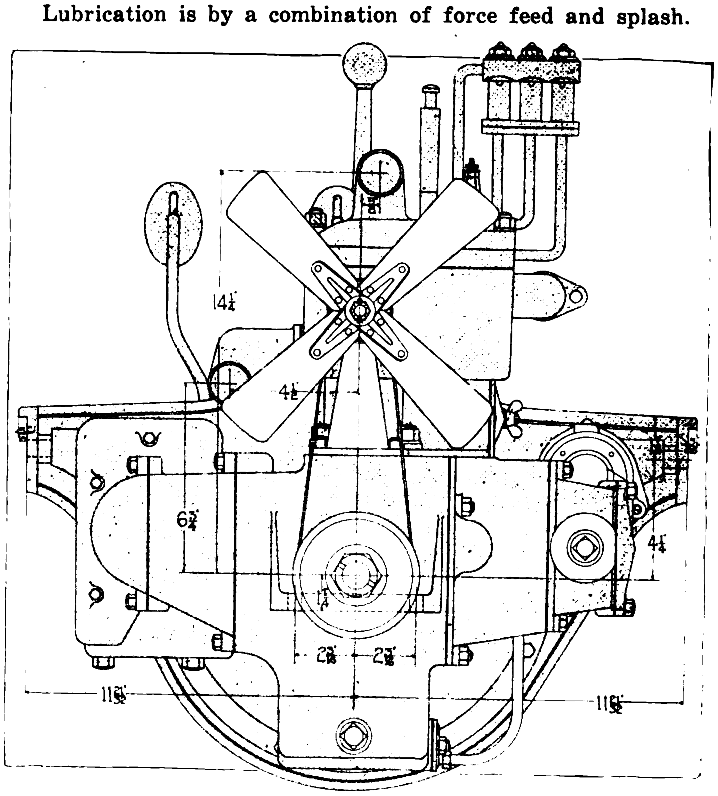
Valves are completely inclosed by a plate readily removed by unscrewing two wing nuts. The valves have cast-iron heads with steel stems. The crankshaft has three large main bearings of nickel motor babbitt.

Silent-Chain Drive

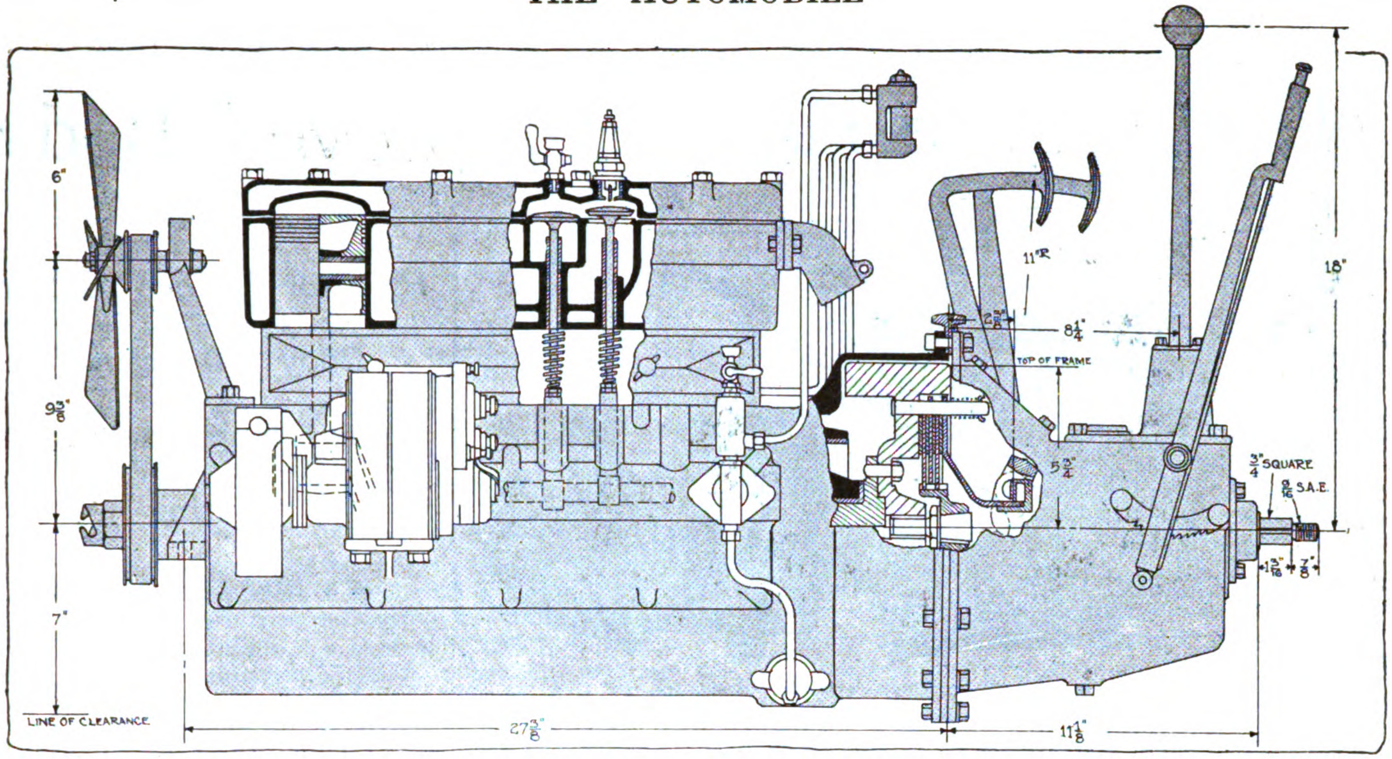
A noteworthy feature is the use of silent-chain drive for the camshaft, magneto shaft and generator shaft. These run in a bath of oil, being completely housed at the front of the motor, and may be adjusted by the insertion of shims of varying thicknesses between that portion of the housing carrying the magneto or generator shaft sprocket and the main housing, this serving to slightly increase or diminish the distance between chain centers. These special shims are furnished by the manufacturer.

The motor is arranged for thermo-syphon cooling with large water connections.

Lubrication is by a combination of force feed and splash.



Front view of motor with the principal dimensions given



Left side of motor partly sectioned and with the principal dimensions given. The overall length is about 44 inches

The motor is equipped with a force-feed oiler, operating from No. 4 exhaust cam. The oil is forced from the oil reservoir at the bottom of the crankcase to the three-feed dash dial, and thence through three pipes leading to the three main bearings. An oil level is maintained in the crankcase from which connecting-rod bearings and pistons are lubricated by the splash from the dipping of the connecting-rod ends.

Motor-Generator System Used

The magneto is carried on the left and symmetry and balance of accessories are obtained by placing the generator and starter on the right. The motor-generator which has been used extensively on this motor is of Apple make, but any one of the well-known makes may be fitted equally well in which the combination of motor and generator is made applicable. The ratio between generator and crankshaft is 2.5 to 1, so that either when cranking or when being driven for generation of current the unit travels 2.5 times as fast as the motor.

Fitted to the motor is a three-speed selective gearset. The power comes to it through a four-plate disk clutch, two of the plates steel and two faced with asbestos woven wire. Pedals and center control levers are a part of the assembly as furnished.

The principal dimensions of the power plant are:

Crankshaft front bearing—1 1-2 by 3 1-2 inches.

Crankshaft center bearing—1 5-8 by 2 1-4 inches.

Crankshaft rear bearing—1 5-8 by 4 inches.

Connecting-rod bearings—1 1-2 by 2 inches.

Flywheel diameter—11 3-4 inches.

Flywheel width—3 13-16 inches.

Crankcase bell housing diameter—12 by 14 inches.

Overall length of power plant from face of fan to end of drive shaft—44 inches.

Distance from center of holes of front support to center of holes in rear support—37 3-8 inches.

Distance from center of holes of rear support to rear of gearcase—11 1-8 inches.

Distance from rear of gearcase to end of drive shaft—2 1-16 inches.

Width of rear support—23 15-16 inches.

Crankshaft center to top of water connection—14 1-4 inches.

Crankshaft center line to top of fan—16 3-8 inches.

Crankshaft center line to extreme bottom of motor—7 1-2 inches.

Extreme width of motor exclusive of rear support—20 inches.

Weight without gearset, clutch, magneto, motor-generator and carbureter but with crankcase and oil base—285 pounds.

Weight magneto, motor-generator and carbureter—67 pounds.

Weight gearset and case, pedals and clutch—40 pounds.

Total weight power plant complete—392 pounds.

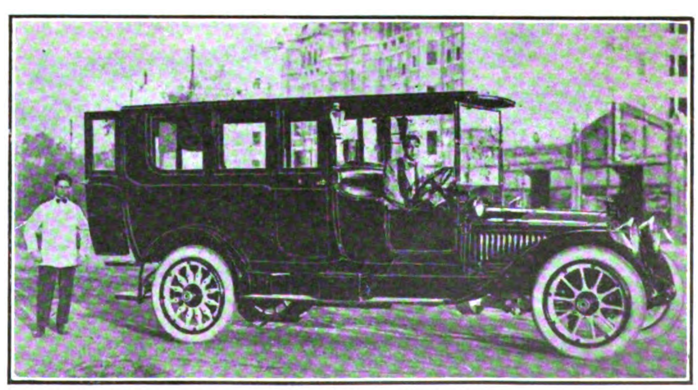
Valve diameter outside—1 13-16 inches.

Valve diameter clear opening—1 5-8 inches.

Valve lift—7-32 inch.

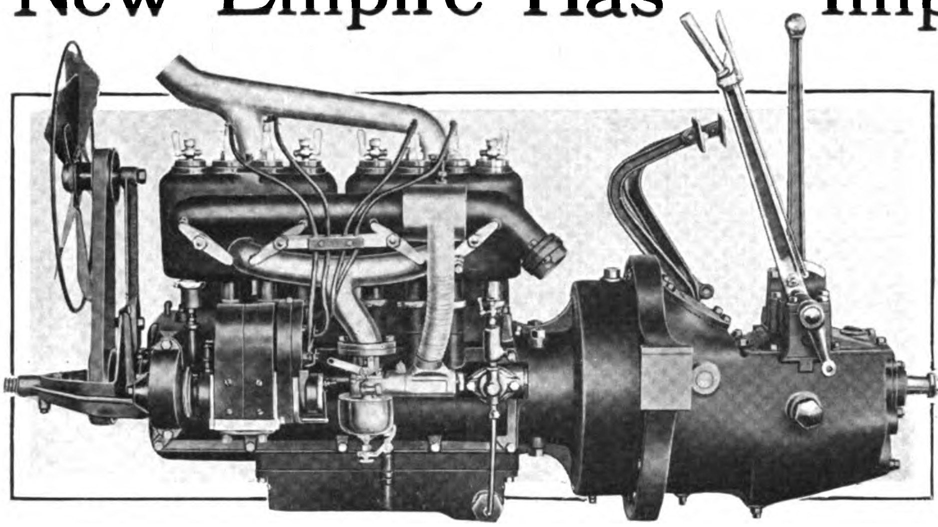
Big Packard Ambulance for Newton, Mass.

A luxurious ambulance has recently been delivered to a hospital in Newton, Mass., by the Packard Motor Car Co., Detroit, Mich. The ambulance is made up with a roomy closed body, electrically lighted, having ample windows for light and air, with doors on the side and rear and mounted on a 2-38 chassis. It has a gong, powerful searchlights, will climb almost any hill encountered on high gear, and is capable of great speed, with perfect comfort over rough going, a feature which doctors and nurses alike consider of prime importance.



Packard ambulance with roomy inclosed body

New Empire Has Improved Body



Unit power plant employed on Empire standard chassis for 1915

Price of Former Touring Body $50 Less—Line Comprises Two Touring Cars and a Roadster

WITH but few modifications the chassis made by the Empire Automobile Co., of Indianapolis, Ind., is the same as that employed for the past 3 years. The same body as that introduced for the 1914 season at $900 can now be purchased for $850. But, in addition to this, model 31-40, an improved streamline five-passenger touring car, is listed at $975. The streamline roadster, which corresponds to the latter in the two-passenger capacity, is sold at $875. In other words, the price has been cut $50 on the last year's design and a new five-passenger car added at $75 more than the car of 1914.

Remy Electric System

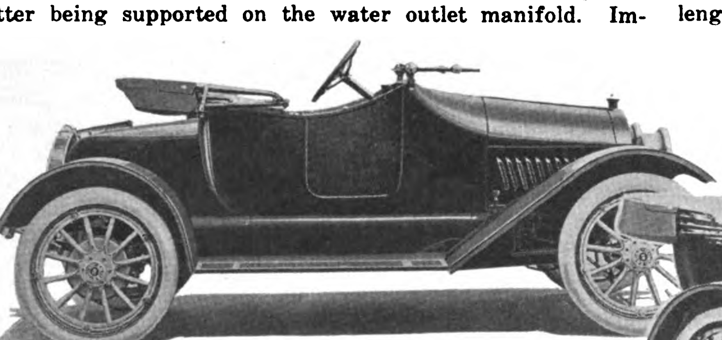
In bringing out this new design outside of the improved body work the most important change is the adoption of the Remy lighting, starting and ignition system. The mounting of this has of course caused minor changes to be made in the motor. But other detail changes have also been effected for this season. For instance, the oiling pump is now a horizontal instead of a vertical design and an oil pressure chamber is integral with the pump in order to maintain a steady flow to each of the leads. A priming cup is mounted on the oil pressure chamber so that in case the car has not been used for a considerable length of time, the pump can be primed to insure the delivery of oil as soon as the motor starts to run.

This season the fan post has been braced to increase its rigidity. A neater job has been made of the wiring, the latter being supported on the water outlet manifold. Improvement has been made in the clutch. Formerly the clutch adjustment was held by a number of steel plungers which fitted into holes in the clutch adjustment plate. These plungers were held in the holes by means of coil springs placed behind them. Now instead of the plungers, there are bolts, and when the adjustment has been made, the bolts are screwed down into the adjustment holes. This gives a much more positive adjustment lock than that provided by the plungers. Other than these minor details the chassis remains as it was.

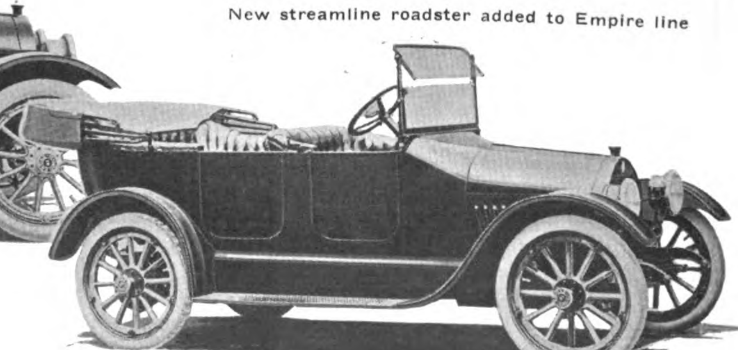
Right Steering Is Retained

A unit power plant suspended at three points including motor, clutch and gearbox is employed. The motor is a four-cylinder, L-head 3.75 by 4.5 unit, having a piston displacement of 198.8 cubic inches and stroke-bore ratio of 1.2. The cylinders are cast in pairs with separate manifolds, the water-jacketing space being large to take care of the needs of the thermosyphon cooling system. Unlike most of the motors for this season, the Empire has its valves all on the left side and this is accounted for by the fact that right steering has been retained.

Three rings and one oil groove underneath the lowest ring are used on the pistons. In the oil ring six holes are drilled to permit the oil sucked up by the pistons to return to the crankcase without being burned in the combustion chamber. These oil holes are .125 inch in diameter and are spaced equally around the circumference of the piston. The length of the piston is 3 9-16 inches. The diameter of the



New streamline roadster added to Empire line



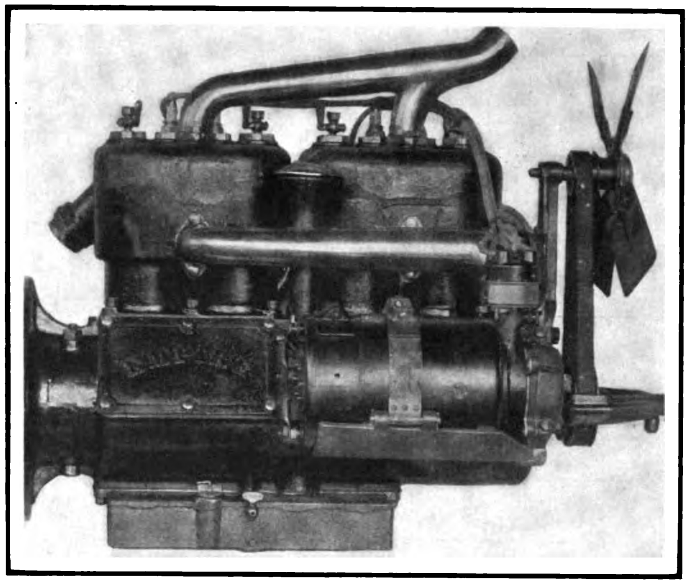
Model 31-40 touring car fitted with the new Remy electric equipment pin is .875 inch and the connecting-rod is an I-beam type.

Drop-forged crankshafts of high-carbon steel are used in all Empire cars. The diameter of the shaft is 1.75 inches and the shaft is finish ground to this size. It is carried on three bearings which are respectively 3.3, 3.3 and 4 inches in length from front to rear. These bearings are lined with white brass and have diameters of respectively 1.5, 1.5 and 1.625 inches.

Telescopic sleeves inclose what would be the exterior portion of the valve action. These sleeves can be raised, should it become necessary to adjust a tappet, by a single motion of the hand. In order to keep the tappets silent they are provided with fiber inserts. The valve action is driven from spur-type timing gears and the camshaft is a high-carbon steel drop-forging carried on four bearings. The valve diameters are 1.625 inches and the lift .3125. Nickel steel is used for the stems and cast iron for the heads.

Combination Pressure and Splash Oiling

A combination force-feed and splash oiling system is used. One and a half gallons of oil are contained in the lower part of the crankcase and from the reservoir the oil pump delivers the supply of lubricant to a three-unit sight feed mounted on the dash. At this point the oil is divided into three independent leads and flows to the three main bearings. After overflowing from the main bearings the lubricant drains into the splash troughs where it is picked up by the connecting-rods and thrown to the interior parts of the motor. It is a constant level system, the oil overflowing from the troughs as soon as it has reached the desired height. By using the oil drain holes in the pistons a copious supply of lubricant can be splashed into the cylinders without fear of smoking caused by the burning of the oil in excessive amounts during the explosion stroke.



Side view of motor showing the installation of the new Remy single unit system for lighting, starting and ignition

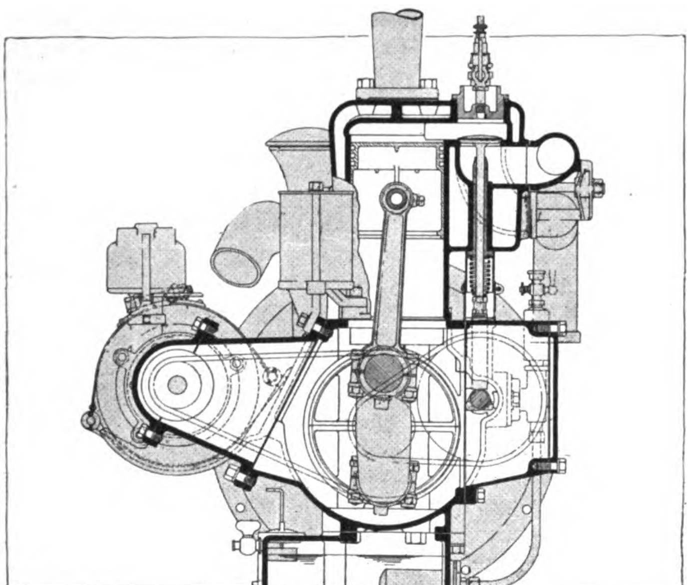
Special interest centers about the new lighting, starting and ignition system adopted by the Empire cars because it is a new product of the Remy factory. Known as model 129, it is a motor-generator outfit with battery ignition. The motor-generator is cylindrical in shape and is carried on the forward end of the motor, on the right side. A single armature with a compound winding operating at 12 volts performs the functions of a cranking motor and lighting generator.

When the starting switch is closed this unit operates as a compound-wound motor and turns the engine over at a speed of approximately 100 revolutions per minute until the engine fires. As soon as the engine starts running the unit becomes a shunt generator and at an engine speed of 350 revolutions per minute commences to charge the battery. At any speed above this the output curve of the generator remains flat at 6 amperes. The regulation is effected by means of a vibrator device which automatically increases and decreases the field strength of the generator. Both the relay and regulator are built upon an insulating block of bakelite and covered with a housing of the same material mounted on the engine side of the dash.

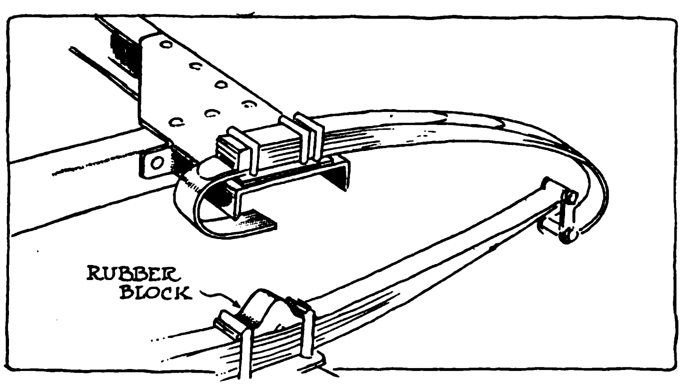
Generator Fuse a Safety Measure

Protection is afforded by a generator fuse which is also fitted to the insulating block of the relay regulator for the purpose of protecting the generator should the battery become disconnected from the charging circuit. If the battery should become disconnected the fuse will burn out, thereby opening the field circuit, rendering the generator inoperative. The entire system is wired by the single-wire method and each lighting circuit is protected by an independent fuse. The operator may determine from his seat whether or not the tail light is burning because the dash lamp is wired in series with it.

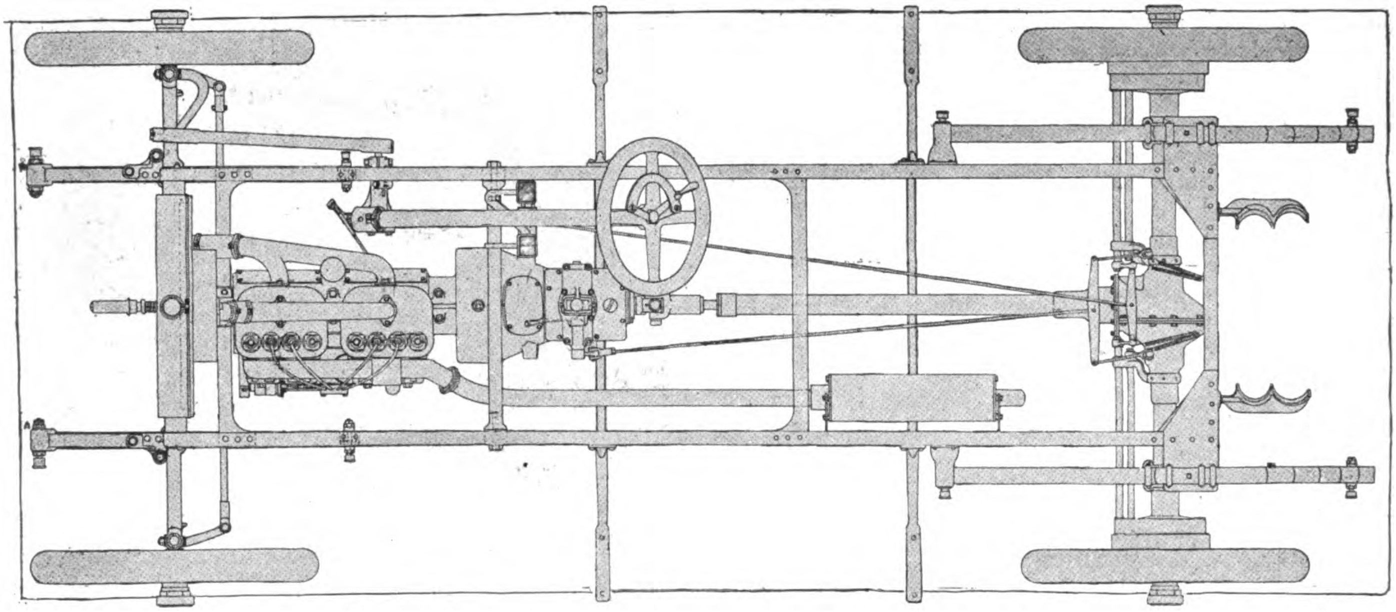
Ignition is by battery. Bakelite has also been used to good effect in the manufacture of the distributer. The construction of this system is such that the advance and retard motion does not move or oscillate the distributer and the wires attached thereto, thereby eliminating much of the chance of chafing and breaking the cable insulation. This system also operates at 12 volts and is designed throughout for that e.m.f. The coil is a special design for this voltage



Transverse section through the Golden, Belknap & Swartz motor used on Empire cars



Unique rear spring suspension a feature of the Empire

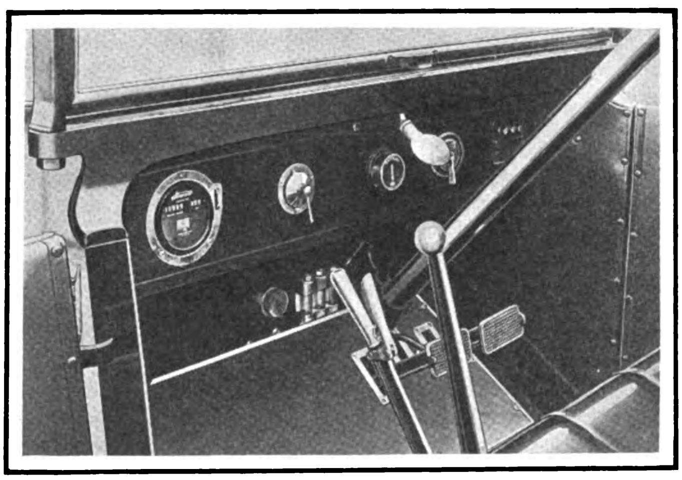


Plan view of chassis—Note three-point suspension of power plant and long straight brake linkage

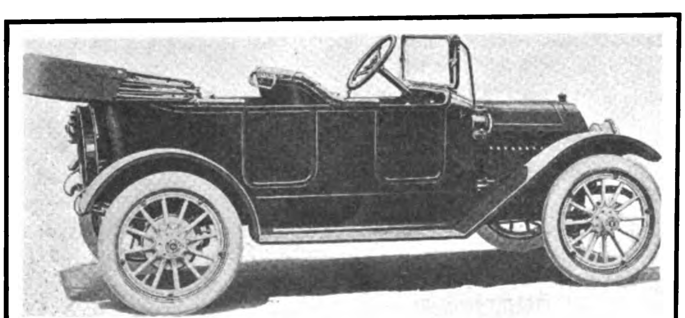
and has the advantageous feature of operating satisfactorily on a lower voltage should the output of the battery become low. The coil windings are heavily insulated and protected by bakelite.

The distributer segment arm, which is also made of the bakelite material, carries a safety spark gap to protect the distributer coil and high-tension cable. The circuit breaker is so designed that lag will be a minimum. In fact the makers declare that this has been altogether eliminated and that there is no time factor in the installation. A 12-volt, 50-ampere-hour, Willard battery acts as the current reservoir.

On the touring cars a 14.5-gallon gasoline tank is mounted under the front seat, giving a gravity feed to the Holly model-H carbureter. On the roadster bodies the tank is in the cowl and is of 12-gallon capacity, also providing a gravity feed. A 1.5-gallon reserve feature is incorporated in the touring car tanks. The carbureter is provided with hot-air intake and an air adjustment on the dash.



Dash showing mounting of control devices and instruments



Side view of model 31 tour'ng car which has been continued with a $50 reduction in price

A disk and ring clutch is used. It has three 9-inch disks, two of which are faced with Raybestos fabric and the third, that running between the other two, is of steel. The entire clutch is housed within the unit plant and runs in oil. It may be reached however, very easily by removing a large hand-hole cover which is accessible by lifting the floorboard in the driver's compartment.

Three-Speed Gearset

Three speeds are provided by the gearset. This is also accessible by a cover plate. The width of the gears across the teeth is .875 inch and on direct a final reduction between the motor and rear wheels of 4 to 1 is provided.

Only one universal joint is employed in the drive. This is mounted just behind the gearbox and is of the cross type. From this point the drive is taken through the steel shaft which is inclosed in a tube that is so constructed as to form a unit housing for the shaft and differential. The shaft is squared at the universal end and it may be quickly removed together with the rest of the entire rear system by removing the rear axle spring clips and detaching the brake rods.

The rear axle is a Weston-Mott semi-floating. The axle shafts are heat treated steel carried on heavy-duty Hyatt rollers. A noticeable feature in the axle housing is the utilization of a 3.5-inch sleeve bearing member which is hardened and ground. The axle carries a companion sleeve and the rollers bear upon these two members.

There are two sets of brakes. One expanding and the other contracting, acting on 12-inch drums on the rear wheels. The equalizers are mounted just forward of the rear axle. The brake linkage is distinctive in the employment of long, unjointed rods. The wheelbase is 110 inches, the tires 32 by 3.5 and the wheels twelve-spoke wood artillery.

The equipment on model 31, which is the held-over car, is practically the same as that on the model 31-40 except that acetylene lighting and magneto ignition are supplied instead of the new Remy outfit. Both cars have mohair tops, rain vision windshields, with a ventilating feature on the model 31-40, Stewart speedometer, etc. On the new car non-skid tires are provided on the rear.

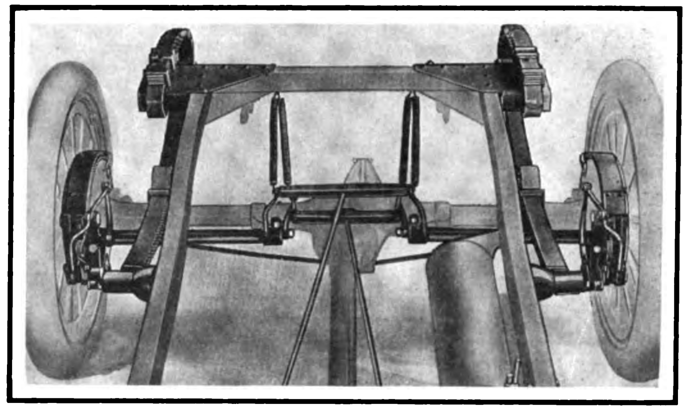
Apperson Adds New Four and Six

(*Continued from page* 667)

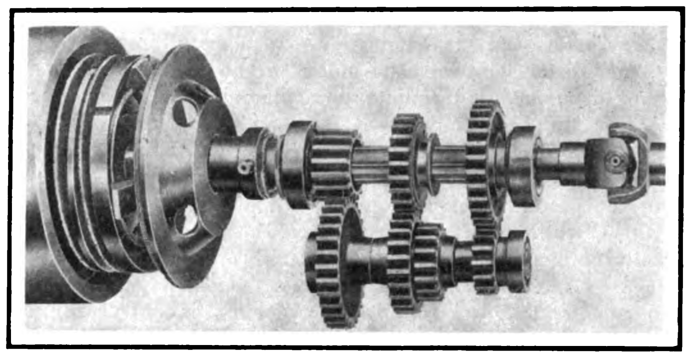
Equipment is full including a one-man top with dust cover and quick-adjustable curtains, rain-vision type of windshield, and full line of tools, lamps, license holder and so forth.

The two models which are carried over are known respectively as the 6-60 and the 4-45, the former being a six and the latter a four-cylinder design. These two cars are also similar in design but vary throughout in their dimensions. On the 6-60 chassis there are three lengths of wheelbase, 134 inches for the seven-passenger touring, 128 inches for the five-passenger and 122 inches for the roadster. These three cars sell at respectively $2,350, $2,200, and $2,200.

On the 4-45 there are two wheelbases, the touring car 120 inches and the roadster and coupé 116 inches. The prices on this are $1,685 for the touring car and roadster, and $2,350 for the coupé. Both cars have T-head block power plants, the dimensions of the six motor being 4.125 by 5 inches and those of the four, 4.5 by 5. In general chassis features they are the same as the two new cars which have been described. Both are equipped with the Bijur lighting and starting system, and have the single high-tension magneto ignition. They have the contracting band clutches, three-speed gearboxes, gravity gasoline feed, left drive and center control, and are fitted with bodies of streamline design. They are sold fully equipped.



Rear construction and equalizing mechanism on Empire



Assembly of clutch and gearset with universal joint

Six Detroit Electric Body Types—Two Chassis

(*Continued from page* 669)

As regards the controller, this has been re-designed to give easier action and more perfect automatic lubrication, the drum segments being lubricated by felt wicks dipping into a reservoir of oil in the controller casing.

The controller affords five forward speeds, which are 5, 8, 13, 17 and 20 miles per hour. The control is of the double voltage system, the battery connection being changed by the operation of the controller so that a low voltage is applied to the motor for the first three speeds and a high voltage for the two high speeds.

The springs used on the 1915 models are of the latest self-lubricating type in the leaves of which small indentations or cups have been made, these containing lubricant which serves to prevent squeaking between the leaves.

Another refinement is the use of battery hood props of a new design. Steel forgings which automatically drop into position and securely hold the hood raised, are used.

Gusset Plates Integral

The frame has been widened at the rear so as to better support the body and to give more battery space under the hood. An entirely new feature in frame design has been adopted in making gusset plates integral with the side rails, reducing the number of parts and adding to the strength.

Lamps are of the same design as previously used. However, a new style of bracket has been adopted permitting of making permanent soldered connections, while at the same time the lamps are adjustable. A dimming switch is provided for the front lamps.

The Engineering Digest

Methods for Brake-Testing the Power of Motors Without Dismounting Them from Car or Boat

SUGGESTING AN EQUIPMENT FOR REPAIR SHOPS

OCCASIONS frequently arise when it is desirable to ascertain the exact horsepower of a motor in an automobile or boat without going to the trouble and expense of dismounting the motor and placing it on a regular brake test stand. To diagnose shortcomings or make sure of the effects of a repair and for almost all experiments with carbureters and ignition devices, a convenient method for telling the power developed under each of the experimental conditions, while also keeping tests on the road available, is in reality indispensable, but the testing is usually foregone for lack of facilities or for lack of confidence in makeshift arrangements, and the repairs or the experimental results are permitted to end in something less than certainty as to what has been accomplished.

Th. Lehmbeck, authorized automobile engineer of Berlin-Friedenau, Germany, writes of the methods which he has found useful in such cases; substantially as follows:

The motor in a car is usually mounted so closely that the flywheel almost touches the drip pan, and in boats the distance from the flooring is also as a rule very small. It is therefore nearly always a bandbrake which must be used, and while it is not ordinarily recommendable to brake on the flywheel, an exception can very well be made for tests of mounted motors if the proper precautions are taken and the tests do not last more than an hour.

Even in some of the best automobile factories in conservative England the cable brake is still freely used for power determinations, and the method employed there suggests the simplest manner of proceeding, but it can of course only be used if there is clearance enough for the cable. The arrangement, as used in a factory, consists of a cast-iron stand with two bearings, mounted in these bearings a shaft with a broad belt sheave with side flanges, a rope about 30 millimeters in diameter wound upon the sheave with the two free ends reaching upward and attached to two spring scales. The shaft is connected by a clutch with the motorshaft, the motor is started and when it has been warmed up the spring scale on the side where the sheave pulls downward is tightened. The motor then draws the rope around till it begins to rub on the drum on that side while the other end of the rope loosens. The other spring scale is now tightened till it shows a few kilograms of load, by which action the load of the first scale will be increased consderably. After a few minutes a condition of equilibrim is reached, which can be recognized by a reduction of the motor speed taking place when the second scale is tightened further. By now deducting the load of the second scale from that of the first, there is obtained the real load under which the motor has been running. The motor speed being registered by means of a revolution-counter, the horsepower is now figured from the formula: HP. $= P\,N\,L \times 0.001396$, in which P is the effective load, N the number of revolutions and L the effective lever arm with which the load is working, or one half of the distance from center to center of the rope strands.

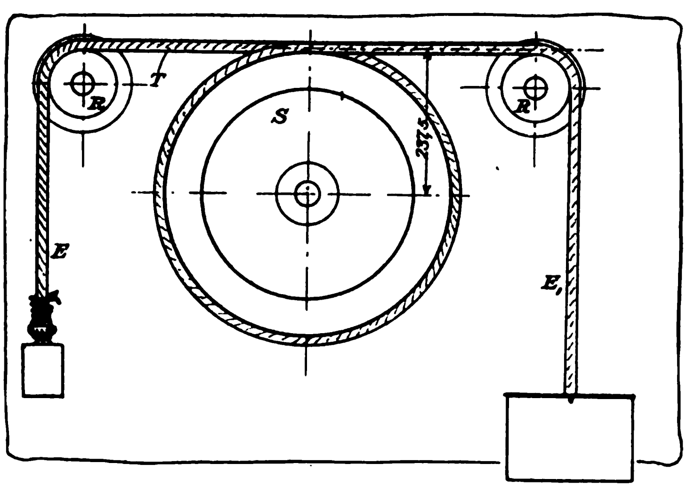

Fig. 1—Arrangement for testing by cable brake

The Makeshift Plan

In applying this method to mounted motors, the modifications indicated in Fig. 1 are introduced. The rope T is laid around the flywheel S and the free ends are led right and left over the two rollers R. Assuming that the flywheel turns in the anti-clockwise direction, customary in the case of automobile motors, a weight of 3 kilograms, for example, is attached to the end E, and at the other end E, there is hung a scale for the reception of the loads. Supposing the weight at this end is 12 kilograms, the effective brake load will thus be 9 kilograms. To prevent the rope from slipping from the flywheel, guide boards must be secured at both sides without touching it, and the friction in the journals of rollers R must of course be a minimum. Assuming the diameter of the flywheel is 450 millimeters and that of the rope 25 millimeters, the effective radius of the load becomes 237.5 millimeters, or, when expressed in meters, as required for use in the above-mentioned formula, 0.2375 meter.

The supposed data, with 1,150 revolutions registered by the counter, would give HP. $= 9 \times 1.150 \times 0.2375 \times 0.001396 = 3.43$.

Motors of up to 25 horsepowers can be tested in this simple manner without fear of burning the rope if from time to time a little soapwater is sprinkled upon the rope or the flywheel.

If there is not room for laying a rope around the flywheel, a bandbrake can be used on the plan shown in Fig. 2. To the two iron brake shoes A and B there is secured a leather belt of the width of the flywheel rim, and a strap of steel skelp, of the same width and 1 millimeter thick, is laid around the belt and made fast to the brake shoes as at 1 and 2. At its middle lower portion this strap is riveted to the leather belt, with the very flat rivet heads counter sunk in the leather so as not to project. Side guards of U shape, 40 millimeters broad and 3 millimeters thick, are also secured to the steel straps as shown in Fig. 2 at 3, 4 and 5.

The flywheel is here supposed to be 400 millimeter in diameter. To the upper end of the brake shoe A there is hinged the suitably shaped end of a ⅝-inch screwbolt which is about 200 millimeters long and is passed through an oval hole in brake shoe B. A spring washer, a valve spring of 100 millimeters length, 35 millimeters diameter and 3.5 millimeters wide, another spring washer and, finally, a handwheed H are mounted as shown, the handwheel being threaded upon the bolt, of course, and this leaves a free, smooth end of the bolt about 50 millimeters long with a hole for the attachment of a wire cable or the hook of a spring scale. In the case of a wire cable, which may be 3 to 4 millimeters strong, it is carried over a pulley and attached, as before, to a scale for the reception of weights.

The brake is first mounted loosely around the flywheel with the brakeshoes A and B about 50 millimeters apart, and the motor is run warm. A rope L is laid around B, as shown, and attached at the other end to something fixed, to prevent the brake from being carried around with the flywheel if it should happen to seize. When all is ready, the handwheel H is cautiously turned on till equilibrium is brought about, as before, the spring at the handwheel serving only to regulate the brake action. Oil is dropped on the flywheel occasionally during the progress of the test, so that the belt shall not burn on to it.

A belt of 5 millimeters thickness lasts at least for one test and cannot break during the test on account of the protecting steel strap.

For convenience in calculations the distance from center of flywheel to center axis of the screwbolt should be made 358.1 millimeters, as this simplifies the formula HP = P N L $\times$ 0.001396 to HP. = P N $\times$ 0.002.

The figuring can in this manner be done mentally. For example, the motor makes 1,300 turns per minute with a brake load of 22 kilograms, and this gives a power of 11 $\times$ 1.3 = 14.3 horsepowers.

When a bandbrake is used, the lever arm cannot be made longer than the 358.1 millimeters referred to, unless one can work with a securely fixed rigging, but the arrangement suffices for most cases and gives results which are accurate enough in practice.

It goes almost without saying that for tests of a motor in a car the vehicle clutch should be out of action.

With regard to tests of motors in boats it need only be said that they should be made with the boat in the water, as the air and carbureter conditions here differ from those obtained in a closed room. Also, any test should be made once with the propeller shaft disengaged and again with this shaft turning in its bearings, as the water pressure upon the structure of the boat may affect the friction in this element very considerably.—From *Auto-Technik*, May 23.

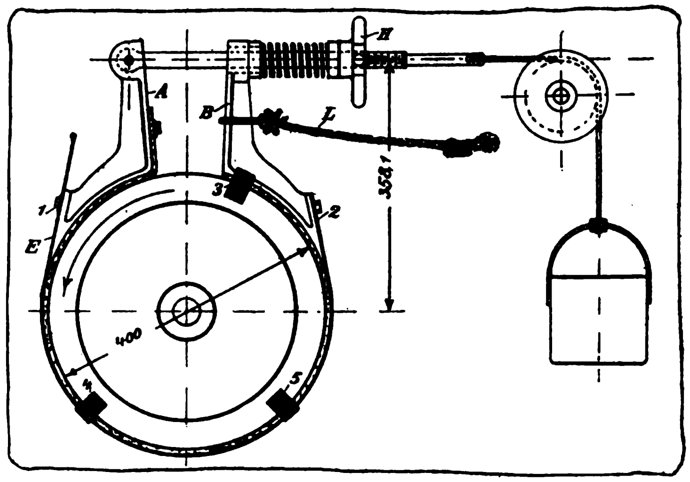

Fig. 2—Band brake test for mounted motor

Pointer from British Practice on the Chances for Disk Wheels

VAUXHALL Motors, Ltd., a British manufacturing firm, points out that the recently introduced aluminum disks appear to have increased the popularity of wire wheels, especially among drivers who have so far been unfriendly to them on account of the difficulty of cleaning. The disks are conical, to cover and inclose the whole axle end, and light is reflected from them along two radial lines, with the slant of the cone in them, producing an effect more pleasing than any which can be obtained from flat disk wheels. If it is a true fact, as stated, that objections to the disk type of wheel can be so easily overcome, so far as appearances are concerned, as to make it advisable to transform a wire wheel into a disk wheel by means of a conical aluminum cover plate, those who hesitate to employ steel disk wheels for trucks and other commercial vehicles merely because they are afraid of popular objections to the type may now find encouragement for developing the steel disk wheel to what it should be in the matters of strength, light weight, sightliness and freedom from resonance or other noise. In the French war trucks equipped with this class of wheels no objections have been publicly recorded with regard to their reliability, though in these cases they are equipped with solid rubber tires, but it is not to be denied as yet that the air tires—which of course are the only kind used in connection with the Rudge-Whitworth wire wheels with aluminum disks for pleasure cars—obviate resonance and noise much better than solid tires could do, and, by the same token, protect rivets against working loose. The conical form should have a certain influence to reduce noises, as well, but a relatively soft cushioned seating for a solid rubber tire, such as is already used in some delivery wagons and trucks, would perhaps be the most effective expedient to adopt in this respect, where heavy commercial vehicles are concerned.

Malleable Nickel Coating for Aluminum by the Canac Process

THE difficulties experienced in providing aluminum with an adherent coat of nickel are well known. Usually, when it is desired to make the deposit by the electrolytic process, an intermediary metallic coating is required, and copper, zinc or iron is generally the metal first precipitated. Naturally the pickling of the aluminum which must precede the process plays an important part but despite all care taken in this operation the nickel coating produced is far from presenting the guarantees of permanent adhesion which would be desirable.

Among methods recently developed, however, one devised by J. Canac circumvents the need of a first coating with another metal and results in a nickel coating so firmly adherent that aluminum sheets provided with such a coating have been placed in the market under the name of aluminum-nickel, although there is no question of an alloy. And these sheets can be used as a raw material to be worked into new forms and articles.

The preliminary pickling of the aluminum is elaborate, however, and comprises the following operations:

(1) Immersion in a boiling bath of potash, (2) brushing with milk of lime, (3) dipping for a few minutes in a 2 per cent. solution of cyanide of potash, (4) exposure to the action of a bath composed of 500 grams of hydrochloric acid, 500 grams of water and 1 gram of iron, until the aluminum takes on the appearance of damascened metal.

After each operation the aluminum is washed in water.

With regard to the composition of the nickeling bath, the following ingredients give good results: Water 1,000 cubic centimeters, chloride of nickel 50 grams, boric acid 20 grams.

The aluminum-nickel will bear hammering; the sheets can be curved or spun without cracking and it is only by fracture that the aluminum can become exposed. It can be heated up to the fusion point of aluminum without deformation.

In *Revue de Métallurgie* for June Mr. Tasilly examines the nature of the adhesion between the two metals caused by the Canac process. He finds that a light deposit of iron is formed upon the aluminum sheet when it comes out of the iron-containing bath, and it seems that this iron by forming a network on the surface of the aluminum sets up a multitude of terminals which favor the attack by the hydrochloric acid at certain points. The result is a peculiar appearance of the aluminum surface involving a new capacity for holding the electrolytic deposits.

The nickel which is deposited under these conditions takes root, so to say, in the aluminum and forms one body with it so perfectly that it is impossible to detach the nickel without tearing off at the same time particles of aluminum. The metal so treated does not change in moist air, resists chemical actions very well, is nowise affected by wine or alcohol and does not sweat gasoline or kerosene contained in a vessel made of it.

Aluminum-nickel made by this process can thus be employed in all cases where there is use for a light, resistant and unchangeable metal; as for railway appliances, canoes, automobiles, aeroplanes, physical instruments, photographic apparatus, household and travelling utensils.—From *Génie Civil*, September 12.

New Light Built-Up Steel Wheel Received with Acclaim

A STEEL wheel, built along the lines of present artillery wooden wheels, has been invented by W. Starley, an Englishman, and its manufacture has been taken up by The Jointless Rim Co., Ltd., Birmingham, Eng.

The Autocar, which hails this new wheel as something of great importance to motordom, states that "the essential difference between the new wheel and other steel wheels is that it is built up with separate hollow spokes, which are attached to an ordinary steel tire rim at their outward extremity and wedged together at the nave as in a wooden artillery wheel.

"The ten spokes have a U-section and are pressed from flat steel plates, the rounded portions of the spokes being on the outside. The open or inner side of each spoke has a flat plate, welded to it, completely closing it, the welding being done by the oxy-acetylene process. The nave end of the spoke is tapered just like a wooden spoke. When the ten spokes are assembled, the taper leaves a slight space between adjacent spokes, the opening being the widest toward the center. These taper spaces are, in the process of assembling, filled with steel wedges. The outer ends of the spokes fit over small lugs, which are let into the tire rim from the under side and afterwards riveted over. No welding or brazing is required at the rim, as the hollow spokes fit over the lugs and remain firm.

"When the wheel has been roughly assembled, the tire rim is placed in a large vise which grips it at three points, which the wedges already referred to are driven into. This produces a tendency in the spokes to spread, but, being prevented from doing so by the rim, and interlocking with one another at the nave, the wedging action results in the spokes becoming firmly locked together. After the spokes are wedged the center is bored out to a circle, and inside a groove is turned into which is spun a steel liner. This, in turn, is bushed with brass, to prevent rusting.

"A steel flange is fitted on each side, being held in place by spinning over the ends of the steel and brass liners. The lateral strength of the wheel, does not, however, depend on these flanges, which are only fitted to give the wheel a finished appearance. The outer flange is fitted with a brass hub cap so that car makers are not even called upon to provide this; they have nothing to do except to fit the wheels to their hub-shells.

"The methods of attachment is that known as the stud system, each alternate spoke being drilled for the studs or bolts and a cross liner of brass fitted into each hole to prevent rusting and to act as a driving support for the stud.

"Before assembling and after completion the wheel is treated by the Fermangan anti-rusting process inside and out. The total saving in weight in a set of five 26 by 3-inch wheels is about 13 pounds.

"This wheel would seem to not only have the stability and strength of the wooden artillery wheel, but the heat radiating, and resilient qualities of the wire wheel." On the other side it is not to be forgotten that a very high factor of safety is required in a wheel depending for its strength on oxy-acetylene welding of small steel parts and on wedge action of other steel parts, both these elements calling for highly skilled workmanship to secure uniform results.

Sensible Methods of Suppressing Reckless Driving

IN the early summer numerous automobile accidents occurred on the Boston Post Road within the town of Greenwich, some of which resulted fatally. As this part of the road extends from the city of Stamford to the New York State line, a number of drivers would "open up" their cars, feeling that they could cross into New York State before being caught. Saturday and Sunday evenings when the tourists were returning to New York and New Jersey were the times when the most flagrant cases of speeding were observed.

The authorities of the town of Greenwich decided to put a stop to this reckless driving and put the matter in the hands of four constables headed by Alden McMurtry of Sound Beach, Conn., a prominent member of the Society of Automobile Engineers. Various traps were measured and a system of signals was arranged for timing.

The state law provides that any speed greater than 25 miles per hour shall be *prima facie* evidence of recklessness. However, if the driver could prove to the satisfaction of the court that at the time of arrest his car was under absolute control, that the highway was clear and that there were no intersecting roads or dangerous turns, it would be doubtful if the charge against him could be sustained, as *prima facie* evidence merely places the burden of disproof on the accused.

A form of schedule was agreed upon after making a number of tests with a large five-passenger touring car, as follows:

Trap A. Speed limit, 35 miles per hour. With muffler cut-out open (unlawful), 30 miles per hour. Passing car going in same direction with car approaching in opposite direction, 30 miles per hour. With cut-out open, 25 miles per hour.

Trap B, located on turn. Limit, 25 miles per hour; cut-out open, 22 miles per hour. Driving turn on wrong side of road although clear, 20 miles per hour.

While an absolute schedule was established, nevertheless a great amount of discretion was used. In the majority of cases a gentlemanly warning regarding the consideration of other users of the highway, etc., had more effect than a troublesome arrest and fine. However, the speed-mad drivers were given no consideration, and heavy fines were imposed. This form of crusade against recklessness has resulted in less than twenty-five arrests during the period from May 17 to September 1. The considerate drivers may run along at 30 miles per hour, provided they use discretion on certain parts of the highway and in congested sections.

Bank Accounts of Ford Employees Gain 30% in 6½ Months

Records of the Company Show That Individual Efficiency of Employees Is Increased, While Living Conditions and Health are Greatly Improved by Operation of the Profit Sharing Plan Adopted Last January

DETROIT, MICH., Oct. 2—The working out of the Ford profit-sharing plan was the subject of a talk by John R. Lee in charge of the sociological work of the Ford company recently in this city. Mr. Lee analyzed every phase of the system, showing how the Ford company has taken up every department of the work and how each workman is individually investigated in order to make certain that he is eligible for participation in the plan. Mr. Lee showed that within the first month 60 per cent. of the workmen were participating, this notwithstanding the fact that the working force of the company approximated 20,000 and represented forty-nine different nationalities.

In order to facilitate the work of investigating the different employees it was necessary to start a school in which the English language was taught, there being upwards of 1,000 enrolled in this at the present time.

The economics of the profit-sharing scheme was proven by the fact that after it had been in operation for 7 weeks it was possible to build more cars with fewer men and working fewer hours per day.

Men's Health Improved

As to how the profit-sharing plan is actually working out for the benefit of the worker, the report shows that after 6 1-2 months' work the bank accounts of the employees had increased 30 per cent. Of still greater importance was the fact that punctuality and regularity had increased to a remarkable extent and the general health of the employees was improved.

Mr. Lee said in part:

"The Ford Motor Co. was first incorporated under the laws of the State of Michigan, January 16, 1903. It was originally capitalized at $100,000, which was subsequently increased by a stock dividend of a very large surplus to $2,000,000. The company started its incorporation with $28,000 in cash, and this has taken care of the corporation since it started, that is to say, nothing outside of this $28,000 was ever taken by the company in the way of money.

"The plant in Detroit, together with its various branches in different parts of the world, covers approximately 150 acres, and represents some 7,000,000 square feet of floor-space.

"For the year ending October 31, 1913, the gross business was $90,000,000, or it represented 165,000 cars, and the profit thereon was in the neighborhood of $20,000,000.

"From September 30, 1913, to the present time, the gross sales have been $110,000,000, representing 226,000 cars, and the rate of earnings the same, showing an increase over preceding periods, notwithstanding the fact that the price of the finished product has been materially lessened and our profit-sharing plan has been in operation since January, 1914.

Forty-Nine Varieties Work

"The working force of the company is about 20,000 altogether, and at present represents forty-nine different nations or countries of the earth. I give you these facts, and the following names of countries our men represent, in order that you may a little better understand our problem.

"The men we have working for us represent the following nationalities: American, Polish, Hungarian, Italian, Spanish, English, Irish, Welsh, Scotch, Russian, Greek, Turk, Bulgarian, Dutch, Belgian, Swiss, Norwegian, Swede, Dane, Finnish, Japanese, Chinese, Australian, Macedonian, Persian, Negroes, Indians, Canadian, French, German, Servian, Austrian, Mexican, all the South American countries and Central America, forty-nine in all.

An 8-Hour Day

Sixty per cent. of our employees speak English and 33 per cent. are citizens of the United States. The ages of our employees are from 16 to 75. We are operating a so-called open shop. Our work is all done on per diem basis, that is to say, at an hourly rate. We have no piece work, or bonus system. We work 8 hours out of the 24. We have some departments requiring two shifts, some three.

"Our profit-sharing plan differs from all the other profit-sharing plans of which we have any knowledge in all its features. Let me state here that it was not inaugurated or planned, or put into operation, as a business expedient in any way whatsoever.

The aim of the Ford Motor Co. in arranging for the gigantic step was to better the financial and moral condition of each employee and those dependent upon them.

"The money that is paid employees under the profit-sharing plan comes to them regularly in their pay envelope, to be used, and by use thereof they are acquiring American ways, methods of business, strength of manhood, loyalty, and improvement in their conduct of self as citizens of the United States.

"There is no stipulation or proviso, whatever, in the plan which deprives an employee of anything given him under it, should he see fit to sever his connections fairly and honorably with the company at any time. It is required, and is the object of this plan, that the employee shall use the money given him as his part of the profits in ways which will not harm or be a detriment to himself, or to society at large.

"There are three groups of eligibles:

"First: All married men, living with and caring well for their families.

"Second: All single men past 22 of good habits.

"Third: All women or single men under 22 years, living with and sole support of some next of kin.

The Sharing of Profits

"The statement ordinarily made that the minimum wage is $5 a day is not correct. We pay for 8 hours' work approximately 5 per cent. more than they would receive at any other shop for 10 hours. Then they add to that enough to make up the $5. Those men in the factory who are getting up to and including 38 cents an hour come under the $5 class. Those getting from 38 cents and up to and including 48 cents, receive $6 per day; those receiving 48 cents an hour or over, receive $7 a day.

"On this basis, for example, if a man's wages amount to $2.75, add to that $2.25 as his share of the profits, which is paid

to him on his regular pay day in cash.

"We make a sharp distinction between amount of wages and profits, in order that the benefits of the plan may be safely, sanely, and positively appreciated in each individual case.

Profits Sometimes Withheld

In the operation of the plan, we are finding many cases where it is necessary for the general good to withhold profits from some of the men, and in many cases to take away from them all of the profits already granted until they can fully realize the advantage of same.

"In order that the facts above stated can be fully understood, would say that up to date we have recovered the sum of $7,000 paid employes who obtained their profits under false conditions, or were using them in some way detrimental to themselves and others.

"The true foundation of this plan was conceived a little prior to January, 1914.

"The Ford company began to recognize the human element in the three-fold phase of manufacturing, men, material and money.

"We are working today instead of 9 hours a day, 50 hours a week, and have increased the wages 15 per cent.

"We have a systematized rating according to skill or ability, and indemnify each employe against petty discrimination by the foreman, and have arranged a clear cut simplified scale of wages.

"When a man fails to get along in one department, he is sent to our employment department, and there questioned closely to make sure of the fact that he is not undesirable and an unworthy individual. At this place, he is given another trial in some other part of the factory.

Investigating the Worker

"Each employe has been at some time investigated, at the time of employment or some time subsequently, and a record taken as to his financial condition, his place and method of living, his occupation, those dependent upon him, kind of recreation indulged in, his habits, age, religion, home conditions, neighborhood, ambitions, what he intends to make of himself, if anything. These data are gotten by men from all sources, from himself, his wife, his pastor, church records, etc.

Teaching English Language

"The working out of all this has presented very many problems. The fact that so large a percentage of the men have no knowledge of the English language made it necessary for the company to establish a school for enlightening them. We have now enrolled about 1,000 men, who are being taught English by the Roberts system, teach him the ways of American citizens, even to purchasing and handling of property, etc.

"To gather information from employes, we organized first a band of about 200 men. We have sifted this band of men now down to twenty men, and after examination all stand high in gentlemanly qualities, tact and diplomacy, human interest, conception of the profit-sharing plan.

"Each man is kindly and thoroughly brought to see, if possible, the benefits of better manhood and better standard of living, if he be unable to appreciate them for himself. We try to teach them self-respect and care for home and children.

Many Interesting Cases

"We have found many interesting cases since beginning in this work, and I will tell one of them here. A great big chap weighing 250 pounds walked into the office one day. I asked him what he wanted. He said, 'I am so and so, and I want to know why I don't get $6 a day.' We sent for his time sheet, and found he was one of our foremen. We asked him a few questions. He said he thought he had a mother, but he didn't know where she was; there was no one dependent upon him. We asked him if it wasn't true that he paid his board 2 weeks in advance, put the rest of his change in his pocket, and just let it seep out, etc. 'Well,' he said, 'what of it, what ought I to do with it?' 'Well,' I said, 'You have got to prove to us that you have some of the elements of thrift before we give you this money.' He said, 'What have I got to do? I don't know how to start.'

"We suggested that he look up his mother, etc., and that he had to be thrifty.

"He got to the door and turned around. He says, 'I was a bum once and I may as well be again—you don't appreciate me around here.'

"We found he was a very responsible employe, and told him to go out and see if he couldn't find himself. He came back in 6 weeks, and handed me a letter from his mother full of gratitude and delight to think that he had come to her again, and acknowledging receipt of $25. She said she never had anything do her so much good, said she didn't know whether he was dead or alive, and was so glad to hear from him, particularly as she needed the $25, as she had been living around among her friends without any money. He showed me a receipt from a tailor, showing that he had paid $8 on a bill about 8 years old; then a receipt from some lodge he belonged to, and last of all, he showed me a bank book with $40 in it.

"We immediately approved him for his share of the profits, and it is the most gratifying thing in the world to see him living here in Detroit with his mother, with his bank account growing every day, and a man altogether satisfactory to us in the shop, improving in his work, and he now wants to be enrolled as an instructor in English in our school, and we are going to enroll him.

60 Per Cent. in First Month

"The figures showed after the first investigation taken about Feb. 1, 60 per cent. of the men were receiving profits, because they seemed from the records to embody the necessary qualities to receive and use the money under the plan according to the purposes of it.

"We have just completed Sept. 1 investigation, and this percentage has grown from 60 per cent. to 82 1-2 per cent. of the total force. The other 17 1-2 per cent. represents the ineligibles, or men whom we are still working upon, but up to the present time are not qualified to receive the money.

Fewer Men, More Cars

"In the month of February, 1913, with 16,000 men working 10 hours a day, we built and shipped 16,000 cars. In the succeeding February, after the profit-sharing plan had been in operation 7 weeks, with 200 men less, working 2 hours a day less, we built and shipped 26,000 automobiles. It is true that the giving of a portion of the profits to each individual qualified is not entirely responsible for this tremendous increase. Much is attributed to improved methods. Of the 44 per cent. increase, 25 per cent. is the proper amount to credit to the men.

Bank Accounts Up 30 Per Cent.

"On August 1, or about 6 1-2 months after the plan was inaugurated, a gain is shown in the bank accounts of our employees of 30 per cent.; in the amount of life insurance, 86 per cent.; homes bought and paid for, 87 per cent.; lots bought and paid for, 86 per cent.; homes bought on contract, 75 per cent.; lots bought on contract, 135 per cent.; and payments made on contracts for lots, 145 per cent.; amount of rent per month, 12 per cent.; amount of board per month, 11 per cent.

"These last two figures are interesting, inasmuch as they show that the men have moved out of squalid quarters into neighborhoods where conditions were better.

"We have a directory, somewhat on the plan of our city directory, and have made a map, showing districts inhabited by our employes. Each section is marked according to the character of the residents.

"Punctuality and regularity of attendance is present to a surprising degree, and this has solved many, many problems that were more or less vexatious in our various departments. Spoiled work has greatly decreased, and our medical department tells us that our men, as a whole, have gained in health since January.

"It is perfectly natural for men to wonder about the permanency of this plan, and we can only say concerning it that it is the outcome of a business which for 11 years has been built by perseverance and with all the conservative judgment that the human mind is capable of. The Ford company has laid plans so that the profit-sharing plans, or rather toward men-making plans, shall endure, and also plans have been started which will bring about a still better condition for these men, firmly convinced of the wisdom of the saying, 'Whatsoever a man soweth, so shall he reap.'

Study Men in Factory

"We watch the individual man in the shop just as much as we watch the product and each individual machine; in fact, we watch our men three times as much as anything else.

Six Grades of Men

We have six grades. We have also some forty-eight different rates of pay that we apply to different skill throughout the shop, and we boiled them all down to eight. A man starting with us here as a skilled operator in the B class goes in as a B-3 operator at 30 cents. We watch him and as soon as he improves he is placed in the B-2 class. He doesn't have to wait upon the tender mercies of his sub-foreman, but is watched from the time department, to see that he is advanced when he deserves it, and his wages will be raised from 30 to 34 cents.

"The table herewith represents a survey of 13,304 men, not quite all of the force here at this time. The majority of the men fall into the C and B groups, these are machine shop operators and average men throughout shop. These groups, A, B, C, are producers, D are helpers, plumbers, steamfitters, etc., E is the common laborer. We pay the laborer, unproductive, one rate. We have a special grade for messengers and some women in our employ. This whole scheme has given splendid results.

Investigate Each Man

"We take his name, his residence, married or single, speaks English or not, religion, recreation indulged in, birthday, lived in Detroit, how long, number of children, names and ages of children, names of persons dependent, how much they earn a week, number at school. This information we do not use at all in the consideration of the fitness of the man, but you can imagine that in going among all this foreign element to get the truth, we had to have something or other to throw light on the man, to be sure that the data he gave us about his family and people dependent upon him was right. For instance, we ask a man if he is a Catholic, and what church he goes to. We go and consult the priest. We find many who say they are married are liars.

Ford Motor Co. Employees

	Dec., 1912	Oct., 1913
Five-day men	3,594	322
Men discharged	776	137
Men quitting	386	326
Men laid off	4,822	844
Total hired	5,678	1,789
Gain for month	856	945

How Banking Grows

"The Ford company has been charged with influencing its employes to deposit their savings in Highland Park State Bank, stock of which is owned largely by members of the company. Only 28 per cent. of the savings of employes since the profit-sharing plan was inaugurated were shown as having been deposited in Highland Park State Bank. The other 72 per cent. were in other banks throughout the city.

"Bank deposits have increased 80 per cent. since the profit-sharing plan was started. Of the American employes, 609 have no accounts, 2,280 have bank accounts, aggregating $462,411, an average of $202.81.

"The Irish come in pretty strong, with an average of $291; the French and Hollanders with $304, and the prize deposit is held by a Hindu and is $575.

"Out of 2,889 Americans, 1,631 have life insurance. Several nationalities, Greek included, do not believe in life insurance, as not one man out of whole numbers of those nationalities employed carries any insurance.

Making Citizens

"Bank accounts were shown by religions. Out of 9,501 men 6,175 speak English, 3,076 do not and 3,640 out of this number are naturalized citizens. We are trying to prepare thirty men weekly for citizenship.

"The Americans predominate in owning homes and lots, although they do not always predominate in average value, as we look through the columns of our investigation records.

"The percentage of good homes at the first investigation was 47, and on the second, 69 1-2. The fair homes at first were 39 per cent. and on the second investigation, 29 1-2 per cent. Poor homes at first showed 23 per cent., but on the second investigation had declined to 1 1-2 per cent.

"Neighborhood conditions have improved from 41 to 57 per cent., the fair jumping from 40 to 40 1-2 per cent., while the bad declined from 19 to 2 1-2 per cent.

Our Opportunity

BEING prepared when the opportunity comes is a great secret of success. In business the young man, filling satisfactorily his $25-per-week job, will only be assured of the job higher up, if when the vacancy occurs he has prepared himself and is equipped and ready for the higher duties. In proportion as he has prepared himself for such will his efforts meet with the highest success.

So in our industrial worlds, conquests were never made by looking around, whining and wringing the hands. This is a world of activity, one in which "art is long and time is fleeting." A world in which favorable business conditions are not made specially for the individual concern, but in which the condition is open to all and only those profit who are ready when the opportunity comes.

The Opportunity

Such a business opportunity has presented itself to the American motor truck industry. Foreign powers are buying trucks and the demand came in the twinkling of an eye. There was no herald 6 months ago announcing from New York to Chicago that in September and October Europe would buy trucks in quantities that would keep many factories working on night-and-day forces, rather the chapter of opportunity was penned in a single week, and the final decision arrived at in one short day. Yesterday there was scarcely a symptom of need for American trucks in Europe, yet today the demand is here.

A few concerns are going to profit well by this opportunity, they are going to profit because they are ready for the opportunity. During the past months they have been cutting their cloth to meet requirements, doing business by going out in the highways and compelling it to come in; whereas others have talked depression, have looked on the great expense of American industry through the wrong end of the telescope and have allowed themselves to feed their own discontent. Such firms are today in a poor condition to meet the opportunity, which it is not necessary to cross the Atlantic to get in touch with but which has come to our very doors.

As Others See Us

Europe has examined our motor trucks during the past 3 weeks, and is today telling us our shortcomings as seen in the light of their experience. With Europe our trucks are too heavy, fully 20 per cent. heavier than those of France, Germany or England. This added weight is a direct handicap. We are today, and have been for 2 or 3 years, working for lighter-weight passenger cars, cars in which a great percentage of the motor power is not consumed in transporting the needless excess weight of the vehicle. We have acknowledged this situation, and have begun an era of higher efficiency in motors and the chassis in general.

The Springs

Spring suspension plays a much greater part in truck life than it is generally given credit for. Europe views spring suspension as a most important factor. If the spring system is not correct, you wear your tires too rapidly. The road wheels must hold the road. They must not bounce off the surface. Every time they bounce off the surface, the wheel spins or lags and there is tire wear. Hence, spring suspension becomes a vital factor in reducing tire wear, which is one of the most considerable factors in the expense of truck upkeep.

Wear

Ability to wear is the criterion that many foreigners use in the selection of a motor truck. Will it wear? This is the question they endeavor to solve. Parts must wear, and have they provision for adjustment? Can you adjust the bushings of the steering gear when they wear? It is cheaper to adjust than to replace. It is much quicker and in either war or industry the economy of time is a vital factor in truck operation.

So adjustment and accessibility become real factors in truck work. So Europe considers it, and as Europe is the big buyer today, it is quite necessary that these matters be conspicuous. But adjustability and accessibility are not important solely because Europe thinks so. Our own conditions demand them. Our industries demand such; and should our nation make large purchases of trucks for war purposes or determine on some form of truck subsidy system these factors would be equally important.

Horsepower and Gasoline War Tax Defeated by Senate Caucus

After Repeated Amendments to the Original House Measure Had Been Killed, Both Provisions Were Voted Down in Stormy Midnight Session—Victory May Be Only Temporary

WASHINGTON, D. C., Oct. 7—There will be no American war tax on automobiles and gasoline. At least, the provisions of the House of Representatives that would have collected 1 cent from the sale of each gallon of gasoline and 50 cents per horsepower for every automobile sold, were defeated late last night in a Democratic Senate caucus.

Long Fight Is Expected

It is expected that, in spite of the automobile and gasoline taxes having been thrown out by the Democratic Caucus, the House of Representatives will try to put them back on the bill. A long fight on the war revenue measure is expected to prolong the session of Congress. It is expected that the increased tax on beer, and 5 cents a gallon on rectified spirits will offset the loss on automobile and gasoline taxes.

The vigorous resistance of the automobile industry to the measures, in which it was shown that a necessity and not a luxury would be made to suffer heavily by the two taxes, probably influenced the senators and representatives.

The session was a tempestuous one and the discussion of the automobile tax caused the greatest trouble.

The vote of the caucus was 20 to 17 against the 1 cent per gallon tax on gasoline, the Senate committee having reduced the House assessment of 2 cents a gallon.

Among other changes in the original bill are:

The tax on chewing gum is 4 cents for each dollar box sold.

The committee added a tax on sparkling wines, not otherwise provided for in the bill, of 1 cent on pint bottles and 2 cents for bottles containing more than a pint.

It was decided to exempt from the tax all theatres and entertainments, chatauquas, lectures, lyceums, agricultural and industrial fairs and religious and charitable entertainments.

The committee estimated that several millions of revenue would be derived from the added taxes.

The first action of the caucus was to vote an increase in the proposed extra tax on beer from 50 cents to 75 cents a barrel, to make the total tax $1.75 a barrel, with a drawback of 5 per cent. for purchase of revenue stamps in advance. The amendment, urged by Senator Williams of Mississippi, was carried by a large majority after Senator Stone had made a vigorous speech against it. A special revenue tax on rectifiers of distilled spirits of 5 cents a gallon also was adopted. Together the proposed taxes on liquors would yield an annual revenue of more than $50,000,000.

Democrats of the Finance Committee had agreed to the House tax of $1.50 a barrel on beer, which would yield, at 50 cents over the normal tax, an added revenue of $32,500,000 annually. The further addition of 25 cents a barrel by the Senate Democrats would yield another $16,000,000. With the 5 per cent. discount for prompt payment figured, the least to be derived from beer would be approximately $46,000,000.

The proposed tax of 5 cents a gallon on rectified spirits, Treasury experts estimate, would yield $5,000,000. Thus the total to be derived from liquors would be more than half the anticipated Treasury deficit caused by the European war.

The caucus retained the stamp tax of 2 cents on Pullman car tickets. There will be no stamp tax on checks or other negotiable paper in this bill as approved by the Democratic caucus.

The caucus also revised the tax on banking capital. As framed by the Senate Committee, the bill would have levied $2 for every thousand dollars of banking capital and surplus. This rate was reduced to $1 per thousand by a vote of twenty-six to eleven.

Injustice of Bill Strenuously Argued by Industry

WASHINGTON, D. C., Oct. 6—The last draft of the proposed war tax revenue measure, as drafted by the three Southern Senators, places a tax of 1 cent a gallon on gasoline and 50 cents per horsepower on passenger, gasoline cars, this horsepower tax to be paid by the manufacturer or dealer, the tax to be paid by the manufacturer excepting under conditions where he has already contracted for the sale of his cars with his dealers, in which case it is expected that the dealer will have to meet the bill.

Alfred Reeves, general manager of the National Automobile Chamber of Commerce, was in this city today representing his organization, and hoping to make a date for a public hearing on the measure. A public hearing was denied and he was granted a conference with two of the Senate committee, Senator Simmons of North Carolina and Senator Williams of Mississippi. Senator Gore of Oklahoma, the third member of the committee, was not present.

The committee acknowledged to Manager Reeves that more pressure was being brought to bear against the gasoline tax than had been brought against any similar measure in Washington. Practically all automobile manufacturers, all accessory manufacturers, all automobile dealers' assns., and a great many of the large automobile and supply dealers have forwarded telegrams to the committee. Scores of other organizations have forwarded their resolutions and from all sections protests have arrived against the measure.

Governor of Michigan Protests

Governor Woodbridge N. Ferris, of Michigan, sent the following telegram today to U. S. Congressman Underwood:

"Proposed motor car tax will in my opinion, strike a deadly blow at Michigan's greatest manufacturing industry. Michigan is loyal and patriotic, and ever willing to bear her share of the nation's burden. This industry is a Godsend to tens of thousands of laborers. Give us a tax that is not centralized —a tax that approximates a uniform distribution for those who have and to spare."

The reduction of the gasoline tax from 2 cents a gallon to 1 cent was brought about largely by the general protests not only from motor car manufacturers, but also from the thousands of farmers using stationary engines and gasoline engines used in power plants and other places. The sentiment is general that the present compromise of 1 cent a gallon on fuel will not be seriously disputed, but the horsepower tax of 50 cents per horsepower will be combated from the start.

What 50 cents per horsepower on gasoline passenger cars means to the automobile industry does not seem to be comprehended by the committee, which considers the gasoline pleasure vehicle solely a luxury and not a business necessity. The committee seems to be unanimous in the belief that there are scores of large automobile concerns making fabulous fortunes each year, and entirely neglects the hundreds of small companies that would practically be forced out of business by the horsepower tax.

Already the automobile dealer is taxed in many different ways, and the additional tax proposed by the Senate Committee would place an unreasonable hardship on many motor interests. For example, a dealer in automobiles in North Carolina, it is reported has at present to pay $500 per year for the privilege of doing business. To this we must add the various registrations that are required. Each state registers the cars and in many states personal property taxes on automobiles are paid; chauffeurs are registered in excess of horse drivers, and several states that have wheel taxes which are particularly burdensome. In the State of Iowa, with its 100,000 automobiles, it is estimated that the gasoline consumption is 75,000,000 gallons annually, which gives a revenue from this state alone of $750,000. It is not surprising that a general protest from all owners and dealers in vehicles should come from this state as well as others.

Many Send Objections by Wire

During the course of a speech in the Senate, Senator Smith read telegrams from many manufacturers protesting against the proposed tax. Herewith are presented some of these telegrams:

Nordyke & Marmon: "Proposed tax is the greatest menace to the industry in its history, owing to the contracts existing with dealers. Tax can not be passed on to consumers and will fall as an unjustifiable burden principally upon the states of Michigan and Indiana. Automobile manufacturing is one of the few industries that has kept the spark of industrialism alive in the United States during the long depression the country has been passing through. The automobile manufacturing industry as a whole is in no condition to stand this discriminatory tax."

Indiana Companies Protest

The Indiana Automobile Manufacturing Assn., the Hoosier Motor Club and affiliated clubs and workmen employed in the automobile factories of Indiana have also protested against the proposed tax on automobiles and on the capital stock of automobile manufacturing companies. Representatives of thirty-two motor car makers sent a telegram to Lincoln Dixon, member of the Ways and Means Committee, urging that he use his influence against such a tax.

Owners of cars and workmen joined the manufacturers in sending telegrams of protest to President Wilson, the Congress and members of the Indiana delegation in Congress. The messages state that practically all the motor cars built in the United States are manufactured in Indiana, Michigan and Ohio, and that hence the tax would be discriminating:

C. W. Nash, president Buick Motor Co.: "Senate committee's recommendation taxing owners and manufacturers of automobiles is the most serious blow that could be dealt this industry. We appeal to you to use all honorable means to save Michigan's greatest industry. Also request hearing of manufacturers before senate committee."

Hupp Motor Car Co.: "This seems to be vicious class legislation. No other industry has been singled out for such drastic and confiscatory action. The automobile must be recognized as a public necessity and convenience instead of a mere luxury. The hundreds of thousands of users of automobiles in the United States are entitled to the same fair and just treatment that should be applied to all other owners of property."

Chalmers Motor Co.: "We have already been forced to make a reduction in the price of our cars, due to conditions existing abroad and a tax of $40 per car would reduce the profit to a point where the successful operation of our company would be seriously impaired."

Studebaker Corporation: "The proposed special tax is intensely disturbing to the entire automobile industry. It immediately threatens the existence of numerous companies and the consequent elimination of income to many thousands of employes. Such an overwhelming blow to the automobile industry at this critical time would positively introduce wide disaster. There are approximately 1,548,350 automobiles owned in the United States, whose owners already pay property and state taxes. The majority of these cars are owned by persons in moderate circumstances and the use of these cars largely for business purposes makes them practically a necessity. The imposition of a third tax on motor cars and automobile owners is a positive burden amounting to discrimination. It is confiscation. The gravity of this proposed step and its far-reaching influences, which, in our opinion, can not have been adequately and thoroughly reviewed, makes a hearing in conference on this subject of vital importance and we respectfully request an early opportunity to lay before you important facts in connection with the proposed plan."

Cadillac Motor Car Co.: "Congress surely does not appreciate what would be the effect upon the entire automobile industry if proposed impost were forced. Michigan, in particular, would suffer a staggering blow. The automobile has become a commercial necessity for the whole country and its manufacture should be encouraged and not crushed. Michigan now depends largely upon the automobile industry for employment and thousands of Michigan workmen would become injured by such an unjust tax."

Federal Motor Truck Co.: "New proposed tax for motor truck manufacturers means suicide. Truck manufacturers in America to date have not made a dollar. Trucks are not a luxury; are sold on cost of installation and operation. Any additional tax will have lead effect on truck industry."

Henry B. Joy, president Packard Motor Car Co.: "Proposed additional tax is unfair and inequitable in the extreme. We now pay in taxes $35 on every vehicle we ship. Proposed tax would increase taxation to $75 each, an impossible, burdensome taxation."

Charles Thaddeus Terry, general counsel National Automobile Chamber of Commerce: "Automobile manufacturers throughout country protest against tax. Automobiles now pay three taxes. More taxes will destroy industry."

Imperial Automobile Co.: "If the proposed tax becomes a law you will ruin every automobile manufacturer in America."

In addition to the above, telegrams of protest have been received by Senator Smith and Senator Townsend from Stutz Motor Car Co., Briscoe Motor Co., Jackson Automobile Co., Abbott Motor Car Co., Anderson Electric Car Co., Briggs Detroiter Co., Commerce Motor Car Co., Cricket Cycle Car Co., Day Automobile Co., Dodge Bros., Ford Motor Co., Hudson Motor Car Co., Krit Motor Car Co., Regal Motor Car Co., Saxon Motor Co., Signal Motor Truck Co., Wagenhals Motor Co., Wahl Motor Co., Republic Motor Truck Co., Cartercar Co., Durant Dort Carriage Co., General Motors Truck Co., Havers Motor Car Co., National Motor Truck Co., Oakland Motor Car Co., Olds Motor Works, Reo Motor Car Co., and Detroit Auto Dealers Association.

Armored Cars for U. S. Army, Congressman Urges

WASHINGTON, D. C., Oct. 5—Some time this week Congressman Anthony, of Kansas, member of the House Committee on Military Affairs, will introduce a bill to have the United States army adopt and purchase armored motor cars as a regular arm of the military service. Several other members of the committee on military affairs have kept a close watch on the war efficiency of armored cars as described in the European dispatches and the sentiment at the Capitol is that the present war has demonstrated that this government can no longer afford to be without this equipment.

"To my mind," said Congressman Anthony to THE AUTOMOBILE correspondent, "there can be no doubt that any up-to-date army must be equipped with armored automobiles. The things that have been accomplished through their use by both Germans and the Allies have demonstrated that, as engines of modern warfare, they are indispensable.

"There was a time when people laughed at the idea of the automobile being a business asset, but only one glance at the country roads and wheat fields of my state, Kansas, is necessary to show that mistaken idea. And, since those nations which are recognized as having the most perfect military organizations in the world have demonstrated not only the efficiency but the necessity of armored cars, it seems to me high time for the United States Government to correct a defect which at any time might have the most serious consequences for our army.

"The time may easily come soon when much of the military work done by the horse will be accomplished through the instrumentality of the armored car. When this time does arrive it would be a great mistake to have this country behind all others in such valuable and essential equipment."

N. Y. Separator Repeal Law Defeated

NEW YORK, N. Y., Oct. 6—The New York City dealers and garagemen who have been fighting against the gasoline separator, the installation of which is required by an ordinance, were unsuccessful this afternoon in having the repeal of the separator law passed by the Board of Aldermen over the Mayor's veto. The vote was thirty-three to twenty-one in favor of retaining the old ordinance on the books; fifty-three votes, or two-thirds were necessary to override the veto. The board voted to repeal early in the summer.

This, however, does not mark the end of the fight. In pleading with the Board of Aldermen not to override the veto of Mayor Mitchel and repeal the ordinance, the Fire Prevention Bureau stipulated that it was perfecting a satisfactory separator than can be installed for less than $100 and would take no further action until this device was ready for the market; all present devices are declared by the garagemen to be expensive and not satisfactory after installed. As a further move, the appeal may be reattempted or a substitute ordinance may be introduced.

JACKSON, MICH., Oct. 5—The Argo Motor Co. has been incorporated. Capital stock $750,000. Benjamin Briscoe, president; Jas. R. Findlater, vice-president; F. D. Dornam, secretary; L. E. Latta, treasurer.

Not More Than 27,000 Cars in America South of U. S.

European Consignment Methods Described by Hupp Export Representative—Governments Selling Cars "Abandoned" in Customs

DETROIT, MICH., Oct. 5—"In all the countries south of the United States, that is Mexico, Central and South America, there are not over 27,000 automobiles, according to the most recent statistics which I have secured, and of that number about 15,000 are in Brazil and Argentina," said Peter Severin Steenstrup, export representative of the Hupp Motor Car Co. in South America, who is now visiting in Detroit.

"The automobile business in South America has really been overdone, and this is especially true concerning high-priced cars. The business is done mostly on a consignment basis with most of the European automobile manufacturers. Through their banks in the different South American countries they are able to investigate very quickly the financial standing of their agents or of the importers handling motor cars, and thus sometimes grant more than 90 days for the settlement of their accounts.

"However, in many cities the customs are now crowded with high-priced cars which have not been taken out by the consignees. As the storage charges amount to 1 per cent. of the invoice for the first month, 2 per cent. the second month, 4 per cent. the third month, and thus keep on an ascending scale the price to be paid for the cars when the consignee is finally in a position to take them out is generally so high that the cars are left with the customs and thus annually a large number of high-priced automobiles have to be sold by the government, or rather by the customs, and generally the prices obtained are not higher than what a medium-priced new car costs.

Government Sold Cars

"Last May there were 300 such imported cars in the customs house at Buenos Ayres, Argentine, and I know of two instances where $5,000 cars were offered for $2,000 and it was not at all an easy matter to find purchasers, notwithstanding their real value.

"The majority of automobiles owned in South America are bought by the wealthy city people who are able to afford a chauffeur. The number of owner-drivers is very small, but with the advent of the moderate-priced American cars it is very likely that the number will be increasing more rapidly. The owner-drivers are especially to be found in certain sections of Brazil.

Farmers Will Buy

"The number of farmers owning automobiles is still relatively small, but during the last 18 months the number has increased and is certain to go on increasing, as the dealers are directing their efforts much more than heretofore to the agricultural sections of the country, such as the provinces in Brazil where coffee is grown.

"The greatest drawback for the more rapid progress of the automobile business in most all of the South American countries is the entire lack of good roads, for outside of the highways and roads near the big cities there are hardly any roadways at all. Even in Africa one will find better highways than in South American countries. As an example of this, I will cite the case of a party of motorists which made a trip from Rio de Janeiro to Sao Paulo, a distance of about 400 miles—about as far as from New York to Buffalo—and it required 13 days to make the trip.

Argentina Needs Stone Roads

"In Argentina there is now a big movement afoot for having good roads built, as the recent extraordinary season of rain—it rained practically continually during the months of March, April and May—made the highways and roads absolutely impassable. As a consequence 30 per cent. of the corn crop was absolutely lost as it was impossible to haul it to the railroads. This could not have happened if stone or macadam roads had existed.

"Under ordinary weather conditions it requires about 10 hours to drive from Valparaiso to Santiago, in Chili, the distance being some 100 miles, but part of the year, during the rainy season, the roads are impassable and motor car traffic impossible.

"In some of the South American countries the application or the levying of duty by the customs is somewhat of an unpleasant joke, as there is a great difference when the duty is levied in gold or when it is in paper; for instance, in Brazil there is, according to the tariff, a 7 per cent. preferential tariff on American motor cars, but as a matter of fact when it comes down to actually settling the bill the duty amounts to 18 per cent.

"One of the principal reasons why the American manufacturers have always been at a disadvantage in doing business in South America is the lack of American banks in those countries. By being compelled to send their bills of lading and other shipping documents and invoices through the foreign banks in South America, our foreign competitors are naturally able to learn, not only our prices, but also who our customers are. This is a condition which I understand is now in a fair way being relieved."

British and Italian Cars Being Imported

NEW YORK CITY, Oct. 5—Agents in this city for French, German and Belgian makes of automobiles are receiving no shipments from the other side. Dealers in English makes are able to obtain a few cars and have not been as yet seriously injured by the war. The firms dealing in Italian cars, however, are in an enviable position, as the Italian government has given permission for the exportation of pleasure cars of 30 horsepower and less.

The Fiat Motor Sales Co., in particular is enjoying the benefits of Italy's neutrality. E. R. Hollander, president of the company, states:

"Our factory has shipped us more than 180 cars since war was declared. Some of these we have received, some are in the Custom House and some are afloat. There are available for our use forty-five more automobiles which the factory had made up at the time war was declared.

"As automobiles are contraband of war, our factory was unable to sell any of the stock on hand to any of the warring nations after hostilities opened, and so the automobiles were shipped to America. The government, which seems to be expecting war, has placed an embargo against the exportation of commercial motor vehicles."

E. L. Dugas of Lancia & Co., stated that several Lancia machines are in the Custom House and that another shipment is expected from Italy on October 6. He states:

"The only restriction that the Italian government has placed on our factory is that it export cars only to neutral countries."

The Peugeot Auto Import Co. is relying for its future supply upon the factory branch in London. It has several models on its salesroom floor at present.

R. W. Schuette, American agent of the Rolls-Royce, states that he expects in the next few months to handle about fifty cars, or one-sixth of the entire annual output of the British factory. He has received about a dozen chassis and there are a number now on the way.

Tire Prices at Before-War Level

NEW YORK CITY, Oct. 5—Not only have tire prices reached the level from which they ascended at the outbreak of the European war but one reduction has been made. The United States Tire Co. has made reductions in its chain tread casings ranging from about 4 to 15 per cent. This is a reduction from the before-the-war list, and the cut is larger on the smaller sizes. The 32 x 3 1-2 is dropped from $27.40 to $20.10 and the 36 x 4 1-2 from $49.35 to $42.

These prices went into effect and at the same time the United States returned in all other cases to its before-the-war list. When tires started downward, following their rapid ascent, United States, Goodrich and Diamond, Republic and Fisk went back to their old dealers' discounts, but kept the higher list. But inasmuch as the list is seldom adhered to by dealers anyway the maintenance of the list was considered largely theoretical.

October 1, when the United States returned to the old list, Goodrich and Diamond did likewise, and the day following, October 2, the Fisk Rubber Co. also went back to the old list. The Republic Rubber Co. is still at the higher list, but its dealers' prices are normal.

Crude Rubber Still Cheaper

Prices of rubber continue to decline, owing to lack of buyers. It is also suggested by the *India Rubber World* that an expected loss of interest in high-class rubber goods is affecting the market.

Para was selling up to 63-65 cents a pound on September 30, which compares with 75-80 a month ago and 80-82 a year ago. The best grade plantation was quoted at 63-64 on September 30, 75-80 on September 1 and 60-61 on October 1.

N. Y. Gets $1,462,968.86 in License Fees

NEW YORK CITY, Oct. 4—Mitchell May, Secretary of State, reports up to September 2, motorists have paid in to the state in fees for the registration of motor vehicles and chauffeurs' licenses a total of $1,462,968.86, which is nearly $200,000 in excess of the amount contributed for the same purpose during the whole of last year. So far there have been registered 161,353 motor vehicles. This is an increase of 36,090 over the corresponding period of last year. The number of chauffeurs licensed is 61,398. During all of last year there was registered only 132,450 motor vehicles and 56,702 chauffeurs.

The New York City bureau continues to hold a big lead both in the number of licenses and registrations issued. To September 8 this year the cars registered in this city were 71,407, as against 59,667 in the same period of 1913. The increase in the number of chauffeurs was more than 4,000.

The Buffalo bureau stands second, considerably ahead of Albany. To September 8, Buffalo shows 49,879 cars registered, increase over the same period of last year of more than 12,000. The Albany registrations total 38,353, an increase of a little more than 10,000.

Minneapolis Industry Employs 1,437

MINNEAPOLIS, MINN., Oct. 5—Industrial survey by a division of the Minneapolis Civic and Commerce Assn. shows there are six automobile manufacturing plants in Minneapolis 88 distinct motor car repair shops, 11 distinct accessory manufacturers; also, 24 gasoline filling stations outside of Bowser tanks at garages and drug stores. The employee list is a total of 1,437, of which 384 are in the factories, 863 in the repair shops, and 119 in the accessory plants. In the filling station work 71 men are employed. In addition six plants build electric batteries, employing 57 men.

The manufacturers of cars are the H. E. Wilcox Motor Co., trucks; Ford Motor Co., general; Nott Fire Engine Co., motor-propelled fire apparatus and motor pumping engines; Dispatch Motor Car Co., pleasure cars; Robinson Motor Truck Co., trucks; Braise Motor Car Co., trucks and cyclecars.

Market Reports for the Week

Market prices this week were a little unsettled. All changes but one were lower. Tin experienced a fluctuating week. Opening at $30.90 and rising to $31.13 on Thursday, it closed with no change for the week. There was small response from copper customers, though both electrolytic and Lake were offered at reduced prices. Antimony rose to $0.10 at a gain of $0.01 1-2. There was an inquiry for 300 tons for Europe on Tuesday, causing sharp buying by the dealers here. Little buying for foreign account, however, was done for these prices are above those at London. Rubber prices were steady, especially Up-River Para, which was quoted at $0.65. Cottonseed oil saw a gradual decrease from $5.85 a barrel to $5.53, with trading a little more active at the end of the week. The petroleum market was steady with no changes. Linseed oil dropped to $0.53 on Friday at a loss of $0.03. Lard oil dropped to $0.92, or 1 cent lower than the opening price. Cyanide potash dropped from $0.32 to $0.28.

C. of C. Has Record Show Applications

NEW YORK CITY, Oct. 7—Feeling that in the elimination of the proposed tax on automobiles against manufacturers and dealers, the Finance Committee of the Senate at Washington has properly recognized the position of the motor car industry, there was a general sentiment of appreciation at the meeting of the Directors of the National Automobile Chamber of Commerce held today at the New York headquarters.

Representatives of the Chamber visited Washington and supplied facts regarding the making and marketing of automobiles and those facts, coupled with protests from thousands of dealers and manufacturers of automobiles, parts and accessories throughout the country, it is believed, showed clearly to the lawmakers at Washington how unfair it would have been to require the automobile industry to carry such a heavy burden as the tax would involve.

While it is true that a number of the larger concerns have been very successful in the marketing of cars, it was felt that the industry should not be judged solely by the great successes of eight or ten makers, when there are 450 listed manufacturers of automobiles in the country and more than 15,500 dealers, besides 13,630 garages and the hundreds of factories making parts and accessories.

At to-day's meeting the component vehicle warranty clause was adopted and there were reports from committees on patents, traffic, commercial vehicle, good roads and shows.

While the automobile industry has suffered with other lines by the depression in trade and by the practical elimination of its export business, which last year amounted to $34,500,000, further proof that the automobile is a necessity in various lines of business and for doctors, contractors, salesmen and other business men, was furnished by the traffic department reports which showed that shipments in substantial quantities were made by practically all factories during August and September.

The Show Committee reported a record number of applications of space at the National Automobile Shows at New York and Chicago, the drawings for which will take place tomorrow in connection with the semi-annual meeting of members.

President Charles Clifton presided and the others in attendance included: S. T. Davis, Jr. (Locomobile); Roy D. Chapin and Howard E. Coffin (Hudson); C. C. Hanch (Marmon); H. H. Rice (Waverley); S. D. Waldon (Packard); Wilfred C. Leland (Cadillac); John N. Willys (Overland); H. O. Smith (Premier); E. R. Benson and A. R. Erskine (Studebaker); Wm. E. Metzger (American Electric) and Alfred Reeves, General Manager.

Studebaker's September Sales, $4,277,797

DETROIT, MICH., Oct. 3—The total value of the Studebaker cars sold by the thirteen Studebaker branches in the United States during the month of September was $4,277,797.92, which is the best September business the Studebaker Corp. has ever had.

The totals for each branch in dollars are not given but the percentage of increase over the corresponding month in 1913 and the showing is rather exceptionally good for several cities, while the total average gain for the thirteen branches is 232 per cent.

Gain in sales for each branch in September, 1914, according to percentage over September, 1913:

Omaha, Neb.	520 per cent.	Boston, Mass.	222 per cent.
Kansas City, Mo.	508 " "	Detroit, Mich.	114 " "
Chicago, Ill.	322 " "	San Francisco, Cal.	107 " "
Minneapolis, Minn.	270 " "	New York, N. Y.	77 " "
Dallas, Tex.	268 " "	Los Angeles, Cal.	71 " "
Philadelphia, Pa.	251 " "	St. Louis, Mo.	49 " "
Atlanta, Ga.	245 " "		

$50,000 of Michigan Buggy Claims Cancelled

KALAMAZOO, MICH., Oct. 5—In the matter of the Michigan Buggy Co., bankrupt, contested claims amounting to approximately $50,000 have been disallowed by Referee in Bankruptcy Banyon of Benton Harbor. The decision was made at a hearing held here.

The claims disallowed were presented by William R. Beebe, A. H. Vayo Co., Lewis Spring & Axle Co., Herbert Mfg. Co., Ernest F. Briggs, Michigan Motor Car Co., Journal Co., George F. Thompson

& Sons Buggy Co., Lewis Engelhausen, R. Kloeppel, E. F. Gerber, Owenhouse Hardware Co., H. Jacoby, F. F. Taylor & Son, C. J. Stone, J. T. Coleman, Hubbard & Hubbard, M. D. Harris, John L. Bridges & Son, A. P. Spell, Scott & Tiffany, E. Vander-Carr and Carr Auto Co. Claims allowed at the same hearing were as follows: Mayo Radiator Co., $308; F. G. Wood, $136.02; G. S. Patterson, $790.18; Reed Foundry & Machine Co., $2,500; Cecil White, $1,900; John Hamilton, $436; R. L. Carmell, $1.01; Slater & Co., $36.70; LaCross Motor Co., $8.80; B. H. Adams, $1.50; G. E. Meyers, $1.16; J. M. Nash, $74.31; H. B. Shirk, $66.63.

Walpole Tire Co. Earned $30,000 in August

BOSTON, MASS., Oct. 3—There were sixty present at the meeting of the Walpole Tire & Rubber stockholders. Judge Harris, one of the receivers, in the course of outlining general conditions with the company stated that there are about 800 stockholders, of whom 241 are women. He stated that the Walpole company earned $30,000 in August and for no month less than $20,000 since the receiver took charge. In 6 months $160,000 was paid off to creditors.

Auditor Keith stated that from January 31 to June 30 of this year the company earned $125,000 and that with one exception all the departments were now on good-paying basis. The good-will item has been marked down from $800,000 to $250,000. $422,000 has been paid out since the receivership, including $60,000 to the Traders Bank. Counsel Metzler stated that including the subsidiary company profits, average earnings had been $30,000 a month. The indebtedness of $1,100,000 has been reduced to $250,000. The company has about $750,000 quick assets.

Swinehart Co. Has $137,000 Surplus

AKRON, O., Oct. 3—The directors of the Swinehart Tire & Rubber Co. met September 30 and declared the usual dividend of 6 per cent. on the common stock of the corporation. The report to the stockholders showed a very prosperous year ending August 30. After paying all charges and dividends and charging off a large sum for depreciation, there remains a surplus of $137,000. The plants of the company are running at almost 80 per cent. of capacity and the future outlook is excellent.

Missouri Fair Crowds Inspect 18 Cars

SEDALIA, MO., Oct. 3—Eighteen different makers of cars were shown in the motor show at the Missouri State Fair, which closed here Saturday. The exhibits were mostly by Kansas City dealers and reports are that the fair business was exceptionally good.

The car salesmen here explained that Missouri is unusually prosperous this year. A huge corn crop is in the making and the wheat yield was one of the best in the history of the state. With the exception of a few districts in central eastern Missouri, the recent dry weather caused little harm to the growing crops.

That Missouri is rapidly becoming a motor state was shown by the attendance. On big Thursday of the fair more than 2,000 cars were parked in the grounds. Practically all of these toured to Sedalia from points as far distant as 100 miles.

U. S. Rubber Co. Has $8,000,000 Cash

NEW YORK CITY, Oct. 6—President Colt, in commenting upon the action of the United States Rubber Co. directors in declaring the regular quarterly dividends on the preferred and common stocks, said: "Dividends having been amply earned and the finances of the company being in an easy condition, with $8,000,000 cash on hand, I think the action of the board is not only conservative, but one that is entitled to commendation in these times. The division of $1,700,000 at this time among 15,000 stockholders will, I am satisfied, do much good."

PITTSBURGH, PA., Oct. 3—A dividend of 1 3-4 per cent. on the preferred stock and 1 per cent. on the common stock has been declared by the Westinghouse Electric Co., payable October 15 on the preferred and October 30 on the common.

Motion for U. S. L. Sale Denied

BUFFALO, N. Y., October 7—Judge Hazel, in the Federal Court, denied the application of Alfred Stickney, representing the Central Trust Co., for an order authorizing the sale of the United States Light & Heating Co. The Stockholders and Protective Committee and merchandise creditors were authorized to intervene. James O'Moore, one of the receivers, and Louis Posner, attorney for the company, opposed the motion, claiming that the company would soon be in good financial standing.

WASHINGTON, D. C., Oct. 1—A drawback allowance was today granted by the Treasury Dept. on the exportation of automobile tops manufactured by the American Top Co., Jackson, Mich., for the use of imported mohair cloth, imitation mohair cloth, jute webbing, buckram and celluloid sheets.

An allowance was also given on aluminum automobile hoods manufactured by the Michigan Stamping Co., Detroit, Mich., with the use of imported sheet aluminum, for the account of the Ford Motor Co., that city.

NEW YORK CITY, Oct. 4—The United States Rubber Co. declared the regular quarterly dividends of 1 1-2 per cent. on the common, 2 per cent. on the first preferred and 1 1-2 per cent. on the second preferred stock, payable October 31, to stock of record October 15.

Defunct Hoosier Bus Line Pays Stock Dividend

INDIANAPOLIS, IND., Oct. 3—J. I. Gardner, receiver for the Rapid Transit Motor Co., has been authorized by the court to pay a dividend of 2 1-2 per cent. to stockholders and it is understood another dividend may be paid later. All creditors have been paid in full. The company formerly conducted a motor bus service in Indianapolis, but the venture did not prove successful.

NEW YORK CITY, Oct. 7—C. Arthur Benjamin, has been made sales manager for the George W. Houk Co., Buffalo, N. Y. He was formerly general manager of the Fiat company at Poughkeepsie, N. Y.

August Exports Feel War Shock—Drop to $762,422

WASHINGTON, D. C., Oct. 6—Automobile exports from this country for the month of August have fallen off $1,676,208, compared with the same period in 1913, or from $2,438,630 to $762,422. This amounts to about 60 per cent. Tire exports dropped from $377,031 to $188,002, or about 50 per cent.

For the 8 months ending August exports dropped $2,218,-278, or from $23,710,140 last year to $21,491,862 this year.

Figures issued by the Bureau of Statistics show the exportation during August, 1914, of 66 commercial cars valued at $124,016, 385 pleasure cars valued at $441,879 and parts valued at $196,527. In the same month last year these exports were as follows: Commercial cars, 68, valued at $109,-437; pleasure cars, 1,936, valued at $1,874,312, and parts valued at $454,881.

During the eight months ending August exports of commercial cars amounted to 509, valued at $772,257, while the pleasure cars numbered at 18,884, valued at $16,612,060, and the parts $4,107,545. During the same period in 1913 the figures were as follows: Commercial cars, 730, valued at $1,260,-086; pleasure cars, 18,464, valued at $18,484,396, and parts $3,985,658.

EXPORTS—	August, 1914 NO.	August, 1914 VALUE.	August, 1913 NO.	August, 1913 VALUE.

Detroit May Have Most Perfect Traffic System

DETROIT, MICH., Oct. 3—Working in co-operation, the Detroit Board of Commerce, the Wolverine Automobile Club, the Detroit Police department and many prominent citizens have started a movement, a campaign which is to result in providing this city with the most perfect traffic system.

Frederick H. Elliott, secretary of the Safety First Society of New York was the principal speaker at a meeting held at the Board of Commerce and he told of what had been accomplished in New York. He urged the formation here of a similar society and this was decided upon, by president C. B. Warren of the chamber who will appoint a special committee to prepare a plan of action.

Among the various suggestions offered by the different speakers these are the most interesting: Licensing of all drivers of automobiles; authorization given to the city and state officials for the revocation of the drivers' licenses in case of carelessness and negligence having caused accidents; severe penalties for drivers having caused accidents while under the influence of liquor; more rigid examination of applicants for a driver's license as to their body fitness, that is to say good health; the passing of an ordinance prohibiting pedestrians to cross streets in the congested districts except within the specially marked "cross" sections reserved to pedestrians; all vehicles to be compelled to have tail-lights; prohibition of glaring head-lights; prohibition for fire engines, ambulances and other vehicles not required to observe the speed regulations when going to a fire or hospital to observe them when returning from such calls; teaching to the school children how to walk and cross the streets; display of accidents at moving picture shows and theaters, showing how accidents happen, how they can be avoided.

The suggestion of Alderman Lodge, who will introduce an ordinance at the next meeting of the common council to provide for the construction of elevated safety zones at street car stopping places, is meeting with great favor. It is contended that such elevated stopping places located at the places where at present the white safety zone lines are marked on the level street, will improve conditions to a great extent. It is suggested that these raised platforms be constructed of concrete and that they be provided with lights at both ends.

Trego Is Assistant Manager of Knox

DETROIT, MICH., Oct. 3—Frank H. Trego, who since September 1912 has been connected with the research engineering department of the Packard Motor Car Co., has become assistant general manager of the Knox Motors Co., Springfield, Mass., assuming this post on October 1. Mr. Trego has had a long connection with the automobile industry, his factory experience dating from 1909 when he was one of the engineers with the Hudson company when its Model 20 was placed on the market. After this Mr. Trego became chief engineer of the Thomas Motor Car Co., Buffalo, and 2 years ago installed the department of research in the engineering department of the Packard company. During the last 2 years his efforts have been spent in the development of the present Packard motors.

Mr. Trego has approached the engineering problem from somewhat a different angle than many engineers, his efforts combining much practical work with theoretical and research endeavor. His policy has been one of working cars out at great length on the road and subjecting them to all kinds of hardships rather than spending all his time in the drafting room and the laboratory. It is not surprising that, because of following out this program, he has been successful in giving cars of special performance and free from many of the annoying difficulties that often follow cars developed entirely in the laboratory.

The Packard company tendered Mr. Trego a complimentary dinner before leaving.

Asks Receivership to Prevent Marion Sale

INDIANAPOLIS, IND., Oct. 6—Suit asking $4,000 judgment, the appointment of a receiver and an order restraining the company from turning its assets over to J. I. Handley, has been filed in the Superior Court in Indianapolis against the Marion Motor Car Co. by the Standard Brass Foundry. A hearing will be held October 12, pending which time the company has agreed to not dispose of its assets. It is alleged the company has accepted a bid of $71,375 from Handley for the assets and that last December the company made an agreement with its creditors under which indebtedness was to be extended, payments to be made in installments. In October, 1913, James E. Kepperley was appointed receiver for the Marion Motor Car Co. and was discharged January 24, 1914.

$2,700 for Hudson Landau-Limousine

DETROIT, MICH., Oct. 5—A landau-limousine is the latest addition to the line of Hudson cars made by the Hudson Motor Car Co. This new style body is built on a Hudson six-40 chassis and sells at $2,700. It combines luxury and the very latest improvements to make traveling in closed cars as comfortable as possible. This landaulet presents all the comforts of a standard limousine and the movable top may be dropped to give practically all the advantages of an open car. The top is of solid aluminum with perfect fitting waterproof joints to prevent the possibility of a leak. Leather is only used in a portion of the back quarter.

A Delaware Gasoline-Electric Truck

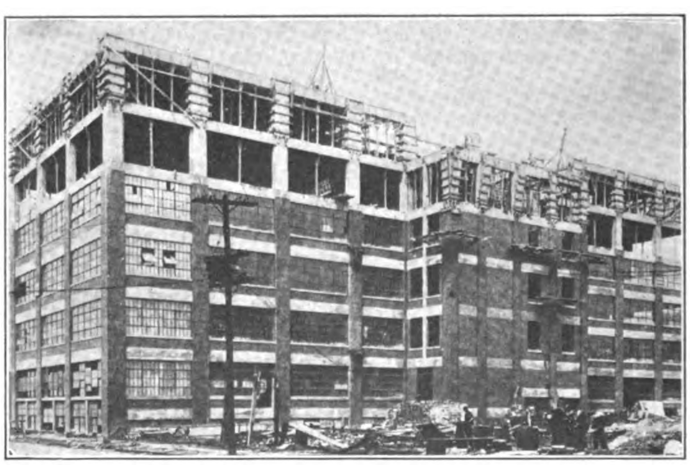
WILMINGTON, DEL., Oct. 5—The Standard Arms Mfg. Co., which is located here, has begun the manufacture of motor vehicles, and under sub-contract with the Field Omnibus Co., has just delivered a twenty-eight-passenger motor bus to the Springfield Transit Co., of Springfield, Mass. Power is furnished by a gasoline engine, with electric generator set, electric motors driving the wheels. This is the second machine the company has turned out.

Detroiter Now $985—Rebate to Buyers

DETROIT, MICH., Oct. 5—Since the first day of this month the price of the Detroiter cars has been reduced from $1,050 to $985. All purchasers of 1915 cars since August 1 are requested to call at the dealer or distributer from whom they purchased their car and they will be given a cash rebate of $65. This price reduction was expected by the dealers, inasmuch as at the annual convention held in July President C. S. Briggs of the Briggs Detroiter Co. stated that the price of the 1915 model would be reduced as soon as the production had reached twice the rate of cars made during a specified number of months in 1913.

No Separate Truck Show in Boston

BOSTON, MASS., Oct. 3—There will be no separate motor truck show in Boston next March, but a combined passenger car and commercial vehicle exhibition at the one time in Mechanic's building. This was the result of the annual fall meeting of the Boston Automobile Dealers' Assn. and the Boston Commercial Vehicle Dealers' Assn. held this week. The matter was given careful consideration and the members of the latter organization felt that a separate show would be unwise, and they agreed to accept space in the basement of Mechanic's building for their trucks and delivery wagons. Much of the space for passenger cars has already been spoken for by the Boston dealers, and there are new applicants



New factory of Hyatt Roller Bearing Co., Newark, N. J., to provide for the increased demands for its product. The new structure is 75 by 200 feet and will comprise six stories and a basement. The building is of cement and steel construction, conforming with the general plan of the others in the group. The work now has reached the top story and the machinery already is being placed on the lower floors coming in every day. Manager Chester I. Campbell of the show states that he will be able to combine the truck and passenger car shows without any great trouble. It will not be possible to have such a big truck show as formerly, but it will be big enough to make it a feature. E. A. Gilmore resigned as a director of the commercial association and Frank Crockett of the Knox was elected to fill the vacancy.

Mitchell Averages 15.5 M.P.G. for 1,946 Miles

NEW YORK CITY, Oct. 6—The Mitchell 35-horsepower light four car, which left Chicago September 23, in an effort to cover 250 miles a day with its bonnet sealed, arrived in this city on September 30, after covering 1,946 miles in 170 hours and 5 minutes. The car averaged 15.5 miles to the gallon of gasoline and 300 miles to the quart of oil.

The car left for Philadelphia, Baltimore, Washington, Wheeling and then back to Pittsburgh, the purpose being to drive the car with sealed bonnet 7,500 miles, the average mileage made in a year by an owner.

National to Continue Four-Cylinder

INDIANAPOLIS, IND., Oct. 5—To meet the demands of those desiring a four-cylinder car, the National Motor Vehicle Co., Indianapolis, Ind., will continue their series V-3 during the coming season. It was stated in THE AUTOMOBILE for September 24 that a six only would be marketed. The motor dimensions of the six are 3.75 by 5.5 and it sells for $2,375 and $150 extra with wire wheels.

Klaxon Reorganizes Sales Organization

NEWARK, N. J., Oct. 6—The selling organization of the Lovell-McConnell Mfg. Co. has been reorganized and enlarged. The sales and advertising departments have been merged into one. Additional territorial managers have been appointed.

The new selling organization will direct both sales and advertising and will be in charge of a committee composed of W. O. Turner, secretary of the company; C. L. Mead, Advertising Manager, and C. F. Brown. F. M. Hayes, who formerly represented the Klaxon in the West and in New England, will continue in charge of the New England territory. R. G. Coghlan has been transferred from the Mississippi territory to take charge of the Eastern territory, which includes New York, New Jersey, Pennsylvania, Delaware, Maryland and the District of Columbia.

W. J. Whaley, who formerly had charge of the sales for the Atlanta branch of the Western Electric Co., has been given the Southeastern territory. This includes Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Tennessee.

Charles Johnson, who for the last 3 years has acted as outside representative of the president, is now manager of the newly established Detroit office in the Dime Bank Building of that city. Mr. Johnson has charge of the factory business in Detroit, Toledo and Michigan cities, and of the sales in Michigan and eastern Canada. He will also supervise the work of the new permanent service station which has been established in Detroit at 108-114 Jefferson avenue and which is in charge of W. G. Packard.

R. L. Wilkinson continues in charge of the Middle Western territory with headquarters in Chicago. This territory includes the states of Wisconsin, Illinois, Indiana, Ohio, West Virginia and Kentucky.

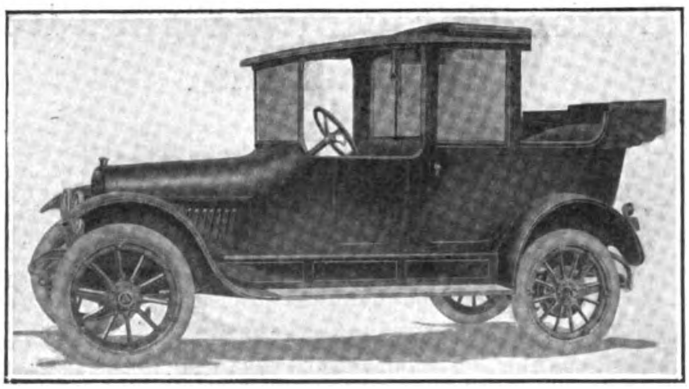
The Mississippi territory has been divided. W. P. Coghlan, late sales manager of the Moon Motor Car Co. of New York, has been placed in charge of the northern division, which will henceforward be known as the Northwestern territory. This includes the states of Minnesota, Iowa, North Dakota, South Dakota, Nebraska, Wyoming, Montana and Missouri, except Kansas City.

Arthur E. Francis, formerly of the Champion Spark Plug Co., Toledo, has been assigned to the Southwestern territory. This includes the city of Kansas City, Mo., and the states of Arkansas, Kansas, Oklahoma, Texas, New Mexico, Colorado and Utah.

The Pacific Coast territory, including western Canada, will be in charge of W. R. Johnston, formerly assistant general manager of the Stromberg Motor Devices Co. of Chicago, and for the past 3 years Pacific coast manager for the Stewart-Warner Speedometer Corp.

New Rayfield Averages 24.2 M.P.G.

CHICAGO, ILL., Oct. 3—Under the supervision of F. E. Edwards, chairman of the technical committee of the Chicago Automobile Club, the Findeisen & Kropf Mfg. Co., of this city, manufacturer of the Rayfield carbureter, held a test last Thursday that brought out officially the merits of the model G Rayfield carbureter in the way of economy, accelera-



New Hudson landau-limousine which sells for $2,700 mounted on the six-40 chassis

tion, low throttling, speed and hill-climbing without any change in adjustment.

The car used was a 1915 model 80 Overland, four-cylinder, 4 1-8 by 4 1-2, and weighing 3,620 pounds, carrying four persons. Charles Merz, former race driver, was the pilot, and besides Mr. Edwards the car carried S. D. Hirschl, chairman of the technical committee of the Chicago Motor Club, and E. A. Rossow, manager of the Chicago Rayfield branch.

On 1 gallon of 58 Standard Oil gasoline the car ran 24.2 miles. In the way of acceleration a speed of 30 miles an hour from a standing start was attained in 12 1-5 seconds. Then the Overland throttled to 3 miles an hour on high and quickly accelerated to 42 miles per hour. On Hubbard's hill, about the only grade about Chicago suitable for such tests, the Overland went from a standing start to a speed of 18 miles per hour on high at the top. The next hill trial was from a flying start and the speed of 12 miles per hour at the bottom was increased to 18 at the top.

Findlay Men Rehabilitate Adams Truck Co.

FINDLAY, O., Oct. 5—Through the efforts of the Findlay Business Men's Assn. the Adams Bros. Truck Co., of this city, will be reorganized and remain in Findlay. W. D. McCaughey is the receiver now. The business men's association raised $12,500 in new subscriptions, and Murry Irwin, of the Louis Spring & Axle Co., Jackson, Mich., will take a like amount of stock and probably become the general manager. It is the plan to settle with creditors at 20 cents on the dollar, or 40 cents in stock, rather than have the company go through an expensive receivership. The entire matter will probably be closed up this week.

Receiver Named for Crescent Motor Co.

CINCINNATI, O., Oct. 2—L. J. Howe of this city has been appointed receiver of the Crescent Motor Car Co. in the United States District Court as the result of the filing of an involuntary bankruptcy petition against the company by its creditors. This company is successor to the Ohio Motor Car Co.

NEW YORK CITY, Oct. 6—The Motor Contest Dealers' Assn. will hold its first dinner at Healey's restaurant on the evening of October 17.

Howland Addresses Electric Vehicle Assn.

NEW YORK CITY, Sept. 30—Ellis L. Howland, secretary of the Motor Truck Club of America, spoke to-night on the subject of "Practical Ideals in Electric Vehicle Promotion" before the Electric Vehicle Association of America at its monthly meeting.

Mr. Howland claimed that the criterion for judging motor trucks should be efficiency first and economy of operation second, rather than judging on a dollar cost basis in which it is often impossible to get actual horse costs.

DETROIT, MICH., Oct. 5—F. R. Bump, who has been connected with the bicycle business and later with the automobile business from the time the first automobiles were made in the United States, has joined the Studebaker Corp. and will shortly have charge of an important department of the firm.

CHICOPEE FALLS, MASS., Oct. 5—G. W. Kerr, for a number of years body engineer of the Stevens-Duryea Co., Chicopee Falls, Mass., has announced his resignation from that concern.

Boston Garagemen Fight Fire Restrictions

BOSTON, MASS., Oct. 3—When the new garage law went into effect last Thursday it was found that there were some defects in it, and at once an effort was started to secure modifications of the law. This may be done by the Fire Hazard Commissioner who has the power to make or suspend rules and regulations. John O'Keefe of Lynn, Mass., has just been appointed to the position and the representatives of the electric vehicle associations got busy and asked for a hearing on the regulation that prohibited the use of electricity in garages to some extent. It seemed at first as if there could be no storing of electric and gasoline vehicles in any garage, and this was pointed out as a hardship to the owners of garages and the electric vehicle industry as well.

The hitch in the law came over the regulations governing electricity which would exclude charging stations in garages where gasoline vehicles were cared for. So an application was made to Commissioner O'Keefe, on behalf of the Electric Vehicle Assn. and the Electric Motor Car Club. He gave a hearing on the matter at the State House during the week which was attended by F. A. Barron, of the insurance department of the General Electric Co., Schenectady, N. Y.; W. H. Blood, Jr., of Stone & Webster Engineering Corporation, Boston; J. A. Hunnewell, Lowell Electric Light Corporation, and chairman of the New England section of the Electric Vehicle Association of America; W. E. Russell, C. M. Greene, A. H. Abbott, of the General Electric Co.; T. J. Pace, Westinghouse Electric Co. of Pittsburgh; C. H. Miles, Boston Edison Co.; I. Osgood, Boston Board of Fire Underwriters; C. S. Lawler, of the Factory Mutual Insurance Co. and President Day Baker, of the Electric Motor Car Club of Boston.

Mr. Baker and his electric colleagues showed that so far as had been learned no garage fire ever originated from electric charging apparatus, and that with the improved new methods of installation fires would be practically impossible.

Abbott to Build Sixes Only for 1915

DETROIT, MICH., Oct. 6—The Abbott Motor Co., will manufacture only six-cylinder cars for 1915. At the present time a big six having a Continental motor 3 3-4 by 5 1-2 and a wheelbase of 130 inches is being delivered with a five- and also a seven-passenger body, the former costing $2,090 and the latter $2,190. A light six to weigh about 2,100 pounds with a 116-inch wheelbase and a motor probably 3 by 5, will be marketed early next year and the Abbott company is endeavoring to show this car for the first time at the New York show. The company contemplates manufacturing 2,500 cars for the 1915 season.

Weed Co. Granted Perpetual Injunction

NEW YORK CITY, Oct. 5—The Parsons Non-Skid Co., Ltd., and the Weed Chain Tire Grip Co. have been granted a perpetual injunction in their suit against the Leather Tire Goods Co., Inc., in which they alleged infringement of patent No. 723,299. Judge Hough handed down the final decree in the U. S. District Court for the Southern District of New York, ruling that the Leather Tire Goods Co. had infringed patent No. 723,299, covering the well-known Weed tire chain construction. The injunction prohibits the manufacture or sale of any infringing devices and in particular the Side Chain Kant Skids made by the Leather Tire Goods Co.

The decree states that the Parsons and Weed companies are to recover from the defendant all gain and profits from the manufacture and sale of infringing devices. Karl S. Dietz is made special master to determine the amount of such damages and report to the court. The defendant is ordered to submit to the court an account of its business in such infringing devices and to report from time to time to the special master. The Weed and Parsons companies are to recover costs of the suit from the defendant.

Indiana to Quash Invalid Ordinances

INDIANAPOLIS, IND., Oct. 5—Attorneys who have been conducting a quiet investigation, have found that in many municipalities throughout the state, ordinances have been enacted that conflict with the state motor law. It is expected that a series of test cases will be brought, with a view to having declared invalid many ordinances that are obnoxious.

There is a specific provision in the state law that no municipality shall enact an ordinance that conflicts with the state law. In spite of this fact numerous traffic measures have been adopted and ordinances have been passed attempting to fix speed limits lower than those permitted by the state.

The question also probably will be raised that it is unlawful to tax automobiles as personal property. The state motor law provides that aside from the annual state license, no motor car shall be subject to any other tax or license. Every city and county, however, has continued to require that motor cars be returned for taxation as personal property.

Boston Dealers Cut Employees' Insurance Rate

BOSTON, MASS., Oct. 3—The committee comprising J. H. Johnson of the Buick, J. W. Bowman of the Stevens-Duryea and Joseph Donovan of the Studebaker, representing the Boston Automobile Dealers' Assn. who were asked to try to secure a reduction in the insurance rate under the employers liability law, have been successful. The committee secured a new rate for all automobile dealers in New England at a substantial reduction from the old rate that the automobile men were paying to the insurance companies.

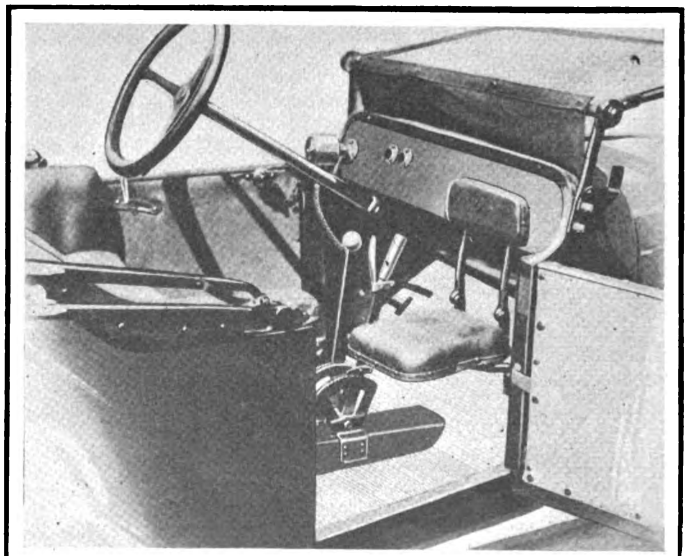
Senate to Probe Truck Purchase

WASHINGTON, D. C., Oct. 5—That the action of the Postmaster General in awarding to the White Co., of Cleveland, the contract for furnishing the Washington city post office with seven motor trucks will be the subject of a Congressional inquiry is indicated by a resolution introduced in the Senate by Senator Townsend of Michigan. Several bidders who submitted propositions have made protests against the awarding of the contract to the White Co. and have brought Congressional influence to bear to ascertain certain facts from the Postmaster General regarding the awarding of this contract. It is understood Senator Townsend is going to press his resolution and to that end is likely to deliver a strong speech in the Senate on the subject in order to force the Democrats to pass the resolution. The text of the resolution follows:

"Resolved, That the Postmaster General be, and hereby is, directed to send to the Senate at the earliest possible date all information in his possession or in the possession of the Post Office Department in any manner bearing upon the action of the department inviting the manufacturers of motor trucks, some time prior to September 8, 1914, to submit bids for supplying such trucks for the use of said department. Such information to include the department's invitation to bidders; copies or originals of the respective bids received; the action of the department in forming a committee to pass upon the bids; how, by whom appointed and under what instructions the committee acted; the full report of the committee and the reasons for its award of contract or contracts to other than the lowest responsible bidder, if such contracts were made, and all correspondence or facts that will tend to give the fullest possible information regarding this transaction."

Motor Products Co. Absorbs Cricket

DETROIT, MICH., Oct. 7—*Special Telegram*—The Motor Products Co. has absorbed the Cricket Cycle Car Co. and will continue to make the Cricket cars in two models, a pleasure and a commercial vehicle, the price to be around $300.



Saxon with folding seat for extra passenger

De Palma Thrills 40,000 at Trenton

TRENTON, N. J., Oct. 2—Ralph DePalma in his Mercedes, J. Lecain in a Chevrolet and W. D. Morton in a Mercer special were prize winners at to-day's races at the Fair Grounds here where over 40,000 people watched a program of good racing on the half-mile track. DePalma won three events and doubtless would have captured some others had the water pump on his Mercedes not gone out of commission. Lecain also was unfortunate in that when driving in the 25-mile race the axle of the Chevrolet cracked, a wheel came off, and the car struck a bale of straw which was used as a protection on the turn. Nobody was injured. C. Bergdoll, driving a Bergdoll special, was put out of the winning due to his car catching fire from the carbureter.

The summaries follow:

5 Miles, Class C, 161 to 230 Cu. In.

CAR	DRIVER	TIME
Chevrolet	J. Lecain	6:32¾
Roberts	M. Roberts	6:37
Chevrolet	G. C. Jessup	

10 Miles, Class C, 300 Cu. In. and Under

CAR	DRIVER	TIME

An Election Day Meet at Brighton

NEW YORK CITY, Oct. 6—There will be an automobile race meet on election day, November 3, at Brighton Beach. This is being promoted by O. V. Matthews.

Tetzlaff Breaks Grand Rapids Track Record

GRAND RAPIDS, MICH., Oct. 6—Teddy Tetzlaff broke the mile record for the Comstock park track here Sunday, making the mile in his Blitzen Benz in 50 seconds flat, the former record being 52 2-5 seconds. About 6,000 persons witnessed the program offered by Tetzlaff and others in the competition promoted by E. A. Moross of Indianapolis.

The summary:

3-Mile—For Local Drivers

CAR	DRIVER	TIME
Packard	White	3:29 3-5
Buick	Calrow	
Mercedes	Vandenberg	

Free-for-All—Three 3-Mile Heat

FIRST HEAT

CAR	DRIVER	TIME

New Track Records at Oklahoma Fair

OKLAHOMA CITY, OKLA., Oct. 5—Louis Disbrow, Heine Ulbricht, Johnny Raimey, T. Milton, J. Cleary and Eddie Hearne closed the entertainment features of the Oklahoma State Fair here Friday and Saturday before crowds conservatively estimated at 20,000 each day. Disbrow drove his Simplex Zip; Raimey, the Case Comet; Cleary, the Scat; Milton, the Mercer; Ulbricht, the 120-horsepower Special, and Hearne, the Case.

Two new automobile half-mile dirt track records were made Saturday. Eddie Hearne lowered Burman's record of 5:55 1-5 for 5 miles, going the distance in 5:47, and John Raimey lowered Burman's record for 3 miles from 3:32 3-5 to 3:25 2-5.

On Friday, Louis Disbrow established a new half-mile dirt track record when he drove 2 miles in 2:13 3-5 or three-fifths of a second better than the record made by him at Toledo, Ohio, last June.

One of the best exhibits at the Oklahoma State Fair this year was the automobile exhibit. The show was under the auspices of the Oklahoma City Automobile Assn. One large building, formerly used for agricultural purposes, containing 22,080 square feet, was given over to the automobile enthusiasts and more than seventy different makes of 1915 cars were exhibited.

Denver Club Back in A. A. A. Fold

DENVER, COLO., Oct. 1—After remaining out nearly a year, the Denver Motor Club has renewed its affiliation with the American Automobile Assn. The reuniting of Colorado's leading motor and good roads organization with the national body was brought about largely through the efforts of Ralph W. Smith, Colorado vice-president of the A. A. A. The club withdrew on account of dissatisfaction with the administration of the A. A. A. and the belief that this section of the country was not receiving sufficient benefits in return for the dues paid into the national organization's treasury by motorists living this far west. This action adds about 1,000 to the A. A. A. membership.

Transcontinental Run for Electric Vehicles

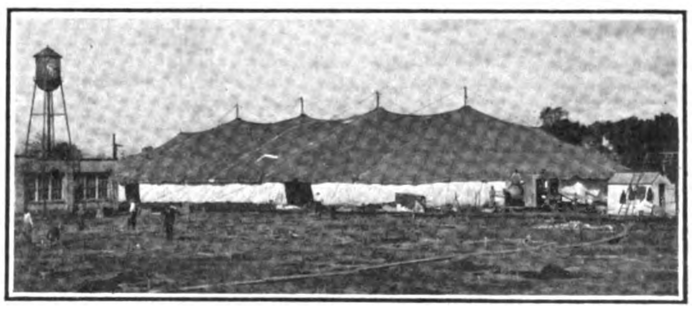
NEW YORK CITY, Oct. 7—Plans are being made by the Electric Vehicle Assn. of America for a transcontinental run over the Lincoln Highway next summer, in which both passenger and commercial electric vehicles will participate. The series of mileage tests to be held on the indoor track at Grand Central Palace, New York, during the Electrical Exposition and Motor Show which opened today have been arranged largely to furnish the mileage data needed for preparing a schedule.

The principal mileage test at the Electrical Exposition and Motor Show will be made by the General Vehicle Co., which will operate one of its 1,000-pound delivery wagons continuously during the 10-day period of the show. Two batteries will be provided and while one is in use the other will be recharged. This plan is in use by a number of companies working under high pressure.

Among the companies who will exhibit are the following concerns: Ward, General Vehicle, Anderson, Baker, Commercial Truck, Electric vehicle companies and the Gould, Edison, Philadelphia and the National Carbon storage battery companies.

Now Kalamazoo Is to Have a Speedway

KALAMAZOO, MICH., Oct. 3—It is reported that with the success of the automobile races at Kalamazoo recently, exceeding the hopes of the directors, plans are already being made for the building of a 2-mile automobile speedway together with a grandstand and bleachers that will accommodate 50,000 people. The Kalamazoo County recreation park committee met recently and decided to take up immediately the proposition. The cost of the improvements will probably exceed $200,000. It was also decided to hold the races for 2 days next year. Labor Day is to be included in the dates and a 100 mile race for a large purse with a series of other races will be scheduled.



With the constant increase in demand for its product, the Maxwell Motor Company has been forced to utilize every available building for the manufacture of its cars. The tent in the photograph was purchased by the Maxwell company for a temporary paint shop, and will be used as such until a new building can be constructed. Under this immense canvas may be seen row after row of freshly painted axle housings, six or seven hundred of them ready to be placed in the finished cars. No other part of the car is painted in the tent, other buildings being used for the purpose. In the foreground can be seen workmen making the cement bases for a spacious building which, when finished, will take the place of the tent and will be the finishing room for the factory. Enameling and painting will be done in this new building

War Golden for the German Industry

All Private Motor Vehicles Bought for Cash by Government—Factories Working Full Tilt and Overtime—Enormous Impetus for Whole Trade Confidently Expected After War Is Over

This is the translation of a letter just received—October 7—from a German subscriber for THE AUTOMOBILE who is anxious that Americans should know the exact conditions existing in the Fatherland; that is, as they existed at the date of his letter, September 2.

By Kurt Goldstein

BERLIN-CHARLOTTENBURG, Sept. 2—In receipt of your bill of July 30 I beg to inform you most cordially that it unfortunately is impossible for me at the present time to forward you the amount of $5 in payment of my subscription for the coming year, as all money remittances to America have been prohibited. I must ask you to continue nevertheless to mail me your journal as before, and you will then receive the amount of the subscription promptly as soon as the ordinary traffic is again established. I do not wish to inclose the amount in this letter, as the letter post is too unsafe and, indeed, I do not know whether it will reach you.

On this occasion I would like, however, to let you know something about the general situation here, as this certainly will interest you and possibly also your readers, especially as so much distorted information is going abroad.

Before this reaches you, the daily press will have informed you of the victories of our German army in France and in Russia. I only repeat briefly: The French are defeated over the whole line and our troops stand within 80 kilometers of the gates of Paris. The Russians were defeated by the Austrians in the battle of Krasnik, and by the German troops in the battle of Tannenberg, where alone 70,000 prisoners were taken and the entire artillery of three army corps was captured. These communications are official and therefore completely reliable. The reports of victories have stimulated all business, and I do not exaggerate when I state that here in Berlin, the capital, apart from the enormous enthusiasm for the war, no other effects of the war condition are noticeable.

From the first day of mobilization, everything was in perfect order, and there were no counter-currents against the war. The information spread abroad about socialistic mutterings and of battles lost by our German troops is purely fictitious. Further details on these points you will of course get through the daily press, as already mentioned. But I would like to let you have some facts about the automobile industry.

At the declaration of war the army administration at once requisitioned about 30,000 automobiles; even the figure of 40,000 is mentioned. Especially, every commercial vehicle, this including all the omnibuses of the local General Omnibus Co., was at once turned to military uses. They are employed by the commissariat for the transportation of food; also as ammunition wagons and in the fresh-meat service for the firing line, etc.

Over the entire country so-called Immobile Motor Vehicle Commandoes have been distributed, which have charge of the equipping of these vehicles in accordance with the rules and specifications of the army authorities. Pleasure cars were ordered to be placed at the disposal of the army on the very first day of the mobilization and most of the cars in good condition were bought. The purchase price is paid at once in cash—as in fact everything bought by the army is settled for in two to four weeks' time.

The automobile factories, especially those making trucks, work for the army administration with all the forces they can command, and these factories as well as those making parts and accessories are therefore tremendously busy. My own firm, for example, reached during the month of August the highest monthly volume of trade ever experienced. And, although a great deal of material is used, the army authorities do not by any means order anything promiscuously.

The many members of the automobile commerce who have been called to arms are also employed in the army according to their capabilities, and one finds therefore today in the motor vehicle batallion the same gentlemen who during their civilian days were most busy with automobile affairs. It is thus evident that the automobile industry will derive great benefits from this war; not only for being kept busy during the hostilities but also because most of the automobile owners whose vehicles have been bought for the army will be compelled to buy new vehicles later. On the unofficial exchange there is therefore also great demand at present for stock in the automobile manufacturing companies.

After the first reports of victories many private persons even went so far as to place orders for new vehicles at once, and those factories which at first had cancelled orders for parts have now revoked this precautionary measure.

I am quite willing, if you wish it, to send you further information, as I consider it my duty as a German to see that some veracious statements reach the press of foreign countries.

The moment Germany once again gets into regular communication with the United States you will learn the true condition of many things which are now under cover, and there will certainly then be great wonderment over the manner in which Germany went to war.

Second Used Car Report Out

CHICAGO, ILL., Oct. 6—The second issue of the Used Car Central Market Report published by the Chicago Automobile Trade Assn. has been issued. This is a 46-page issue of the report which was described in THE AUTOMOBILE, September 3, page 438, and is a comprehensive market report to tell the dealer the amount to allow in taking a used car of any year and make in trade for any machine. The information contained on the pages of this issue is strictly up-to-date, being compiled from prices obtained for used cars during the months of April, May and June. One hundred gasoline vehicles and fourteen electrics were listed in the first issue and the second has 125 gasoline and fourteen electrics. The number of sales upon which the information is based is 825 ending June 30 and the field of used cars covered is 25 per cent. larger.

Appraisal Shows $181,000 for Voiturette Co.

DETROIT, MICH., Oct. 7—*Special Telegram*—An inventory taken by the Detroit Trust Co., shows an appraised value of $181,000 for the American Voiturette Co. assets, against the company's book inventory of $444,000. The direct liabilities total $295,000 and the indirect liabilities, $213,000.

Clubs to Tour to New York Parade

NEW YORK CITY, Oct. 5—Invitations were sent yesterday to all of the automobile clubs within 400 miles of New York City to tour to New York as bodies and compete for club prizes in the Tercentenary Automobile Pageant on the night of October 28.

In addition to the list of clubs, letters have been sent by A. G. Batchelder, chairman of the executive committee of the American Automobile Association, to more than 2,600 car owners in the Metropolitan district who are members of the A. A. A.

BUFFALO, N. Y., Oct. 1—*Special Telegram*—With liabilities of $8,557.46 and assets of $2,316.41 up-to-date Auto Body and Specialty Co., Inc., of Buffalo, filed late today voluntary petition of bankruptcy here in Federal court.

CONTINENTAL Motor's Large Additions—Large additions are being made to the Detroit plant of the Continental Motor Manufacturing Co. Several new buildings have just been completed; others are under construction, and ground is just being broken for still others. Over 50,000 square feet of ground will be covered by these structures when all are finished. A new garage and steel stamping addition are already nearly ready. A wing to the heat-treating department has progressed as far as the completion of the structural steel work. This building will double this department's capacity. The largest unit of the new buildings is a continuation of the machine shop—already one of the largest structures of its kind in the world. This addition increases the floor space by thousands of square feet, wherein almost a quarter million dollars' worth of special Continental machines will be installed. The great extension to the experimental laboratories completes the additions. At the present time work on this has just begun, the foundation alone being finished. This enlarged experimental department, adding as it does over 7,000 square feet of ground space to the existing laboratories, will give the Continental company unequaled facilities for research work.

Hupp's Daily Schedule 75 Cars—Since September 28 the Hupp Motor Car Co., Detroit, Mich., has been operated on an output schedule of 75 cars daily.

Gabrielson Co. Will Build—The Gabrielson Car Parts Mfg. Co., Jamestown, N. Y., recently incorporated with a capital of $35,000, will erect a factory for the manufacture of automobile radiators.

Hyatt Acquires New Detroit Site—The Hyatt Roller Bearing Co., Detroit, Mich., has purchased a lot 165 by 161 feet on Grand boulevard and Cass avenue, where its new office building will be erected.

McQuay-Norris Opens Plant—The McQuay-Norris Mfg. Co., St. Louis, Mo., maker of the Leak Proof piston ring, opened its new factory on Locust street, in Automobile Row this week. New machinery has been installed at a cost of $25,000. The offices will take up a greater portion of the second floor together with the wholesale and out-of-town stock. The factory is on the ground floor.

White's Seattle Branch Plant—The White Co., Cleveland, O., has established a factory branch in Seattle, Wash., opening salesrooms at 1514 Third avenue, in the heart of the business district. The branch is in charge of E. W. Hill, who is in charge of the White factory interests in the Pacific Northwest, and R. G. Hubner, auditor for the White factory in this district. The Seattle branch will serve the entire States of Washington and Idaho.

Ford's New Cleveland Plant—The announcement is made by the Ford Motor Co., Detroit, Mich., to the effect that the new Cleveland, O., assembling branch, which will be erected on East 117th street, will cost in the neighborhood of $500,000. Railroad tracks will be run into the second floor of the structure and the roof will be used for testing purposes. According to H. N. Dunbar, the branch manager, the plant will be ready for occupancy early next summer.

Marathon Electric Starts Operations—The Marathon Electric Mfg. Co., Wausau, Wis., has started initial operations and is turning out a large line of electrical goods, including motors, dynamos, generators, etc., of the small type. The plant is being enlarged and a new power house erected. The company's quarters consist of the former forest products laboratory built by the Government 3 years ago and abandoned last fall at the conclusion of its pulp wood research work.

Sta-Rite Carbureter Co. in Utica—E. W. Mason, who purchased the patterns, good will, etc., of the defunct Watt Carbureter Co., Holly, Mich., is organizing a new company, which is to be located in Utica, Mich., and will manufacture the Sta-Rite carbureter. Mr. Mason is asking local stockholders of the bankrupt Watt company to take the same amount of stock they held in the old company in the new one in settlement of their claims, and it is said that most of them have accepted the proposition.

Bukolt Co. Building.—The Bukolt Mfg. Co., Stevens Point, Wis., which brought out a new device known as the Highway tire strap, is planning to erect a large factory addition late this fall or early next spring. A site 74 by 150 feet in size has been purchased and tentative plans call for a three-story structure covering nearly all of the new acreage. The concern intends to increase its capital by $50,000. Practically all of the issue has already been spoken for by Stevens Point capital.

Wants Tire Plant in Canton—Leslie Dunn, president of the York Co-operative Tire & Rubber Co., of New Orleans, wants to establish a factory in Canton, O., capable of turning out 2,000 finished tires a day. He wants to bring his shops as well as a cotton factory, where tire fabric can be made. He asks the Chamber of Commerce to give him 10 acres of land on which to erect the buildings. He also wants aid in disposing of remaining stock in the firm. His plan is unique. He would have the company include automobile owners only, each stockholder to be limited according to the number of tires he consumes.

The Automobile Calendar

Oct. 3-10	Cincinnati, O., Show.
Oct. 5-12	St. Louis, Mo., Show, Forest Park Highlands.
Oct. 7-8-9-10	Detroit, Mich., First Truck Convention of Motor Truck Manufacturers', Dealers' and Owners' Organization; promoter, Motor Truck Club of America.
Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.
Oct. 10	Medford, Mass., Track for Light Cars, Combination Park.
Oct. 10-17	Boston, Mass., New England Light Car and Cyclecar Show, Horticultural Hall.
Oct. 17	New York City, Motor Contest Dealers' Assn., First Dinner, Healy's Restaurant.
Oct. 17	Los Angeles, Cal., Show, Shrine Auditorium.
Oct. 17-23	Los Angeles, Cal., Show, Shrine Auditorium.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 17-Nov. 1	Dallas, Tex., Show, State Fair Grounds, Dallas Automobile Dealers' Assn.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn's Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 23-24	Peoria, Ill., Illinois State Assn. of Garage Owners; Semi-Annual Convention.
Oct. 28	New York City, Commercial Tercentenary Celebration.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov.	El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 8-9	El. Paso to Phoenix, Ariz., Automobile Race.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 26	Corona, Cal., Road Race, Corona Auto Assn.
Dec. 1-4	New York City, Annual Meeting of the American Society of Mechanical Engineers.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace
Jan. 3-10	Buenos-Aires, Argentina, Grand Prize of Argentina.
Jan. 9-16	Philadelphia Automobile Show.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.
Jan. 30-Feb. 6	Minneapolis, Minn., Show, National Guard Armory, Minneapolis Automobile Trade Assn.
Feb. 15-20	Omaha, Neb., Show, Auditorium, C. G. Powell.
Feb. 22	San Francisco, Cal., Vanderbilt Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Mar. 6-13	Boston, Mass., Show, Mechanics Bldg., Boston Auto Dealers Assn. Boston Commercial Motor Veh. Assn.
Mar. 7	San Francisco, Cal., Panama-Pacific Exposition, Grand Prize Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Mar. 14	San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

The Week in  the Industry

Motor Men in New Roles

BIRDSALL Heads Grossman Detroit Office—E. T. Birdsall, the well-known mechanical engineer, has been appointed manager of the Detroit office of the Emil Grossman Mfg. Co., Inc., 708 Ford Bldg., to succeed G. E. Shaw. Associated with him are F. G. Walker, M.E., and A. A. Greenburg. They will cover the manufacturing trade. A. L. Glick, who was assistant manager of the Grossman company's Detroit factory before its consolidation with the Brooklyn headquarters at the Bush Terminal, has been appointed sales representative in Michigan, Indiana and Ohio.

Martin Signal Truck Sales Manager—The Signal Motor Truck Co., Detroit, Mich., has appointed Joseph J. Martin Western sales manager.

Merritt King District Manager—R. P. Merritt has been appointed district sales manager in northwestern Ohio for the King Motor Car Co., Detroit, Mich.

Darrah Manager—W. R. Darrah has been appointed sales manager of the E. C. Johnson Co., Philadelphia, Pa., distributer of the Reo and Premier cars.

Beidler in Charge of Maxwell—H. Beidler, formerly associated with Don Lee in San Francisco, Cal., will hereafter have charge of the Maxwell interests in the Northwest, with headquarters in Seattle.

Clement Joins Bock Bearing—C. H. Clement, until recently chief engineer and sales manager of the Metal Products Co., Detroit, has resigned, and is on the road as sales engineer for the Bock Bearing Co., Toledo, O.

Castle Representing Flanders Electric—F. E. Castle has been appointed Michigan representative of the Flanders Electric Co., Inc., Detroit, Mich., and will have his headquarters and salesrooms at 872 Woodward avenue.

O'Neill Made Secretary—The Stromberg Motor Devices Co. has transferred W. L. O'Neill from the managership of its Detroit branch to the office of secretary and sales manager of the company, with headquarters at Chicago.

Van Patten in Advertising Co.—L. A. Van Patten, who recently gave up the Saxon agency, has gone into the advertising business. He has joined the Cheltenham Advertising Service, 150 Fifth avenue, New York City.

Seymour Goes to Worcester—Robert Seymour has been appointed manager of the branch of the White Motor Co., Worcester, Mass., where he will handle cars and trucks under the direction of the New England branch at Boston, Mass.

Now With the Regal—Joseph E. Burns, formerly manager of the Lee Motor Car and Supply Co., of New Bedford, Mass., and afterward with the Jackson car in Boston, has joined the Davis Automobile Co. at Providence, R. I., to sell Regal cars.

White Goes to Chicago—R. W. White, who has been manager of the Columbus, O., branch of the Goodyear Tire & Rubber Co., has been assigned to manage the Chicago branch. The new Columbus manager is W. W. Magill. The branch is located at 87 North Fourth street.

Maxwell Sales Manager to Return Home—C. F. Redden, who has been abroad for several months, has advised the Maxwell Motor Co., Detroit, Mich., that he will sail for America on the steamship "Minnehaha" October 10, arriving in New York about October 19.

Maurer Studebaker Service Engineer—E. R. Maurer, M. E., has been appointed service engineer of the Studebaker Corp., Detroit, Mich. He will have charge of all service, parts, orders and claims at the Detroit plants, and also at the various Studebaker branches throughout the country.

Hogle in Accessory Business—The Detroit Accesory Co., Detroit, Mich., has started business at 870 Woodward avenue and will handle especially Ford specialties. This is a new company organized recently by W. M. Hogle, who was formerly sales manager of the Republic Motor Truck Co.

Moore's New G. M. Appointment—President C. W. Nash, of the General Motors Co., Detroit, Mich., has appointed D. K. Moore, who is sales manager of the Weston-Mott Co., Flint, to be also sales manager of the Northway Motor Mfg. Co., Detroit, and of the Jackson-Church-Wilcox Co., Saginaw, Mich.

Griffith Promoted—H. A. Griffith, who for the past 2 years has been assistant manager of the Los Angeles branch of the United States Rubber Co., has been appointed manager of the Spokane branch, to succeed H. A. Thompson, who has been promoted to the management of the Seattle and Tacoma branches.

Judd Joins Gilmore—J. L. Judd, until recently sales manager of the Jackson Motor Car Co., Boston, has joined the E. A. Gilmore Co., representing the Lewis VI. The Gilmore company now has practically all the Eastern New England territory for the car, and Mr. Judd will tour New England, establishing new subagents.

Cappeller North East Electric Manager—Edward Cappeller has been appointed Detroit, Mich., manager of the service department of the North East Electric Co., Rochester, N. Y., which makes starting and lighting systems. The local headquarters have been opened with the Foster Motor Sales Co., 1751 Woodward avenue.

de Causse Heads Locomobile Dept.—The Locomobile Co. of America, New York City, has opened a special department for the planning and ordering of specially designed bodies. J. Frank de Causse will manage this department. He has been connected for the last 10 years with the French automobile body manufacturers, Kellner & ses Fils, as assistant manager.

Moore's New Hupp Appointment—Laurence Moore, who has devoted most of his time in promoting the foreign trade end of the business of the Saxon Motor Co., Detroit, Mich., has been appointed director of both domestic and foreign sales. Mr. Moore recently returned from an extensive business trip to Europe. C. F. Jamison, who has been sales manager, will continue in that capacity.

Poole to Return to Europe—John L. Poole, export manager of the Hupp Motor Car Co., Detroit, Mich., with headquarters in Paris, will return to Europe from Detroit in the near future for the purpose of looking into Hupmobile business. Mrs. Poole will accompany him. Mr. Poole believes that there will be business for American automobile manufacturers in Europe this autumn.

New Marmon Branch Managers—W. F. Siegmund, until recently vice-president of the Electric Garage & Service Co., St. Louis, Mo., has been appointed manager of the Kansas City, Mo., branch of the Nordyke & Marmon Co. A. B. Wagner has been appointed manager of the Indianapolis sales branch of the Nordyke & Marmon Co. He has been employed by the company for the past 6 years.

Whitehead Norwalk Tire Sales Manager—J. W. Whitehead, general sales manager of the Diamond Rubber Co., San Francisco, has resigned to join the Norwalk Tire & Rubber Co., which was recently organized in Norwalk, Conn. During eight years Whitehead was assistant to C. E. Mathewson, Pacific representative of the Diamond company, and is now general sales manager and secretary of the Norwalk company.

Bond Succeeds Root—G. A. Root, president and general manager of the Crescent Motor Car Co., St. Louis, Mo., has resigned and is succeeded by M. W. Bond of the Bond Automobile Co., retail automobile dealer in St. Louis, Mo. Mr. Bond has also acquired Mr. Root's stock in the Crescent Co. J. B. Howard has been appointed sales manager and the company is arranging to put out a small four-cylinder car listing at $985, fully equipped, including electric starter, etc.

Petre Consulting Engineer—L. J. Petre, during many years in charge of the experimental and research departments of the F. B. Stearns Co., Cleveland, O., has gone into business for himself as an expert consulting engineer, and will also organize what might be called a club, consisting of some 300 automobile owners, whose motor cars he will personally inspect at regular intervals. Mr. Petre is temporarily located with the Auto Repair, Storage & Supply Co., Euclid avenue.

Recent Champion Plug Appointments—J. T. Moultrup, well known on the Pacific Coast, and lately with John Millen & Sons, Vancouver, B. C., is now representing the Champion Spark Plug Co., Toledo, O., in the Middle West. Charles Corwin, well known to the New York trade, formerly with the Ely company and the Donnelly Motor Equipment Co., is covering the New York territory for the Champion company. E. S. Torrance, for a number of years with Post & Lester and Bi-Motor Equipment Co., Boston, Mass., is covering the Eastern territory for the company.

Accessories for the Automobilist

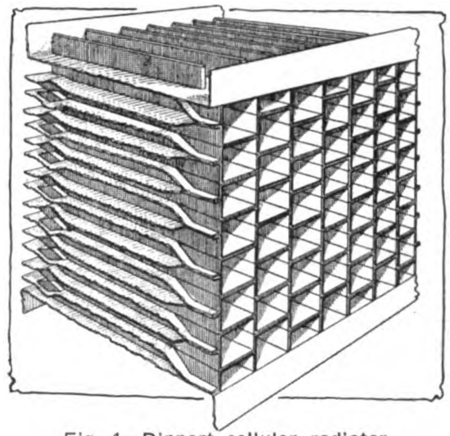


Fig. 1—Dippert cellular radiator

PULL-U-OUT Tackle — For stalled motorists, for lifting heavy loads, for all purposes where power against weight is needed, the tackle made by the Pull-U-Out Mfg. Co., 909 Pine street, St. Louis, Miss., is specially fitted, multiplying as it does the amount of force placed upon it by seventy. The mechanism of Pull-U-Out consists of a winding drum 6 inches in diameter, carrying 30 feet of quarter-inch steel tiller rope and capable of withstanding a ton pull. Internal gearing in the drum engages a bronze pinion on a long ratchet crank. A steel frame carries the drum and gearing and is provided with hook bolts and a sheave or block.

Two strong chains and three stakes of peculiar manufacture complete the outfit, which retails for $15.

Dippert Motor Radiator—A radiator of the Mercedes type is the Dippert, Fig. 1, made by the Motor Radiator Corp., Buffalo, N. Y. It is of the fin and tube type of construction but so made as to be free from the tendency of this type to leaking where the tubes enter the bottom and top headers.

Oakes Pressed Steel Pulley—To reduce weight and to make a saving in the cost of manufacture, the Oakes Pressed Steel Co. is placing for sale the Oakes pressed steel belt pulley. In the past it has been impossible to use pressed steel pulleys as there was not stock sufficient to cut a keyway. This has been overcome by brazing in a piece of tubing and cutting the keyway in the tubing. By substituting pressed steel, the weight has not only been greatly reduced, but a saving varying from 6 to 10 cents on each pulley has been made, as no machining is necessary. Being ready to assemble, a saving in time and equipment is also effected.

Halladay Automobile Bumper—Made of channel steel and designed for all styles of cars having drop front spring hangers, the L. P. Halladay Co., Streator, Ill., is advancing the Halladay bumper, (Fig. 2) as a money saver in that it reduces the chances of accident to the front of a car, thereby saving its price, $12.00, many times over by protecting lamps, fenders and radiators. In case of a severe shock the channel bar, the only bendable part, may be straightened. The other parts are practically unbreakable.

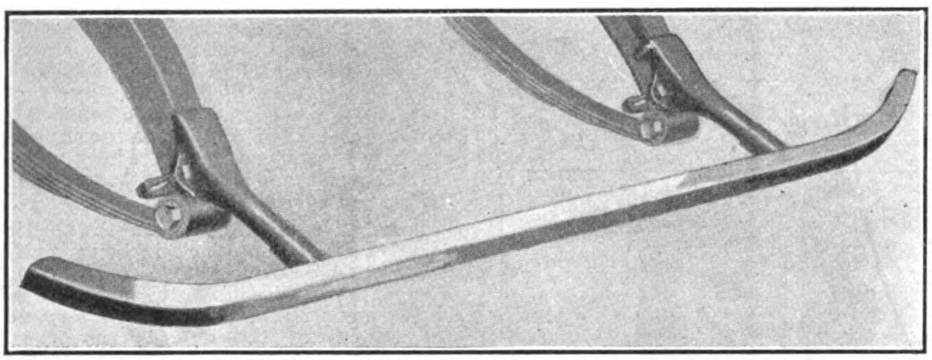

Fig. 2—Halladay steel automobile bumper

Sturges Shock Absorbers for Fords—A semi-hydraulic shock absorber, particularly adapted to Ford cars is being advanced by the Pacific Leather Works, of Oakland, Cal. It consists of a cylinder containing a spring, which is covered with oil. The springs of the car are suspended from these inner springs of the smoother, the outer arm being rigidly attached to the axle. This Sturges smoother, it is claimed, eliminates all shock and vibration.

Racine Electric Brass Polisher—To facilitate the polishing of brass-work on automobiles, the Racine Electric Co., Racine, Wis., is selling the Racine High Speed Auto Brass Polisher. This has a special high speed motor for giving the buffer the proper surface speed. The type G outfit is equipped with a 3½ by ½ grinding wheel, a steel brush wheel for cleaning tires before vulcanizing and two buffs for polishing brass or nickel plate, and has a threaded tapered spindle for attaching the various wheels. All the motors of this company are universal, operating on either alternating or direct current 25-60 cycle, 110-130 volts, with other voltages to order.

Walz Auto Signal—The improved Walz Auto Signal, Fig. 3, for indicating to other motorists which way a car will turn, or if it will stop, is simple in construction. The signal consists of two brackets, each containing two signal disks. One is situated over the number plate and the other on the left front fender. If the driver intends turing to the left, an arrow flashes in the left disks and vice versa. On stopping both appear.

Sterling Custom-made Tires—Made to order tires, with the name of the consignee stamped upon them if desired, is the offer of the Rutherford Rubber Co., Rutherford, N. J., makers of the Sterling Tires. These tires run from $8.25 for a 28 by 2½ to $53 for a 37 by 5. They are made in straight-wall and clincher quick detachable types. The Rutherford Rubber Co. is also making the Sterling Realrubber spring bumpers.

Perkins Anti-Glare Shade—Preventing the glare from the headlights of an oncoming vehicle from blinding the driver is accomplished in a simple device brought out by Perkins & Co., Grand

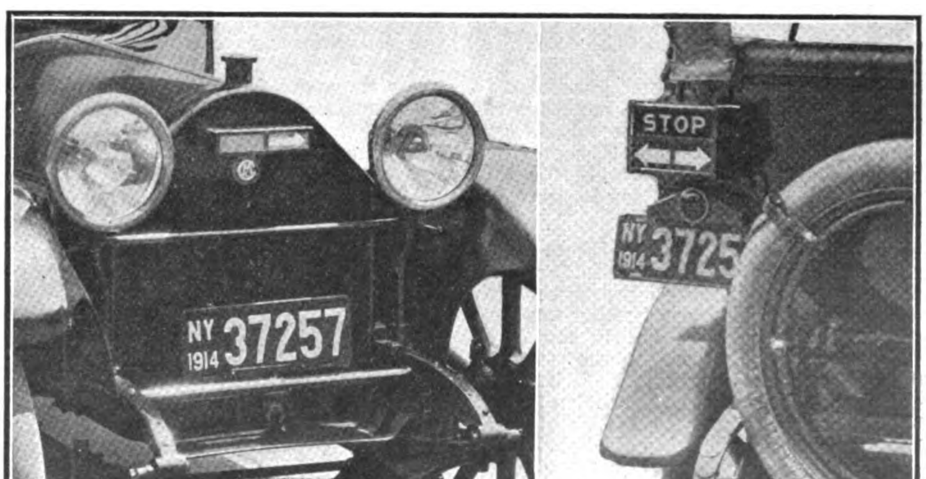

Fig. 3—Walz Auto Signal. It is attached to both front and rear

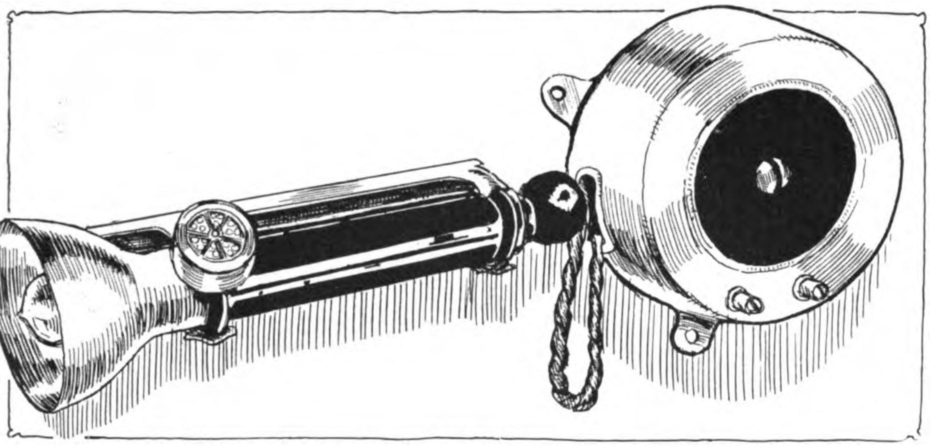

Fig. 4—Automatic cord winder attached to a combination cigar lighter and trouble lamp

Rapids, Mich., and called an anti-glare shade. It consists of a rectangular piece of amber-colored glass, properly supported on a bracket and so positioned that the driver can, by merely moving his head, cause the line of vision to go through the glass. When not needed the driver may look ahead as ordinarily but when glaring headlights appear before him he need do no more than turn his head and look through the amber glass. It is said the shade does not interfere with driving, as one may have unobstructed vision on all sides of the shade and through it without the slightest inconvenience.

Automatic Cord Winder—Fig. 4 shows the automatic cord winder manufactured by the Metal Specialties Mfg. Co., 736 W. Monroe street, Chicago, Ill., attached to a combination lamp and cigar lighter. This device holds the flexible cord running to the lamp and whenever the lamp or cigar lighter are to be used, the cord is automatically unwound, but the moment the tension is released the cord is rolled up again. The lamp fits into a simple case that may be attached to any part of the car.

The price of the automatic cord winder alone is $2.50, while combined with the cigar lighter and lamp it sells for $6. The eastern agent is Asch & Company, 1779 Broadway, New York City.

Allan's Self-Adjusting Wrench—The harder the pull the tighter the nut is held in the new wrench shown in Fig. 5 and which is manufactured by A. C. Allan, 420 West 63d street, Chicago, Ill. The operation of the wrench is simple in principle. One jaw is slotted and fitted with suitable guides, as shown, to allow the other jaw to slide in it. The handle is pivoted in the larger jaw and when force is applied moves the smaller jaw and thus grasps the nut firmly. The handle is reversible, so that it has the advantages of an ordinary S wrench. The pin that holds the handle is removable for this purpose, being held in place by a cotter pin and a washer.

New Oil-Pouring Device—When lubricating oil is poured into the motor compartments there usually is waste through sloppage over the sides of either the funnel or the can used, and it also is a difficult matter in some motors to get just the required amount of oil into the chamber. To obviate this difficulty the No-Shammy Products Co., Cleveland, O., has brought out what is called the Half-and-Half, a rectangular oil container with a spout at the bottom, the flow of oil through the spout being controllable by a thumb lever. This container, which

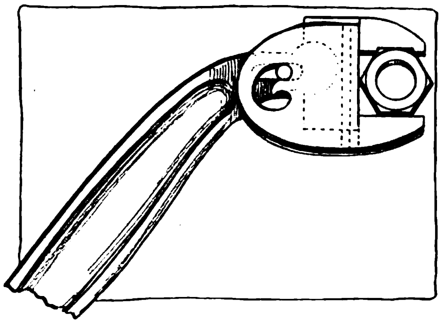

Fig. 5—Allan's self-adjusting wrench

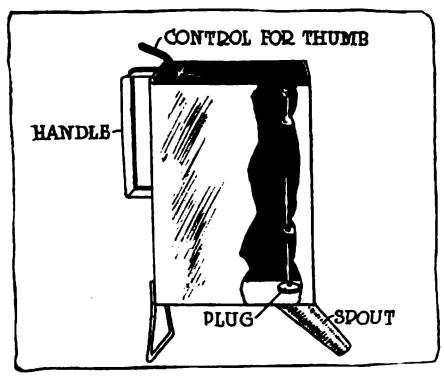

Fig. 6—No-Shammy oil-pouring can

is shown in Fig. 6, has a convenient handle, and the inside opening of the spout is covered with a small cap, which cap is connected by two rods to a thumb lever. Pressure on this lever raises the cap and thus permits oil to flow through the spout. Releasing the thumb pressure plugs the spout and stops the flow of oil. The Half-and-Half is made in two sizes, a quart size which sells for $1 and a two-quart measure which lists at $1.50.

No-Shammy Waste Can—A new idea in garage equipment, the providing of a waste can for the placing of old waste, together with a compartment for the holding of clean waste, is being sold by the No-Shammy Products Co., Cleveland, Ohio. The can is manufactured from heavy galvanized iron, and is fitted with a hinged lid at the top. It can be quickly fastened to the garage wall with wood screws. On the front is attached a sponge cup, and beneath is a swinging-rod for the drying of chamois skins. The 5-pound size sells for $3.00 and the 2-pound for $2.00.

Ogden Ratchet Swivel Joints—Claiming that breakage and distortion of speedometer shafts, gears, etc., is due largely to strains imposed upon them when the car reverses, the Ogden Fiber Gear & Tire Co., Columbus, O., has brought out a device for eliminating these faults. It is called the Ogden ratchet swivel joint, is illustrated in Fig. 7, and sells for $5. This joint is attached to the end of the speedometer flexible tubing, taking the place of the present joint, and may be used for either the left or the right side. It is fitted with gears giving the desired ratio for new or old Stewart speedometers, but the maker does not state whether it can be used with speedometers other than the Stewart. The gears used in this joint are of the spiral type.

Dahl Crescent Tube Guard—To obviate punctures, the Dahl Co., of Philadelphia, Pa., is advancing the Crescent Tube Guard, Fig. 8, a solid band made of the same material as an automobile tread, and which is tucked into the shoe, between the tread and inner tube. Great resiliency is claimed for this cushion, besides its protective qualities. Chafing and pinching are also done away with. It may be attached by anyone in a few minutes and lasts indefinitely.

Knickerbocker Luncheon Outfit—For those motorists who enjoy preparing their own meals while on a tour, the Knickerbocker Case Co., Chicago, offers a very compact case which holds sufficient food and utensils for six persons and can be carried in the tonneau back of the front seat.

It can be used as a table when extended, and then the utensil compartments are easily accessible. Many styles of this outfit are marketed, ranging in price from $15 to $75.

Beard Tire-Saving Jacks—A simple form of tire-saving jack is being marketed by the Beard Auto Lift Mfg. Co., Pleasant Lake, Ind. It is featured by a metal hook which slips around the bottom of the hub of the wheel and then by pushing down on the control the wheel is raised from the ground. When not required for use it folds up. A set of four sells for $5.

National Telescope Cylinder Pump—A tire pressure of 60 pounds may be reached in two minutes with the National Telescope Pump, which is worked by screwing it into the spark plug hole in one of the cylinders, according to the claim of the manufacturers, the National Motor Supply Co., Cleveland, Ohio. Suction from the piston of the cylinder used operates the pump, causing it to suck in and force out air as the engine revolves. This pump sells for $5.50; with a gauge for $6.50.

Paris motor buses in active service. From a photograph taken near the firing line during the battle of the Aisne between the Germans and the Allied Armies in France

French Industry Is Under War Régime

Factories Moved from Paris Brought Back Again—Skilled Workmen in Demand—Look to America for Magnetos—No 1915 French Models

By W. F. Bradley
Special Representative of THE AUTOMOBILE with the Allied Armies in France

PARIS, Oct. 1—French automobile manufacturers are still limited to one customer—the Government. The factories having commercial vehicle sections and those making aeroplane motors are working at high pressure under military control. Such remarkably good service has been obtained from the automobile lorries connected with the Army Service Corps that the authorities are doing everything possible to increase the number of vehicles. It is attempted to make up the wastage of horses by more trucks instead of by more horses.

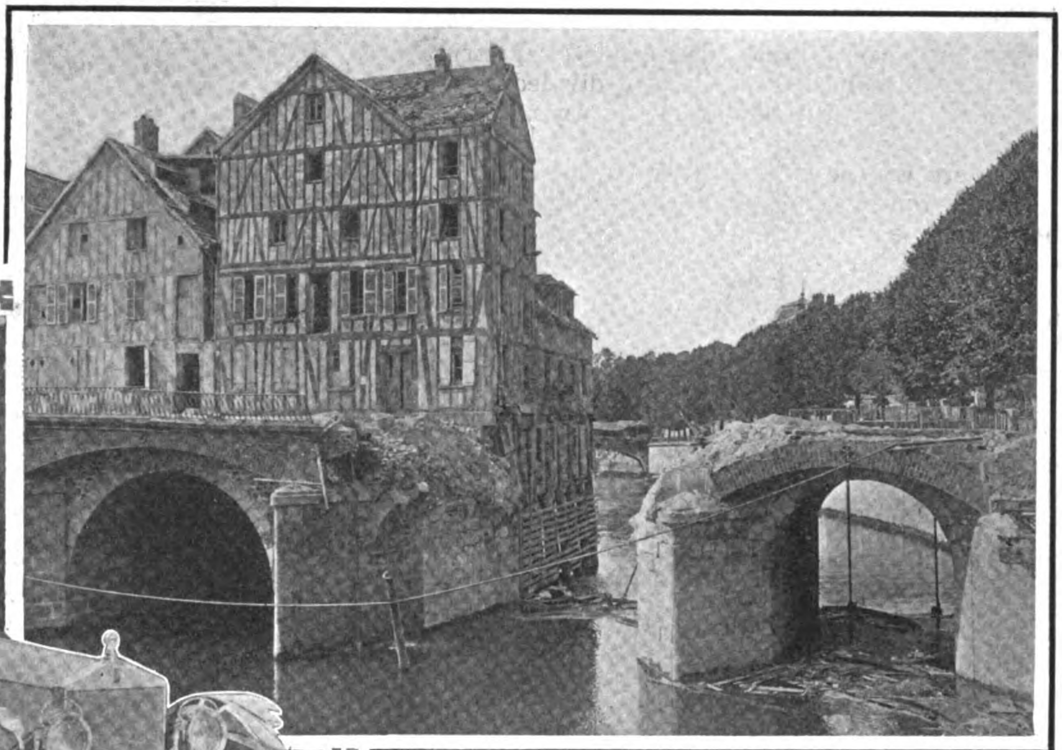
Making War Supplies

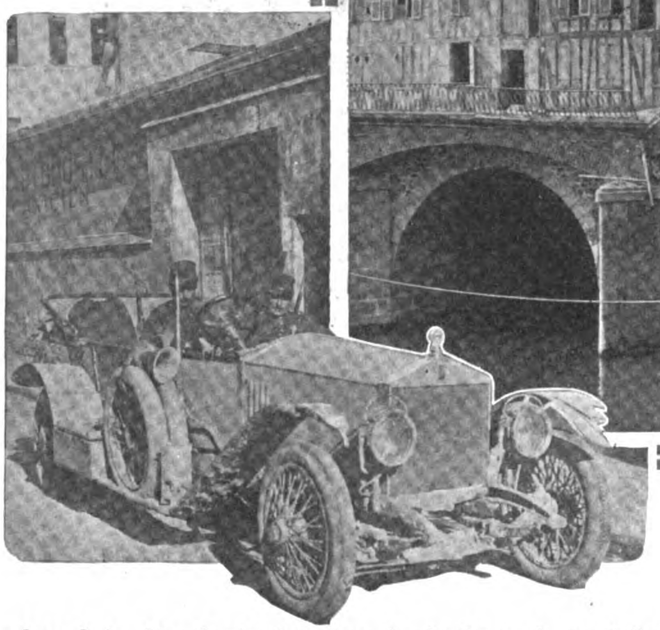
Most of the firms making touring cars only are undertaking work for the commercial motor manufacturers or are machining parts for the government arsenals. Shells, bombs, aeroplane darts, guns and gun fittings are being turned out in big quantities in some of the leading factories.

To Paris for Repairs

The repair departments of all factories are having a busy time. No conditions are more strenuous than those pertaining in war, and as the scene of the fighting is still very near Paris, cars are frequently sent into the capital to be repaired instead of being turned over to the traveling workshops. This work is not very satisfactory from the manufacturers' standpoint, for it is spasmodic and has to be got through in the shortest possible time. It has the advantage, however, of enabling staffs to be kept together. The skilled mechanics who have not been called up for war service have very little difficulty in finding work. In addition to those em-

Right — Wrecked bridge over the river Marne at Meaux, a scene of the recent hostilities between the Germans and the Allied armies. This is an important touring center for automobilists





Left—The brothers Georges and Maurice Sizaire on their Sizaire-Berwick car just returned from the front in France. Note the tattered condition of the wooden fenders, which is typical of the indifference to appearance of automobiles in army service

ployed in the factories, hundreds have been taken on at the various government arsenals.

Hard to Keep Staffs

Unskilled laborers are in a much less favorable condition. As it is believed, even by optimists, that this war will continue until the spring, workers are settling down to new conditions, taking up whatever work they can find, rather than wait for a resumption in the factories where they were formerly employed. This means that men will become scattered and it will be harder to get staffs together than was originally imagined.

No Cars for Public

There has been no repeal of the law against the exportation of automobiles, but the authorities are now willing to give permits in individual cases for cars to be sent out of the country. This is enabling factories with stocks to get their machines into England for the English or Colonial market. The volume of business done in this way, however, is small, for only cars which were completed or very near completion when the war broke out can be sent abroad. No factory in France has sufficient staffs to enable it to produce touring cars. Needless to say, the demand for touring cars at home is nil. It may be stated with certainty that not a dozen cars have been delivered to private customers in France since the war broke out.

Most Factories Near Paris

When Paris was in danger of being invested by the Germans, several of the automobile factories doing Government work were removed to the provinces. The Renault aviation motor section was taken to Lyons; Gnome went to Bordeaux; Clerget to Tours; Hotchkiss to Toulouse, etc. The entry of the enemy into Paris—we who live in the city have only just realized how closely we escaped this entry—would have had more than a moral effect. Nine-tenths of French automobiles are produced around Paris, and to have isolated this enormous source of supply from the army would have had a most disastrous effect. Now that the danger of an advance on Paris appears to be at an end, arrangements are being made for the removed branches to be returned to the city.

No French 1915 Models

Automobile manufacturers have not yet been able to size up how the industry will stand when the war is over. Although there is a firm conviction that the Allies will triumph, men of knowledge do not look for an easy victory. Many are of the opinion that the war will last throughout the winter and may come to an end in the spring. It can be accepted as certain that there will be no 1915 models. Supposing work is resumed in the early months of 1915, manufacturers will continue to produce the cars they were offering during 1914. The new types which should have been presented in the Grand Palais this month will be put forth as 1916 models. It is hardly necessary to state that there will be no automobile show in Paris before the end of 1915. Even England, which is much better placed than France, owing to the absence of conscription, has decided to drop its automobile show at Olympia this year.

Already 1915 is looked upon as a dead year, or a go-between year. Trade may spring up briskly after the war—business men are divided on this point—but there will be so much reorganization to do, there will be so much time lost in getting supplies, there will be so much delay in settling down to the old routine, that 1915 cannot under any circumstances be a brilliant year. Most men in the industry are of the opinion that there will be a period of retrenchment which will last fully a year after the declaration of peace.

State Owns 70 Per Cent. of Cars

One complicated phase of the situation is that the Government has become the owner of probably more than half the automobiles in France. No figures are available on this point, but from the opportunities I have had of noting the number of automobiles with the French armies and in army garages in various parts of the country, I am of the opinion that the State has purchased fully 70 per cent. of all machines above 12 horsepower. The army does not need all these machines on a peace footing—indeed there are thousands at the present time kept in reserve owing to the inability to use them with the troops—and when hostilities come to a close they must be disposed of. There will be a considerable wastage, for war is almost as great a destroyer of automobiles as of men.

Already the countryside is dotted with wrecked automobiles. Further there will be hundreds of cars which cannot go into private service until they have received a complete overhaul. Whether the damaged machines will be scrapped and the good ones kept, whether the army will keep them all, or whether it will sell them back to the original owners at a reduced price, is not known. The probabilities are that the last mentioned plan will be adopted. It remains to be seen whether the recuperating powers of the French nation are sufficient for it to replace its shortened supply of automobiles immediately or not.

To Refuse German Cars

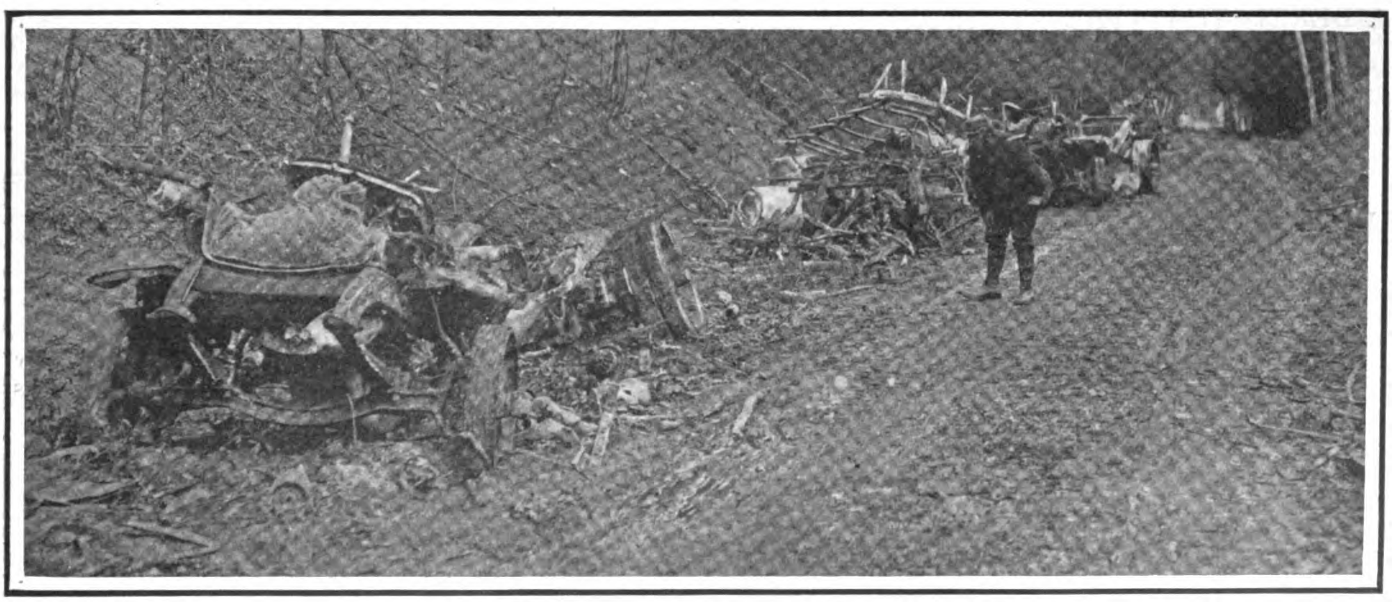
It may be taken that there will be an absolute refusal on the part of both France and England to accept any German automobile products for a long time after this war. This is already felt in England; it is not felt in France for the moment because France is not a buyer. No Frenchman or Englishman will want to own a German automobile, to use German tires, or to have on his car any German part if it can be produced elsewhere. At the present time there are no German companies in France. The Government stepped in and requisitioned all the Continental tires; it has taken possession of the Bosch factory in Paris; it has seized all German cars, and if there is any German business man in France at this time he must be in some position inaccessible to the police.

Germany Trade Not Wanted

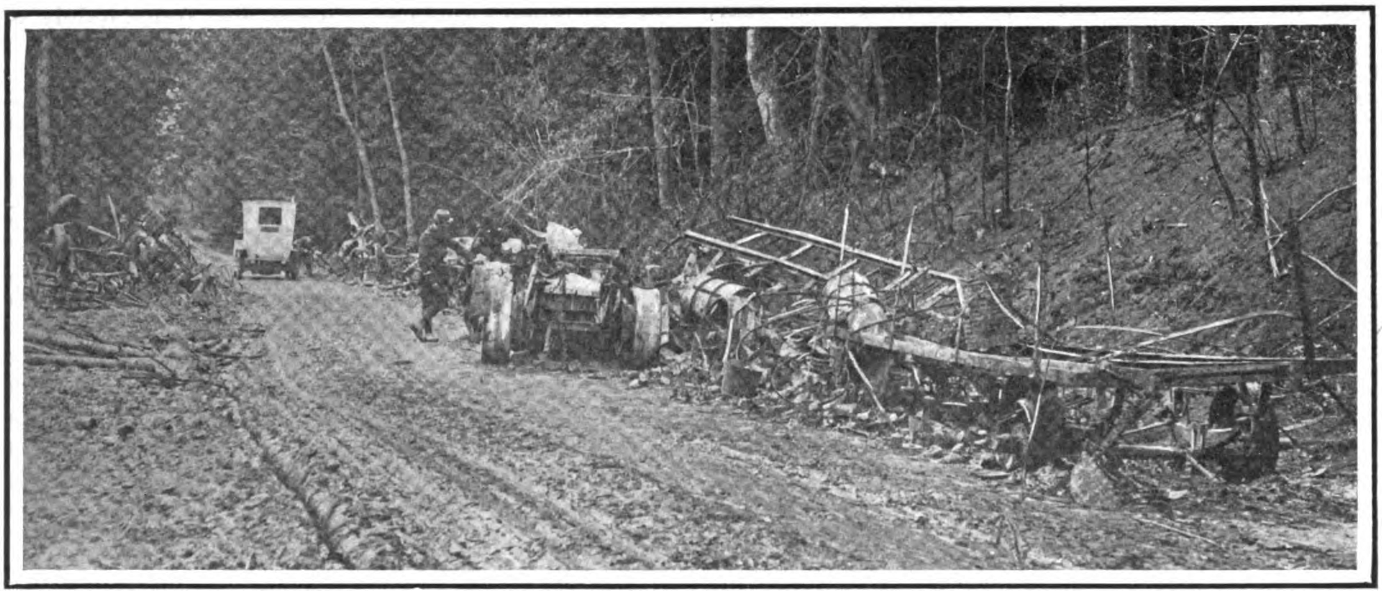
In England conditions are different; but even there the feeling is so strong that owners of German names are making frantic efforts to have them changed at the shortest possible notice and firms with German connections and German capital are trying to purify themselves in the eyes of John Bull. German trade does not need capturing: it is being thrown into the hands of British and French manufacturers.

Germany Has Magneto Supply

The most important feature of this business war is the magneto supply. Germany has made such advances in this connection that she has captured 90 per cent. of the magneto business in France and England. It is unanimously conceded that the two countries ought to get this business back. France is too busy driving the enemy out of her territory to trouble about this matter; but even England does



Another view of the German motor truck convoy which was surprised and destroyed by the French in the forest of Villers-Cotteret. The driver of the first truck was killed by a well-directed rifle shot and his vehicle zigzagged across the road so that the trucks following collided with it. Several of these vehicles capsized and a number of them took fire. In a very short time the entire convoy was reduced to a twisted mass of iron and wreckage hardly recognizable as the remains of efficient, powerful motor vehicles



The German motor convoy destroyed by the French troops in the forest of Villers-Cotteret during the fighting between the Allied Armies and Germans in France. Note the manner in which the ruined motor trucks have been thrown off the road

not appear to be handling the matter in as broad a manner as it justifies. The British Thomson-Houston Co. has decided to go into the magneto business, Vandervelt and a few others are doing the same, but the efforts are timid ones.
